Sunday, March 17, 2013 2:30PM - 5:30PM –

Session 1A Industrial Physics Forum: Innovation and Entrepreneurship Ballroom IV - David Seiler, National Institute of Standards and Technology

2:30PM 1A.00001 DARPA Loves Its Physicists ROBERT COLWELL, DARPA — DARPA's Microsystems Technology Office, MTO, conceives and develops a wide range of technologies to benefit the US warfighter, from exotic GaN transistors to high-power fiber lasers, highly efficient embedded computer systems to synthetic biology. MTO has world class electrical and mechanical engineers, but we also have a cadre of extremely capable physicists, whose complementary skillset has been absolutely essential to identifying promising technological avenues for the office and for the agency. In this talk I will explain the DARPA model of technology development, using real examples from MTO, highlighting programs where physics-based insights have led to important new capabilities for the Dept of Defense.

3:06PM 1A.00002 NASA technology investments: building America's future , MASON PECK, NASA Chief Technologist — Investments in technology and innovation enable new space missions, stimulate the economy, contribute to the nation's global competitiveness, and inspire America's next generation of scientists, engineers and astronauts. Chief Technologist Mason Peck will provide an overview of NASA's ambitious program of space exploration that builds on new technologies, as well as proven capabilities, as it expands humanity's reach into the solar system while providing broadly-applicable benefits here on Earth. Peck also will discuss efforts of the Office of the Chief Technologist to coordinate the agency's overall technology portfolio, identifying development needs, ensuring synergy and reducing duplication, while furthering the national initiatives as outlined by President Obama's Office of Science and Technology Policy. By coordinating technology programs within NASA, Peck's office facilitates integration of available and new technology into operational systems that support specific human-exploration missions, science missions, and aeronautics. The office also engages other government agencies and the larger aerospace community to develop partnerships in areas of mutual interest that could lead to new breakthrough capabilities. NASA technology transfer translates our air and space missions into societal benefits for people everywhere. Peck will highlight NASA's use of technology transfer and commercialization to help American entrepreneurs and innovators develop technological solutions that stimulate the growth of the innovation economy by creating new products and services, new business and industries and high quality, sustainable jobs.

3:42PM 1A.00003 Innovation Driver Nanoelectronics , HUBERT LAKNER, Fraunhofer-Gesellschaft Group for Microelectronics and IPMS — When addressing the global societal challenges most solutions will require $Nanoelectronics$ and $SmartSystems$ - therefore innovation today is mainly based on nanoelectronics which has become one of the most important key enabling technologies and innovation drivers. Nanoelectronics has been extended by other microtechnologies. This results in additional functionalities. The combination of analog and digital electronics, the integration of sensors and actuators, of power devices and rf components on wafer level makes it possible to shrink shoebox sized systems to the size of a matchbox. But there is no innovation without research. Europe (Germany) is top in invention but poor in commercialization - many good ideas fail when going from research to production within the so-called Valley of Death. To overcome this, a clear strategy is necessary. Silicon Saxony, the big Saxonian cluster on micro- and nanoelectronics is presented as a best practice example: clear focus, addressing whole value chains and establishing joint technology platforms has led to a remarkable commercial success in the Dresden area.

4:18PM 1A.00004 Physics and Entrepreneurship: A Small Business Perspective , JASON CLEVELAND, Asylum Research —

4:54PM 1A.00005 Physics and Innovation: A Large-Company Perspective , ROBERT DOERING, Texas Instruments — With regard to its influence on *innovation* (i.e., creating new commercial technologies), physics continuously faces the challenge of "keeping ahead of engineering" and "moving on" to new concepts as well as to potentially new roles with respect to industrial research. For most large companies, the R&D model has undergone significant transformation over the past three decades. This has been driven, in part, by the increasing cost of continuously developing new technologies upon which to base state-of-the-art products. Part of this challenge is to select which new concepts and "emerging technologies" to pursue. A poor decision at this point wastes development resources and can be very difficult to overcome later. Therefore, a key feature of many new R&D models is collaboration with entities outside of the corporation. Such partnerships reduce both the cost and risk of exploring multiple lines of research which may lead to new technologies. One flexible approach to organizing R&D partnerships is via the establishment of a consortium. The semiconductor industry has successfully used research consortia since the founding of the Semiconductor Research Corporation (SRC) in 1982 and SEMATECH a few years later. The automotive industry has also used the consortium approach for many years since the formation of the United States Council for Automotive Research (USCAR) in 1992. In the case of the SRC, the principal operating methodology is for the members to create requests for proposals leading to the collective funding of university research. This is often done in partnership with federal agencies. For example, the Focus Center Research Program (FCRP, an SRC subsidiary) is co-funded with DARPA. Another SRC subsidiary, the Nanoelectronics Research Initiative (NRI) is jointly supported with the NSF and NIST. This NRI-agency partnership has partly been enabled by the National Nanotechnology Initiative's Signature Initiative on "Nanoelectronics for 2020 and Beyond." Within the SRC portfolio, the NRI research is particularly "physics intensive"! Of course, in addition to consortia, the new models typically include external R&D through consulting arrangements, IP licensing, and acquisition of smaller companies that have developed useful new technologies, supported in some cases by SBIRs and other forms of government investment in growth of the economy.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A1 DCMP GMAG: Invited Session: Spin Caloritronics Ballroom I - Kai Liu, University of California, Davis

8:00AM A1.00001 Longitudinal Spin Seebeck Effect

, EIJI SAITOH, Institute for Materials Research, Tohoku University — The spin Seebeck effect (SSE) refers to the generation of a spin voltage as a result of a temperature gradient in magnetic materials [1-7]. Here, a spin voltage is a potential for electron spins to drive a nonequilibrium spin current; when a conductor is attached to a magnet with a finite spin voltage, it induces a spin injection into the conductor. The SSE is of crucial importance in spintronics and spin caloritronics, since it enables simple and versatile generation of a spin current from heat. The simplest and most straightforward setup of the SSE is the longitudinal configuration [4], in which a spin current flowing parallel to a temperature gradient is measured via the inverse spin Hall effect (ISHE). The longitudinal SSE device consists of a ferromagnetic or ferrimagnetic insulator (FI, e.g. YIG) covered with a paramagnetic metal (PM, e.g. Pt) film. When a temperature gradient is applied perpendicular to the FI/PM interface, an ISHE-induced voltage is generated in the PM layer. In this talk, we report the observation of the longitudinal SSE in various FI/PM systems and provide evidence that the longitudinal SSE is free from thermoelectric artefact [7], i.e., the anomalous Nernst effect caused by extrinsic magnetic proximity [8]. Then, we discuss the longitudinal SSE from an application point of view [6]. We thank E. Saitoh, S. Maekawa, G. E. W. Bauer, X.-F. Jin, H. Adachi, D. Hou, D. Tian, T. Kikkawa, A. Kirihara, and M. Ishida for their support and valuable discussions.

8:36AM A1.00002 Transport Magnetic Proximity Effects in Platinum

, SSU-YEN HUANG, The Johns Hopkins University, National Tsing Hua University — Platinum (Pt) metal, being non-magnetic and having a strong spin-orbit coupling interaction, has been central in detecting pure spin current and establishing most of the recent spin-based phenomena. Thus, it is important to ascertain the transport and magnetic characteristics of thin Pt films in contact with a ferromagnet. In this work, we use both electric and thermal means to conclusively show the transport magnetic proximity effects (MPE) of thin Pt film in contact with ferromagnetic insulator YIG. At thicknesses comparable to, and less than, the spin diffusion length, the strong ferromagnetic characteristics in Pt films on YIG are indistinguishable from those of ferromagnetic permalloy on YIG. [1] The MPE occurs at the interface and decreases exponentially away from the interface, concentrating in only a few monolayers. As a result, the pure spin current detected by a thin Pt is tainted with a spin polarized current. The pure spin current phenomena, such as the inverse spin Hall effect and the spin Seebeck effect, have been contaminated with the anomalous Hall effect and the anomalous Nernst effect respectively. These results raise serious questions about the suitability, and the validity, of using Pt in establishing pure spin current phenomena; on the other hand, a much stronger spin-based effect can be induced by the MPE at the interface. This research is in collaboration with X. Fin, Y. P. Chen, J. Wu, and J. Q. Xiao (University of Delaware), T. Y. Chen (Arizona State University) and D. Qu, W. G. Wang, and C. L. Chien (The Johns Hopkins University).

9:12AM A1.00003 Observation of the planar Nernst effect in Permalloy and Nickel Thin Films with In-plane Thermal Gradients[1]

, BARRY ZINK, University of Denver — The reliable generation of pure spin currents is an important ingredient in future spintronic circuits that may offer lower power consumption and greater processing capabilities than current technology. Over the past few years some groups have reported that such a spin current can be generated simply by applying a thermal gradient to a ferromagnetic material. This effect, called the spin Seebeck effect (SSE), has generated tremendous interest in the interaction of heat, charge and spin in ferromagnetic systems. In this talk we will present our own recent measurements of thermoelectric and thermomagnetic effects in thin film metallic ferromagnets. These are enabled by a micromachined thermal isolation platform that removes potentially confounding effects introduced in such measurements by the presence of a highly thermally conductive bulk substrate. One of the main results is the observation of a transverse thermopower, called the planar Nernst effect (PNE), that is caused by spin-dependent scattering. This PNE should therefore be present in any attempted measurement of the SSE in a metal system where spin-dependent scattering of electrons occurs. Furthermore our "zero substrate" experiment shows no signal with the expected symmetry of the SSE, suggesting that the presence of the substrate is required to cause such a signal. Further experiments are required to determine if a pure spin current is actually involved in the generation of the signal associated with the SSE in ferromagnetic metal films. This work was performed in collaboration with A. D. Avery, and M. R. Pufall.

9:48AM A1.00004 Non-universal shot noise in quasiequilibrium spin valves

, TERO HEIKKILA, Aalto University — Shot noise can be used as a diagnostic tool characterizing mesoscopic wires, especially the inelastic scattering in them. This characterization is based on the fact that in the absence of inelastic scattering that carries the energy away from the system, disordered wires are described by a universal Fano factor defined as the ratio of the noise power and the average current. In particular, the value of this Fano factor is invariant even for wires with non-uniform conductivity. We show that this universality breaks down in spin valves with strong electron-electron scattering. The reason for this breakdown is that the inter-spin energy relaxation due to electron-electron scattering in the absence of inter-spin charge relaxation breaks the Wiedemann-Franz relation between charge and heat conductivity. In particular, we predict that the Fano factor gets strongly suppressed for the antiparallel configuration of magnetizations.

T.T. Heikkilä and K.E. Nagaev, arXiv:1302.1372

10:24AM A1.00005 Charge Voltages from Magnetization Dynamics[1] , AXEL HOFFMANN[2], Materials Science Division, Argonne National Laboratory — The main challenge of spin caloritronics is to establish a connection between heat currents and spin currents. Towards this end, spin Hall effects have become very important, since they allow to convert a pure spin current into a transverse charge voltage. I will show how these spin Hall effects can be characterized with great accuracy using spin pumping, where the excitation of ferromagnetic resonance generates a pure spin current in an adjacent non-magnetic conductor.[3] The change in the line-width of the ferromagnetic resonance determines the spin-mixing conductance and thus after proper calibration of the *rf* magnetic fields and the concomitant opening angles of the magnetization precession, allows to determine the magnitude of the spin current. The charge current generated from inverse spin Hall effect is measured through the associated electrical voltage and the ration of spin and charge current directly determines the spin Hall angle. Furthermore I will present an alternative approach for converting magnetization dynamics into measurable charge voltages. Namely, the dissipation of magnetization dynamics in thin films generally also results in a temperature gradient perpendicular to the film, since the supporting substrate acts as a heat sink. This in turn can generate a transverse voltage through the anomalous Nernst effect. Interestingly this allows to detect spin waves with very good signal to noise[4] and unlike optical or inductive detection techniques there is practically no lower limit for the wavelength of the detected spin waves.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A2 DCMP: Invited Session: Novel Superconductivity in FE Selenide Superconductors

Ballroom II - Douglas Scalapino, University of California at Santa Barbara

8:00AM A2.00001 Ab initio calculations and crystal symmetry considerations for novel FeSe-based superconductors , IGOR MAZIN, NRL — Density functional calculations disagree with the ARPES measurements on both $K_{0.3}Fe_2Se_2$ superconducting phase and $FeSe/SrTiO_3$ monolayers. Yet they can still be dramatically useful for the reason that they respect full crystallographic symmetry and take good account of electron-ion interaction. Using just symmetry analysis, it is shown that nodeless d-wave superconductivity is not an option in these systems, and a microscopic framework is derived that leads to a novel s-wave sign-reversal state, qualitatively different from the already familiar $s_{\pm}$ state in pnictides and bulk binary selenides. Regarding the FeSe monolayer, bonding and charge transfer between the film and the substrate is analyzed and it is shown that the former is weak and the latter negligible, which sets important restrictions on possible mechanisms of doping and superconductivity in these monolayers. In particular, the role of the so-called "Se etching," necessary for superconductivity in FeSe monolayers, is analyzed in terms of electronic structure and bonding with the substrate.

8:36AM A2.00002 Scanning tunneling microscopy study on superconductivity of FeSe thin films , XUCUN MA, Institute of Physics, Chinese Academy of Sciences — Searching for superconducting materials with high transition temperature (T_C) is one of the most exciting and challenging fields in physics and materials science. By using MBE technique, we are able to prepare stoichiometric and superconducting FeSe single crystalline films on various substrates, which enables us investigate superconductivity mechanism of FeSe thin films in well-controlled way [1-3]. Most importantly, by using low temperature scanning tunneling spectroscopy, a superconductive gap as large as 20 meV and the vortex state under high magnetic field are revealed in the single unit-cell thick FeSe films on $SrTiO_3$(001) substrate [4]. Such a high Tc superconductor is further confirmed by recent transport measurement. The study not only demonstrates a powerful way for finding new superconductors and for raising T_C, but also provides a well-defined platform for systematic study of the mechanism of unconventional superconductivity by using different superconducting materials and substrates. The study is collaborated with Professor Qi-Kun Xue, Department of Physics, Tsinghua University, China.

9:12AM A2.00003 Phase Diagram and High Temperature Superconductivity at 65K in the Single-Layer FeSe Films Revealed by ARPES[1] , SHAOLONG HE, National Lab for Superconductivity,Institute of Physics,CAS,Beijing — The discovery of the iron-based superconductors in 2008 not only provides another venue to understand the origin of high-Tc superconductivity but also a new playground to explore novel superconductors with higher superconducting transition temperature. The latest report of possible high temperature superconductivity in the single-layer FeSe films grown on SrTiO3 substrate is both surprising and interesting [1]. In this talk, we report the electronic structure and phase diagram of the single-layer FeSe films by angle-resolved photoemission spectroscopy (ARPES) [2,3]. Our high-resolution ARPES results show that it has a simple Fermi surface topology consisting only of electron pockets near the zone corner without indication of any Fermi surface around the zone center. In addition, our observation of large and nearly isotropic superconducting gap in this strictly two-dimensional system rules out existence of node in the superconducting gap. We also established a phase diagram in this single-layer FeSe films by an annealing procedure to tune the charge carrier concentration over a wide range. By optimizing the annealing process, we observed evidence of a record high Tc of $\sim$ 65K in the single-layer FeSe films. The wide tunability of the system across different phases, and its high-Tc, make the single-layer FeSe film ideal not only to investigate the superconductivity physics and mechanism, but also to study novel quantum phenomena and for potential applications.

9:48AM A2.00004 Pairing and Fermiology in iron-chalcogenide superconductors , DUNG-HAI LEE, Dept. Physics, University of California, Berkeley — "Stripe"-type magnetic fluctuations has been postulated as the trigger of Cooper pairing in iron-based superconductors. In iron pnictides the matching of the peak magnetic fluctuations wavevector and the Fermiology lands support to the above idea. However recent ARPES results on high T_c $A_xFe_{2-y}Se_2$ and $FeSe/SrTiO_3$ and neutron results on $A_xFe_{2-y}Se_2$ pose challenges to the above picture. In this talk we will take a fresh new look at the purported pairing mechanism of iron-based superconductors.

10:24AM A2.00005 S_4 Symmetric Microscopic Model for Iron Based Superconductors , JIANGPING HU, Institute of Physics, CAS, China and Department of Physics, Purdue University — How are cuprates and iron-based high temperature superconductors correlated? What is the common mechanism behind two different families of iron-based superconductors, iron-pnicitides and iron-chalcogenides? These two questions are two major challenges in the today's field of high temperature superconductors. In this talk, we will show when the lattice symmetry, the $\mathbf{S_4}$ symmetry, of the building block, the tri-layer structure of FeAs or FeSe, is properly considered, the low energy physics of iron-based superconductors is governed by a two-orbital Hamiltonian near half filling that can be divided two weakly coupled one-orbital model. We will discuss the microscopic origin and some unique properties of the model, including magnetism and pairing symmetry. The model provides a unified understanding of iron pnictides and iron chalcogenides, and suggests that cuprates and iron-based superconductors share an identical high-T_c superconducting mechanism. The model leads to a natural classification of pairing symmetry according to $\mathbf{S_4}$ symmetry. When the pairing is driven by antiferromagnetic exchange couplings, there are two different s-wave states. One s-wave is the well-studied s$\pm$ pairing which is in the A phase of $\mathbf{S_4}$ symmetry (even under $\mathbf{S_4}$ symmetry operation), and the other is a new type of extended s-wave pairing which is in the B phase of $\mathbf{S_4}$ symmetry (odd under$\mathbf{S_4}$ symmetry operation). The superconductivity order in the B phase are characterized by opposite signs between up and bottom As(Se) layers in the trilayer Fe-As(Se) structure. The 122 Iron-chalcogenides and the single layer FeSe are most likely in the B-phase. We believe that the model establishes a new foundation for exploring novel properties of iron based superconductors.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A3 DCMP: Invited Session: Second Landau Level: Quantum Phases Ballroom III - Loren Pfeiffer, Princeton University

8:00AM A3.00001 Evidence of low-lying gapped excitations in the ν =5/2 quantum fluid[1] , URSULA WURSTBAUER, Columbia University — The competition between quantum phases that dictate the physics in the second Landau level (SLL) results in striking phenomena. A highly fascinating state is the even denominator fractional quantum Hall (FQHE) state at filling ν =5/2 that is widely believed to support non-Abelian quasi-particle excitations. Our work explores the low-lying neutral excitation modes in the SLL by resonant inelastic light scattering measurements. At 5/2 the spectra revealed a band of gapped modes with peak intensity at energy of 0.07meV. These modes are interpreted as a roton minimum in the wave vector dispersion of spin-conserving excitations. The intensity of the roton band significantly diminishes by increasing the temperature to 250mK and it fully collapses for T> 250mK. This temperature dependence is consistent with activated magneto-transport of the incompressible quantum fluid at 5/2. A long wavelength spin wave mode (SW) is seen at the bare Zeeman energy, indicating that there is non-zero spin-polarization. Both, roton and SW modes appear only in a very narrow filling factor range of less than $\nu < 5/2 \pm 0.01$. A gapless continuum of low-lying excitations emerges at filling factors slightly away from 5/2. This demonstrates a transition from an incompressible quantum Hall fluid at exactly ν =5/2 to compressible states at very close filling factors. This work is in collaboration with A. Pinczuk, A. Levy, K. West, L. Pfeiffer, S. Mondal, J. Watson and M. Manfra.

[1]Supported by the U.S. National Science Foundation and the Alexander von Humboldt Foundation.

8:36AM A3.00002 Spin transition in the second Landau level[1] , W. PAN, Sandia National Labs — The fractional quantum Hall effect (FQHE) states in the second Landau level have attracted growing interest and intensive theoretical and experimental investigations due to their being non-Abelian states. Recently, we systematically examined the spin polarization of the 8/3 and 12/5 states in a series of high quality two dimensional electron systems. Evidence of spin transition was observed for both states, suggesting a more complicated nature of the FQHE ground states in the second Landau level.

[1]SNL is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:12AM A3.00003 Quantum Hall Interferometry and Detection of Anyonic Braiding Statistics , STEVEN SIMON, Oxford University — In two spatial dimensions quantum mechanical particles are not limited to being bosons or fermions as they are in three dimensions, but can be particles known as anyons. Such anyons come in two major varieties — Abelian and non-Abelian — both of which were long ago predicted to be realized in certain Fractional Quantum Hall (FQH) systems. However, experimental demonstration of anyonic braiding properties has remained elusive and very controversial. New results by Willett et. al. and Kang et. al. have been interpreted as evidence of anyonic braiding in Fabry Perot interferometers in the second Landau level. In this talk, I will discuss my current understanding of these works based on a number of recent publications.

9:48AM A3.00004 Quantifying disorder and its impact in the 2nd Landau level[1] , MICHAEL MANFRA, Purdue University — Strong electronic correlations are evident in the 2nd Landau level (LL) of an ultra-high quality GaAs/AlGaAs two-dimensional electron gas (2DEG). The exotic fractional quantum Hall states at filling factors ν =5/2 and 12/5, as well as the reentrant integer quantum Hall states flanking half-filling, are a few examples presently under intense investigation. While it is generally accepted that samples must be of extremely low disorder to exhibit correlations in the 2nd LL, our understanding of how to quantify residual disorder and its impact on the states of interest remains primitive. In this talk we will critically examine how disorder is quantified for the 2DEG both at zero magnetic field and in the quantum Hall regime, and then compare the results of this analysis with measurements of the excitation gap at ν =5/2 in samples in which disorder is varied in a well-defined manner. Our results highlight the very different impact on the excitation gap generated by different types of disorder and the limitations of presently employed characterization methods.

[1]Work done in collaboration with the Csathy group, Purdue University

10:24AM A3.00005 Role of inter-composite fermion interactions in fractional quantum Hall effect[1] , JAINENDRA JAIN, Penn State University — One of the important challenges in the field of the fractional quantum Hall effect (FQHE) is to understand the nature of states that cannot be explained as integer quantum Hall effect of weakly interacting composite fermions; such states include FQHE at 5/2, 7/3, 8/3, 12/5, 13/5, 19/8 in the second Landau level (of GaAs) and 4/11, 5/13, 3/8(?) in the lowest Landau level. I will report on results [1,2] that demonstrate that multipartite wave functions of composite fermions provide an excellent account of the low energy physics of the model 3-body and 4-body interaction Hamiltonians that have the Pfaffian and the Read-Rezayi wave functions as their exact ground states. The relevance of these wave functions to the Coulomb solutions at 5/2 and 13/5 is investigated through an adiabatic scheme connecting the two models. In particular, the multipartite wave functions are shown to shed light on the structure of the neutral and charged excitations and of unpaired composite fermions [1]. We find that the residual interaction between composite fermions also has substantial effect at certain other fractions; it is predicted to produce a paired FQHE of the anti-Pfaffian kind at 3/8 [3], and unconventional trion excitations at 7/3 [4].

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A4 Industrial Physics Forum: Frontiers in Physics Ballroom IV - David Seiler, National Institute of Standards and Technology

8:00AM A4.00001 Has the Higgs Boson Been Discovered? Latest Results from the ATLAS Experiment at the LHC[1] , MICHAEL TUTS, Columbia University — The Large Hadron Collider (LHC) at CERN has had a very successful first data taking run that ended in December 2012. The ATLAS detector has collected about 25 fb^{-1} of integrated luminosity of proton-proton collisions at a center-of-mass energy of 8 TeV. The LHC is the highest energy particle accelerator in the world. The highest profile result has been the announcement of the discovery of a new particle at a mass of about 125 GeV/c^2, consistent with the long sought Higgs Boson. I will start by describing why there is such excitement about this discovery and why it is not just "another" new particle – if it is indeed the Higgs Boson, it is not only the last missing piece of the Standard Model, but represents a fundamentally new type of particle. The discovery comes after almost two decades of construction of the particle accelerator (LHC) and some of the most complex scientific instruments ever built. I will focus on and describe the ATLAS detector and how it works. The ATLAS experiment, together with CMS experiment, announced the discovery of this new particle in July 2012. I will present the latest results on the properties of this new "Higgs-like" particle and the prospects for future discoveries at the LHC.

8:36AM A4.00002 Entangled magnetism: synthesis, detection, and potential applications , COLLIN BROHOLM, Johns Hopkins University — I describe recent progress towards a radically different form of magnetism rooted in the phenomenon of entanglement with potential applications in energy and information technologies. In conventional magnetic materials atomic magnetic moments (spins) develop a static pattern when cooled below a critical temperature. However, by carefully selecting the crystalline and electronic structure, it is possible to stabilize a spin-liquid where spins correlate without developing fixed orientations. I shall describe neutron scattering experiments on such materials that probe quantum entanglement and provide evidence for emergent quasi-particles. These are stable interacting entities created as energy is imparted to the spin liquid. Entangled spin liquids may underlie high temperature superconductivity and their quasi-particles might eventuall be exploited for information processing.

9:12AM A4.00003 Quantum Computing , MATTHIAS STEFFEN, IBM — Quantum mechanics plays a crucial role in many day-to-day products, and has been successfully used to explain a wide variety of observations in Physics. While some quantum effects such as tunneling limit the degree to which modern CMOS devices can be scaled to ever reducing dimensions, others may potentially be exploited to build an entirely new computing architecture: The quantum computer. In this talk I will review several basic concepts of a quantum computer. Why quantum computing and how do we do it? What is the status of several (but not all) approaches towards building a quantum computer, including IBM's approach using superconducting qubits? And what will it take to build a functional machine? The promise is that a quantum computer could solve certain interesting computational problems such as factoring using exponentially fewer computational steps than classical systems. Although the most sophisticated modern quantum computing experiments to date do not outperform simple classical computations, it is increasingly becoming clear that small scale demonstrations with as many as 100 qubits are beginning to be within reach over the next several years. Such a demonstration would undoubtedly be a thrilling feat, and usher in a new era of controllably testing quantum mechanics or quantum computing aspects. At the minimum, future demonstrations will shed much light on what lies ahead.

9:48AM A4.00004 Catching the Light: the Giant Magellan Telescope , DANIEL FABRICANT, Harvard Center for Astrophysics — There has been an explosion of theoretical work outlining how the first galaxies might have formed 13 billion years ago. The Giant Magellan Telescope (GMT) is to be the first of three extremely large ground-based telescopes capable of confronting theory with detailed observations of primordial galaxies. With a collecting area approaching 400 square meters and adaptive optics to remove the image blurring of the earth's turbulent atmosphere, the GMT offers a huge leap in sensitivity over the largest existing telescopes. Building a high-performance telescope of this scale relies on recent technical advances in optics and electronics. I describe the major technical challenges addressed in the GMT's design, and offer a glimpse of ground-based astronomy with extremely large telescopes a decade hence.

10:24AM A4.00005 Frontiers of the Physics of Carbon Nanotubes , MILDRED DRESSELHAUS, MIT — Carbon nanotubes entered the scene of materials physics about 20 years ago, exhibiting unusual structures and properties stemming from their strong sp2 carbon bonds, their lower mass density, their very large length-to-diameter ratio, and their ability to be either semiconducting or metallic depending on their tube diameter and the orientation of their in-plane hexagons relative to their tube axis. You might ask what potential applications could be envisioned for such unusual nano structures, and what practical application have in fact been realized to date. This will be the focus of my presentation.

Monday, March 18, 2013 8:00AM - 10:36AM –

Session A5 DMP: Focus Session: Van der Waals Bonding in Advanced Materials - Materials Behavior 301 - Roberto Car, Princeton University

8:00AM A5.00001 Beyond RPA correlation energies: Evaluation of model exchange-correlation kernels[1]

, DEYU LU, Center for Functional Nanomaterials, Brookhaven National Laboratory — The adiabatic-connection fluctuation-dissipation theorem (ACFDT) has drawn considerable attention in describing van der Waals (vdW) dispersion interactions. Under the random phase approximation (RPA), the EXX/RPA method yields the correct asymptotic behavior at large distances. However, for many advanced materials, e.g., organic/inorganic interfaces and molecular crystals, it is important to capture the short-range dispersion interaction within several angstrom. Because RPA pair distribution function is incorrect at short distances, the contribution of the exchange-correlation kernel has to be included properly. In this work, we implemented several model exchange-correlation kernels in the framework of ACFDT. Special attention was paid to develop non-local kernels suitable for inhomogeneous electronic systems. The performance of the exchange-correlation kernels were evaluated for both bulk and molecular systems.

[1]Research carried out (in whole or in part) at the Center for Functional Nanomaterials, Brookhaven National Laboratory, which is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

8:12AM A5.00002 Long-range van der Waals interaction between nanoclusters[1]

, JIANMIN TAO, JOHN PERDEW, ADRIENN RUZSINSZKY, Tulane University — van der Waals (vdW) interaction is an important long-range correlation that affects many properties of materials. However, this effect cannot be accurately accounted for by first-principles calculations, due to computational challenges. Recently, we have developed a model for the vdW coefficients between quasispherical clusters such as fullerenes, sodium and silicon clusters. Our study shows that the widely-used atom-pairwise interaction picture surprisingly breaks down. A quick remedy of this problem leads to a counterintuitive scaling law of the vdW coefficients for caged molecules and clusters.

8:24AM A5.00003 Binding and Diffusion of Lithium in Graphite: Quantum Monte-Carlo benchmarks and validation of van der Waals density functional methods[1]

, PAUL KENT, PANCHAPAKESAN GANESH, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge 37831, JEONGNIM KIM, FERNANDO REBOREDO, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge 37831 — Benchmark diffusion quantum monte-carlo (DMC) studies of the adsorption and diffusion of atomic lithium in graphite are compared with density functional theory (DFT) calculations using several van der Waals methods. The charge transfer is captured adequately with conventional local density functionals. At fixed geometries, these yield surprisingly accurate energetics. In unconstrained geometries, van der Waals corrections are required to correctly reproduce graphite and lithium binding. We find that the empirical method of Grimme et al. only gives correct diffusion barriers when the Li polarizability is reduced to nearly zero, consistent with the charge transfer in the solid-state environment. The Tkatchenko-Scheffler scheme captures the polarizability reduction, yielding accurate results at low computational cost. The self-consistent vdw-DF2 functional yields the best overall results but at increased cost. Slight differences in barrier heights remain with all the DFT approaches compared to the DMC. These results establish a hierarchy of modeling approaches for the lithium-carbon system.

8:36AM A5.00004 Probing van der Waals Forces at the Single-Molecule Level

, LATHA VENKATARAMAN, Columbia University — Single molecule junctions represent an attractive platform to understand and control functionality of materials and devices at the nanoscale. While their electronic transport properties have received tremendous attention thus far, measurements of mechanics are new and allow for a more complete understanding of the structure-function relationship of these atomic scale devices. Here we report simultaneous measurement of force and electrical conductance across Au-Bipyridine-Au junctions using a conducting atomic force microscope (AFM). We show that these junctions have two distinct structures each with a characteristic conductance. Using statistically relevant analysis, these two structures are found to have very different mechanical properties. Specifically, we find that the higher conductance junctions have a significantly larger rupture force and stiffness than the lower conducting junctions. They also have a larger rupture force than Au single-atom point contacts, suggesting multiple points of contact. Using density functional theory simulations we show that van der Waals (vdW) interactions between the pyridine ring and Au electrodes plays a key role in the junction mechanics. These measurements thus provide a quantitative characterization of vdW interactions at metal/organic interfaces at the single-molecule level [1].

9:12AM A5.00005 Liquid water from first principles: The importance of exact exchange, dispersion interactions, and nuclear quantum effects[1]

, ROBERT DISTASIO, ZHAOFENG LI, BISWAJIT SANTRA, Princeton University, XIFAN WU, Temple University, ROBERTO CAR, Princeton University — Quantitative agreement between theory and experiment on the structure of liquid water at ambient conditions has been quite difficult to achieve to date. In this work, we report that highly accurate *ab initio* molecular dynamics simulations of liquid water that account for exact exchange (via the hybrid PBE0 functional [PRB **79**, 085102 (2009)]), dispersion interactions [PRL **102**, 073005 (2009)], and nuclear quantum effects (presently approximated by a 30K increase in the simulation temperature) result in excellent agreement with experiments [PRL **101**, 065502 (2008)]. The importance of each of these effects in the theoretical prediction of the structure of liquid water will be demonstrated by a detailed comparative analysis of the predicted and experimental oxygen-oxygen radial distribution functions. In addition, we will discuss the connection between the experimentally observed scattering intensity, I(k), and the final radial distribution function, g(r), via the structure and form factors.

9:24AM A5.00006 Spatially Resolved Raman Spectroscopy of Single- and Few-Layered WS_2[1]

, AYSE BERKDEMIR, The Pennsylvania State University, HUMBERTO R. GUTIERREZ, University of Louisville, ANDRES R. BOTELLO-MENDEZ, Universite Catholique de Louvain, NESTOR PEREA-LOPEZ, ANA L. ELÍAS, CHENG-ING CHIA, BEI WANG, VINCENT H. CRESPI, FLORENTINO LOPEZ-URIAS, The Pennsylvania State University, JEAN-CHRISTOPHE CHARLIER, Universite Catholique de Louvain, HUMBERTO TERRONES, MAURICIO TERRONES, The Pennsylvania State University — We systematically investigated the Raman scattering of single- and few-layered WS_2 as a function of the number of S-W-S layers and the excitation laser wavelength in the visible range (488, 514 and 647 nm). For the three excitation wavelengths used in this study, the frequency of the $A_{1g}(\Gamma)$ phonon mode monotonically decreases with the number of layers, while the $E^1_{2g}(\Gamma)$ frequency increases. For single-layer WS_2, 514.5 nm excitation generates a second-order Raman resonance for the longitudinal acoustic mode at the M point. This 2LA(M) resonance results from a double-resonant Raman coupling between the electronic band structure and lattice vibrations, an effect not previously seen in any single-layered metal dichalcogenide. We performed ab initio calculations to determine the electronic and phonon band structures of single-layer and bulk WS_2, these results were used to compute the reduced intensity of the 2LA mode from the fourth order Fermi golden rule. Our observations establish an unambiguous and nondestructive Raman fingerprint for identifying single- and few-layered WS_2 islands.

9:36AM A5.00007 Extraordinary room-temperature photoluminescence in WS_2 monolayers[1] , HUMBERTO RODRIGUEZ GUTIERREZ, Department of Physics and Astronomy, University of Louisville, KY, NESTOR PEREA-LÓPEZ, ANA LAURA ELÍAS, AYSE BERKDEMIR, BEI WANG, RUITAO LV, FLORENTINO LÓPEZ-URÍAS, VINCENT CRESPI, HUMBERTO TERRONES, MAURICIO TERRONES, Department of Physics, The Pennsylvania State University, 2-D LAYERED MATERIALS MURI 24 COLLABORATION — Individual monolayers of metal dichalcogenides are atomically thin two-dimensional crystals with attractive physical properties different from their bulk layered counterpart. Here we describe the direct synthesis of WS_2 monolayers with triangular morphologies and strong room-temperature photoluminescence (PL). The Raman response as well as the luminescence as a function of the number of S-W-S layers is also reported. The PL becomes weaker with the increase of S-W-S layers number due to a transition from direct (in a monolayer) to indirect band gap (in multilayers). The edges of WS_2 monolayers exhibit PL signals with extraordinary intensity, around 25 times stronger than the platelets center. The structure and composition of the platelet edges appear to be critical for the PL enhancement effect. These novel 2D nanoscale light sources could find diverse applications including the fabrication of flexible/transparent/low-energy optoelectronic devices

9:48AM A5.00008 How van der Waals Interactions Influence Cohesive Properties of Non-Metallic Solids , GUO-XU ZHANG, ANTHONY M. REILLY, ALEXANDRE TKATCHENKO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany — Standard semilocal and hybrid density functionals are widely used for studying cohesive properties of covalent, metallic, and ionic materials. Only recently it has been recognized that long-range van der Waals (vdW) interactions, that are missing in all semilocal and hybrid functionals, are important for an accurate description of cohesion in solids. Here we construct a database of 64 solids where reference cohesive properties are obtained from a critical revision of the available experimental data. All-electron DFT calculations with explicit treatment of zero-point vibrations for all cohesive properties are performed using the LDA, PBE, and the empirical meta-GGA M06-L [1] functionals. For 23 semiconductors, we carry out PBE and M06-L calculations with the inclusion of screened long-range vdW energy [2]. We find that PBE is the most systematic from the three employed functionals, and its accuracy is improved by a factor of two after the inclusion of vdW interactions. The LDA functional considerably overbinds for all the studied solids. The M06-L functional describes middle-range correlation better for certain semiconductors and ionic crystals, but fails for heavier semiconductors and metals.

10:00AM A5.00009 Analyzing the vdW-DF description of binding mechanisms: Comparison of C60 and benzene adsorption on graphene[1] , KRISTIAN BERLAND, PER HYLDGAARD, Chalmers Universtiy of Technology, MATERIALS PHYSICS AND CARBON ENGINEERING TEAM — There has been several efforts to improve the accuracy of the description of sparse matter problems like molecular adsorption on surfaces using non-local correlation functionals. We have explored the vdW-DF [PRL 92, 246401 (2004)] interaction at different length scales, density regimes, density gradients, and for different system. As test calculations, we compare the potential energy curves of benzene and C60 on graphene and related systems like boron nitride because these reveal the role of geometry and band gap on the functional components. Our analysis is facilitated by explicit control of cutoff parameters in our real-space evaluation of the non-local correlation. We find that vdW-DF is very sensitive to the low density regions, but more so for the original version than in the newer one, vdW-DF2 [PRB 82, 081101 (2010)]. Our results also illustrate that a transferable account of many different geometries requires an accurate account of all length scales involved in the problem. These results are discussed in light of the functional form of vdW-DF. We also show how functional choices greatly affects corrugation. Finally, we examine the role of induced dipoles on the adsorption.

10:12AM A5.00010 Bi-layer excitons in two-dimensional layered materials[1] , MAHESH NEUPANE, GEN YIN, DARSHANA WICKRAMARATNE, ROGER LAKE, University of California, Riverside — Following the prediction of exciton condensation in closely spaced two-dimensional electron-hole bilayer systems [1], there has been a sustained theoretical and experimental investigation of this condensation phase in coupled quantum well material systems. The electron-hole pairs are bound by the interlayer Coulomb interaction, which is tuned by electrostatic gating of the charge density [2]. The magnitude of this interaction is determined by the binding energy between the electron and the hole. Improvements in the exciton binding energy can be achieved by an appropriate choice of materials. The family of van der Walle materials is considered in this study, and the effect of material choice and insulating layer thickness on the excitonic properties will be discussed and compared to experimental investigations using traditional GaAs-AlGaAs coupled quantum wells.

10:24AM A5.00011 Effects of interatomic potentials on mechanical deformation of glasses , WEI-REN CHEN, Oak Ridge National Laboratory, TAKUYA IWASHITA, TAKESHI EGAMI, University of Tennessee — Apparently glasses behave like an elastic solid, which shows a linear relationship between stress and strain in mechanical deformation. However the understanding of the mechanical response of glasses remains elusive because of structural disorder. Mechanical deformation of monatomic model glasses was studied using athermal quasi-static shear (AQS) simulation and with three different potentials. As the interatomic potentials we employed the 12-6 Lennard-Jones (LJ) potential, modified Johnson (mJ) potential, and Dzugutov (Dz) potential, respectively. For mJ and Dz glasses the shear modulus keeps constant below a critical strain, below which it decreases rapidly or discontinuously with strain. Such changes in shear modulus were mostly related to the change in local topology of atomic connectivity or anelasticity. In contrast LJ glass shows a gradual decrease in shear modulus in a continuous manner. The results indicated that the difference arises from the nature of the potentials if the topology of atomic connectivity can be clearly defined.

Session A6 DCMP: Topological Insulators: Novel States in Topological Insulators 302 - Tudor Stanescu, West Virginia University

8:00AM A6.00001 Noncommutative Magneto-Electric Responses of Topological Insulators[1] , BRYAN LEUNG, Rutgers University, EMIL PRODAN, Yeshiva University — Topological magneto-electric response, constructed on a Brillouin torus, defines a Z_2 invariant and classifies topological phases. In the presence of disorder or B field, the notion of Brillouin torus is destroyed. This problem can be overcome by using noncommutative geometry. Starting from a generic 3D lattice model, we derive the magneto-electric response on a noncommutative Brillouin torus. Our result is a noncommutative topological formula. We show that its topological stability requires only mobility gap, therefore the robustness extends to strong disorder regime. Our formula doesn't involve gauge or twisted boundary condition, hence can be computational effective.

8:12AM A6.00002 Heavy Adatoms on Magnetic Surfaces: A Search for Chern Insulators , KEVIN GARRITY, DAVID VANDERBILT, Rutgers University — The theoretical possibility of a quantum anomalous Hall (QAH) insulator, or Chern insulator, has been known for many years, and several strategies for achieving this topological phase have been proposed. However, no unambiguous experimental realization is yet in hand. In this work, we propose a new QAH search strategy and verify its viability with first-principles calculations. We propose constructing a QAH insulator by depositing a layer of adatoms with large spin-orbit coupling (e.g., Pb, Bi) on the surface of a magnetic insulator. We argue that such systems will typically have surface bands with non-zero Chern numbers, so that if metallic, they will typically have a large anomalous Hall conductivity. Thus, the search for Chern insulators reduces to looking for examples exhibiting a global gap across the entire BZ. Using first-principles calculations, we search through many examples of heavy elements on MnTe, MnSe, and EuS surfaces. Our search reveals several Chern insulators with band gaps of up to 0.14 eV, which may be promising targets for future experimental investigations.

8:24AM A6.00003 Topology, Delocalization via Average Symmetry and the Symplectic Anderson Transition , CHARLES KANE, University of Pennsylvania, LIANG FU, Massachusetts Institute of Technology — A field theory of the Anderson transition in two dimensional disordered systems with spin-orbit interactions and time-reversal symmetry is developed, in which localization is driven by the proliferation of vortex-like topological defects. The sign of the vortex fugacity determines the Z_2 topological class of the localized phase. There are two distinct fixed points with the same critical exponents, corresponding to transitions from a metal to an insulator and a topological insulator respectively. The critical conductivity and correlation length exponent of these transitions are computed in a $N = 1 - \epsilon$ expansion in the number of replicas, where for small ϵ the critical points are perturbatively connected to the Kosterlitz Thouless critical point. Delocalized states, which arise at the surface of weak topological insulators and topological crystalline insulators, occur because vortex proliferation is forbidden due to the presence of symmetries that are violated by disorder, but are restored by disorder averaging.

8:36AM A6.00004 Floquet Majorana Fermions for Topological Qubits , D.E. LIU, Duke University, A. LEVCHENKO, Michigan State University, H.U. BARANGER, Duke University — We develop an approach to realizing a topological phase transition and non-Abelian statistics with dynamically induced Floquet Majorana Fermions (FMFs). When the periodic driving potential does not break fermion parity conservation, FMFs can encode quantum information. Quasi-energy analysis shows that a stable FMF zero mode and two other satellite modes exist in a wide parameter space with large quasi-energy gaps, which prevents transitions to other Floquet states under adiabatic driving. We also show that in the asymptotic limit FMFs preserve non-Abelian statistics and, thus, behave like their equilibrium counterparts.

8:48AM A6.00005 ABSTRACT WITHDRAWN –

9:00AM A6.00006 Emergent Supersymmetry in Topological Superconductors , TARUN GROVER, Kavli Institute for Theoretical Physics, DONNA SHENG, Cal State University Northridge , ASHVIN VISHWANATH, University of California Berkeley — In the absence of interactions, topological superconductors (TSC) host helical Majorana fermion edge states protected by time reversal symmetry. Increasing interactions can lead to spontaneous magnetic order at the boundary. We show that the associated quantum phase transition, if continuous, has emergent space-time supersymmetry at low energies. The magnetic order parameter field is identified as the superpartner of the Majorana fermions. These results are obtained using field theoretical arguments and are verified by numerical DMRG solution of a lattice model that mimics the physics of the phase transition. The emergent supersymmetry, accessed by tuning a single parameter, has striking consequences such as an exact relation between the correlation functions of fermions and those of the order parameter. Similar results are argued to hold for the 2+1 dimensional boundary of a bulk topological superconductor. Generalization to topological insulator surfaces will be mentioned.

9:12AM A6.00007 Dynamical manipulation of 2D topological insulator edge states for Majorana fermion braiding[1] , SHU-PING LEE, JASON ALICEA, caltech — Edge states of 2D topological insulators such as HgTe provide a promising platform for realizing Majorana modes. Networks required for braiding Majoranas along the edge channels can be obtained by adjoining HgTe quantum wells to form corner junctions. Physically cutting quantum wells for this purpose, however, presents technical challenges. Here we propose a more accessible means of forming networks that relies on dynamically manipulating the location of edge states inside of a *single* HgTe sheet. In particular, we show that edge states can effectively be dragged into the system's interior by gating a region near the edge into a metallic regime and then removing the resulting gapless carriers via proximity-induced superconductivity. This method allows one to construct rather general quasi-1D networks along which Majorana modes can be shuttled and exchanged by electrostatic means.

9:24AM A6.00008 Topological Excitonic Superfluids in Three Dimensions[1] , MATTHEW GILBERT, University of Illinois - Urbana-Champaign, EWELINA HANKIEWICZ, Universitaet Wuerzburg, YOUNGSEOK KIM, University of Illinois - Urbana-Champaign — We study the equilibrium and non-equilibrium properties of topological dipolar intersurface exciton condensates within time-reversal invariant topological insulators in three spatial dimensions without a magnetic field. We elucidate that, in order to correctly identify the proper pairing symmetry within the condensate order parameter, the full three-dimensional Hamiltonian must be considered. As a corollary, we demonstrate that only particles with similar chirality play a significant role in condensate formation. Furthermore, we find that the intersurface exciton condensation is not suppressed by the interconnection of surfaces in three-dimensional topological insulators as the intersurface polarizability vanishes in the condensed phase. This eliminates the surface current flow leaving only intersurface current flow through the bulk. We conclude by illustrating how the excitonic superfluidity may be identified through an examination of the terminal currents above and below the condensate critical current.

9:36AM A6.00009 Quantum interference and quantum oscillation on the surface of mirror symmetric topological insulators[1] , CHEN FANG, University of Illinois at Urbana Champaign, ARIS ALEXANDRADINATA, Princeton University, MATTHEW GILBERT, University of Illinois at Urbana Champaign, SU-YANG XU, ZAHID HASAN, ANDREI BERNEVIG, Princeton University — We first study the quasiparticle interference (QPI) of the surface states in crystalline topological insulators which possess mirror symmetry and time-reversal symmetry, by analyzing the Fourier transformed local density of states (FT-LDOS), $\rho(bq,\omega)$ around a single static impurity on the surface. The topological characters of the surface states of these new materials lead to QPI patterns distinct from those of 2D metals and of surface states on 3D time-reversal TI's. We apply the general analysis to the QPI on the $\langle 001\rangle$-surface of $Pb_{1-x}Sn_xTe$ and predict all vanishing singularities in $\rho(bq,\omega)$. We also demonstrate that QPI can also be used to probe the Lifshitz transition of the surface states observed in recent ARPES experiment. We next study the Shubnikov de Hass oscillation of these surface states and show that the oscillation has a single period before the Lifshitz transition and two distinct periods after the transition. Adding in-plane magnetic field before the Lifshitz transition leads to splitting of the period into two close periods and a beating thereof.

9:48AM A6.00010 Chern and Majorana Modes in QuasiCrystals , INDUBALA SATIJA, George Mason University, GERARDO NAUMIS, Universidad Nacional Autonoma de Mexico — The topology of quasicrystals is found to have a novel manifestation in the spatial profile of band edge states as topological invariants transform peaks into doublets of size equals the Chern number. The Chern-dressed peaks form a self-similar pattern encoding topological fingerprints at all length scales. For quasicrystals exhibiting localized states, fluctuations about exponentially localized zero modes describe the onset to topological transition where Majorana modes delocalize. These exotic modes can be captured in their entirety using $U(1)$ symmetry breaking perturbation that supports both the Chern and the Majorana modes. Here topological transition is accompanied by localization as edge-localized modes move to the interior, loosing topological protection.

10:00AM A6.00011 Vortex zero modes, chiral anomaly and effective field theory for odd parity topological superconductor in three dimensional Dirac materials[1] , BITAN ROY, PALLAB GOSWAMI, National High Magnetic Field Laboratory — The low energy quasiparticle dispersion of various narrow gap and gapless semiconductors are respectively described by three dimensional massive and massless Dirac fermions. The three dimensional Dirac spinor structure admits an interesting time-reversal invariant, odd parity and Lorentz pseudo-scalar topological superconducting state. In this talk we demonstrate the existence of fermion zero energy states in the vortex core of this odd parity topological superconductor under generic conditions. Guided by the existence of the zero modes and its intimate connection with the chiral anomaly and the index theorem, we derive an effective topological field theory for such a superconducting state. We also discuss the experimental consequences of the zero modes and the topological field theory for the low temperature unconventional superconducting states of copper intercalated bismuth selenide, and indium doped tin telluride.

[1]NSF

10:12AM A6.00012 Ab initio study of topological insulating property in the heterojunction of Bi (111) bilayer and Bi_2Te_2Se , KYUNG-HWAN JIN, SEUNG-HOON JHI, Department of Physics, POSTECH — Study of topological insulator (TI) is showing rapid progress in both theory and experiment, particularly on three dimensional materials. Examples of two dimensional TI (quantum spin Hall) materials are, on the other hand, comparatively less common. As such, theoretical predictions of single Bi (111) bilayers as TI draw great attention from experiment. A recent report of ARPES measurements claims verification of the 2D TI property of Bi bilayer, but analysis leaves much room for further clarification. Because Bi (111) bilayers grown on 3D TI substrates such as Bi_2Te_3 and Bi_2Te_2Se; understanding the details of the interface between the Bi bilayer and 3D TI substrates is essentially required. We study the electronic structures of Bi bilayer-Bi_2Te_2Se heterojunction from first-principles calculations. We find a substantial shift of Dirac cone from the TI substrates into Bi bilayer that thus becomes metallic on TI substrates. It is shown that the origin of this change is the inversion-symmetry breaking in Bi bilayer due to TI substrate. By comparing our calculations of Bi bilayer nanoribbons on Bi_2Te_2Se with STM/STS measurements, we successfully resolve and locate the edge states of a single Bi bilayer and confirm its 2D TI character.

10:24AM A6.00013 Topological indices, defects, and Majorana fermions in chiral superconductors , DAICHI ASAHI, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo — We study theoretically the role of topological invariants to protect the Majorana fermions in a model of two-dimensional (2D) chiral superconductors which belong to class D of the topological periodic table. A rich phase diagram is revealed. Each phase is characterized by the topological invariants for 2D (Z) and 1D (Z2), which lead to the Majorana fermion at the edge dislocation and the core of the vortex. The topological invariants are determined by the hopping integrals along x and y directions. Interference of the Majorana fermions originating from the different topological invariants is studied. The interaction between zero-energy states at edge dislocations and at vortex cores eliminates the zero-energy states when they coexist at the same position. The stability of the Majorana fermion with respect to the interlayer coupling, i.e., in 3D, is also examined. We found that the zero-energy state survive a finite hopping integral along the z-direction unless the energy gap closes.

10:36AM A6.00014 On the possibility of the fractional ac Josephson effect and doubled Shapiro steps in non-topological Josephson junctions[1] , JAY SAU, Harvard University, EREZ BERG, Weizmann Institute of science, BERTRAND HALPERIN, Harvard University — Topological superconductors supporting Majorana Fermions with non-abelian statistics are presently a subject of intense theoretical and experimental effort. It has been proposed that the observation of a half-frequency or a fractional Josephson effect is a more reliable test for topological superconductivity than the search for end zero modes. In fact, the fractional Josephson effect has been observed for the semiconductor nanowire system in the form of doubled Shapiro states. Here we consider the possibility of seeing such a fractional ac Josephson and doubled Shapiro steps from a superconducting nanowire in the non-topological phase. Using a semiclassical treatment we find that both the fractional ac Josephson effect and the doubled Shapiro step can, in principle, occur in the non-topological phase because of non-dynamical Landau Zener processes associated with the Andreev bound state spectrum of the junction. Therefore, while the observation of doubled Shapiro steps can be taken as indicative of a topological phase, it may not be a smoking gun signature for topological superconductivity and Majorana fermions.

10:48AM A6.00015 Majorana Flat Bands and Uni-directional Majorana Edge States in Gapless Topological Superconductors[1] , KAM TUEN LAW, CHRIS L.M. WONG, JIE LIU, Hong Kong University of Science and Technology, PATRICK A. LEE, Massachusetts Institute of Technology — In this work, we show that an in-plane magnetic field can drive a fully gapped $p \pm ip$ topological superconductor into a gapless phase which supports Majorana flat bands (MFBs). Unlike previous examples, the MFBs in the gapless regime are protected from disorder by a chiral symmetry. In addition, novel uni-directional Majorana edge states (MESs) which propagate in the same direction on opposite edges appear when the chiral symmetry is broken by Rashba terms. Unlike the usual chiral or helical edge states, uni-directional MESs appear only in systems with a gapless bulk. We show that the MFBs and the uni-directional MESs induce nearly quantized zero bias conductance in tunneling experiments.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A7 DMP: Focus Session: Graphene Devices I 303 - K.C. Fong, Caltech

8:00AM A7.00001 Graphene-based Hall Sensors for direct magnetic imaging by using Scanning Hall Probe Microscope , SELDA SONUSEN, Sabanci University, SEDA AKSOY, Istanbul Technical University, MUNIR DEDE, Nanomagnetics Inst., AHMET ORAL, Sabanci University — Graphene has been attracting great interest due to its unique electronic and mechanical properties for both fundamental and experimental studies since 2004. Graphene is a promising material for many applications in high speed electronic and spintronic devices as well as sensors. Its high mobility makes graphene a good candidate for magnetic imaging in Scanning Hall Probe Microscope (SHPM). Hall probes are used to scan the magnetic samples to image magnetic domains in SHPM. In this work, single layer graphene produced by chemical vapor deposition technique is used to fabricate Hall sensors by optical and the e-beam lithography with sizes from 500 nm to a few micrometers. The Hall crosses are characterized by Raman mapping to make sure that they are made of a single layer graphene. The Graphene Hall Sensors noise spectra is measured as a function of different bias currents and carrier concentrations at 300 K, 77 K and 4.24K. The imaging performance of the Hall sensor will be demonstrated at different temperatures by imaging a garnet crystal using a Low Temperature Scanning Hall Probe Microscope (LT-SHPM).

8:12AM A7.00002 Molecular Dynamics Studies of Graphene Nanobubbles , ZENAN QI, HAROLD PARK, Boston University, VITOR M. PEREIRA, National University of Singapore, ANTONIO H. CASTRO-NETO, National University of Singapore and Boston University, DAVID K. CAMPBELL, Boston University — We apply classical molecular dynamics to study pressure-induced deformations and the resulting pseudomagnetic (PSM) fields for monolayer graphene nanobubbles (NBs) of various geometries. We obtain the PSM field distributions for triangular, square, rectangular, hexagonal, and circular graphene NBs and find that in most cases the PSM fields near the tops of the NBs are smaller than around the NB edges. For circular NBs of diameter smaller than about 2nm, we find that the PSM field contribution from bending and curvature becomes comparable to from the traditional in-plane component of the gauge field.

8:24AM A7.00003 Spatial manipulation of massless Dirac fermions in ballistic graphene devices , PIRANAVAN KUMARAVADIVEL, XU DU, Department of Physics and Astronomy, Stony Brook University — Pseudo-spin conservation of the chiral quasi-particles in graphene, governed by the Dirac-Weyl equation, has resulted in interesting study of transport phenomena such as their selective transmission across potential barriers. Utilizing these properties to spatially manipulate the electrons in graphene devices require ballistic samples with well-defined, sharp junctions. We report our current work on the fabrication and characterization of such ballistic devices that will enable us to guide and control electron flow in 2D.

8:36AM A7.00004 Graphene as an etch mask for silicon , ANIRUDDH RANGARAJAN, JOSHUA WOOD, JUSTIN KOEPKE, JOSEPH LYDING, University of Illinois at Urbana-Champaign — We are using graphene as a hard etch mask for silicon. The error introduced by its edges is hypothesized to be far less compared to innate issues of photolithography (e.g. undercut, sidewall hardening). This presents the possibility of making a highly precise etch mask. We lithographically pattern a graphene layer transferred to a Si(100) surface and fluorinate the sample to demonstrate the selective etching on exposed regions. The graphene layer becomes fluorinated, but shields the silicon underneath. The Si(100) with selective graphene coating was subjected to isotropic etching by xenon difluoride (at 1.0 Torr, and N_2 at 35.0 Torr) for 180 s to remove approximately 190 nm of silicon. Raman spectroscopy confirms the onset of sp^3 hybridization of carbon atoms in the hexagonal lattice, brought on by covalent C–F bonding. Along with the possibility of producing highly precise silicon structures, the monolayer mask has added advantages, such as not requiring as many processing steps as the conventional method involving photoresist.

8:48AM A7.00005 Low-Damage Sputter Deposition on Graphene , CHING-TZU CHEN, IBM Thomas J Watson Research Center, EMANUELE CASU, IBM Thomas J Watson Research Center, Politecnico di Torino, MARCIN GAJEK, SIMONE RAOUX, IBM Thomas J Watson Research Center — Despite its versatility and prevalence in the microelectronics industry, sputter deposition has seen very limited applications for graphene-based electronics. We have systematically investigated the sputtering induced graphene defects and identified the reflected high-energy neutrals of the sputtering gas as the primary cause of damage. In this talk, we introduce a novel sputtering technique that is shown to dramatically reduce bombardment of the fast neutrals and improve the structural integrity of the underlying graphene layer. We also demonstrate that sputter deposition and in-situ oxidation of 1 nm Al film at elevated temperatures yields homogeneous, fully covered oxide films with r.m.s. roughness much less than 1 monolayer, which shows the potential of using such technique for gate oxides, tunnel barriers, and multilayer fabrication in a wide range of graphene devices.

9:00AM A7.00006 Enhanced Breakdown Reliability and Spatial Uniformity of Atomic Layer Deposited High-k Gate Dielectrics on Graphene via Organic Seeding Layers , VINOD SANGWAN, DEEP JARIWALA, STEPHEN FILIPPONE, HUNTER KARMEL, JAMES JOHNS, JUSTICE ALABOSON, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, TOBIN MARKS, Department of Chemistry and Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, LINCOLN LAUHON, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, MARK HERSAM, Department of Materials Science and Engineering, Chemistry and Medicine, Northwestern University, Evanston, Illinois 60208 — Ultra-thin high-κ top-gate dielectrics are essential for high-speed graphene-based nanoelectronic circuits. Motivated by the need for high reliability and spatial uniformity, we report here the first statistical analysis of the breakdown characteristics of dielectrics grown on graphene. Based on these measurements, a rational approach is devised that simultaneously optimizes the gate capacitance and the key parameters of large-area uniformity and dielectric strength. In particular, vertically heterogeneous oxide stacks grown *via* atomic-layer deposition (ALD) seeded by a molecularly thin perylene-3,4,9,10-tetracarboxylic dianhydride (PTCDA) organic monolayer result in improved reliability (Weibull shape parameter $\beta > 25$) compared to the control dielectric directly grown on graphene without PTCDA ($\beta < 1$). The optimized sample also showed a large breakdown strength (Weibull scale parameter, $E_{BD} > 7$ MV/cm) that is comparable to that of the control dielectric grown on Si substrates.

9:12AM A7.00007 Gate-defined Quantum Confinement in Suspended Bilayer Graphene , MONICA ALLEN, Harvard University — Quantum confined devices in carbon-based materials offer unique possibilities for applications ranging from quantum computation to sensing. In particular, nanostructured carbon is a promising candidate for spin-based quantum computation due to the ability to suppress hyperfine coupling to nuclear spins, a dominant source of spin decoherence. Yet graphene lacks an intrinsic bandgap, which poses a serious challenge for the creation of such devices. We present a novel approach to quantum confinement utilizing tunnel barriers defined by local electric fields that break sublattice symmetry in suspended bilayer graphene. This technique electrostatically confines charges via band structure control, thereby eliminating the edge and substrate disorder that hinders on-chip etched nanostructures to date. We report clean single electron tunneling through gate-defined quantum dots in two regimes: at zero magnetic field using the energy gap induced by a perpendicular electric field and at finite magnetic fields using Landau level confinement. The observed Coulomb blockade periodicity agrees with electrostatic simulations based on local top-gate geometry, a direct demonstration of local control over the band structure of graphene. This technology integrates quantum confinement with pristine device quality and access to vibrational modes, enabling wide applications from electromechanical sensors to quantum bits. More broadly, the ability to externally tailor the graphene bandgap over nanometer scales opens a new unexplored avenue for creating quantum devices.

9:48AM A7.00008 Band gap estimation in bilayer graphene through quantum capacitance measurement , KOSUKE NAGASHIO, TOMONORI NISHIMURA, AKIRA TORIUMI, University of Tokyo — The estimation of the quantum capacitance (C_Q) through the capacitance measurement provides the direct information on Density of states (DOS) in graphene since the energy cost to induce carriers is introduced as $C_Q = e^2 DOS$ in series with the geometrical capacitance (C_{ox}) in the equivalent circuit ($1/C \quad = 1/C_{ox} \quad + 1/C_Q$). For bilayer graphene with Y_2O_3 topgate structure, the band gap opening was qualitatively observed in DOS - energy relation estimated from C_Q under the large displacement. The band gap determined by C_Q was larger than the transport gap determined by variable-range hopping in gap states on IV measurement since carriers which respond to the alternating voltage are not required to transport throughout the device.

10:00AM A7.00009 Local Spectroscopy of the Electrically Tunable Band Gap in Trilayer Graphene , MATTHEW YANKOWITZ, University of Arizona, FENGLIN WANG, CHUN NING LAU, University of California, Riverside, BRIAN LEROY, University of Arizona — Trilayer graphene exhibits two natural stacking orders (Bernal and rhombohedral), and the electronic properties differ substantially between the two. While Bernal-stacked trilayer graphene is a semimetal with an electrically tunable band overlap, rhombohedrally stacked trilayer graphene has an electrically tunable band gap. We have performed low-temperature ultra-high vacuum STM measurements of both stacking orders. In Bernal-stacked trilayer graphene, we observe metallic behavior for all energies and electric fields probed. In rhombohedrally stacked trilayer graphene, we measure an electric field tunable band gap whose magnitude is well described by theoretical predictions. Furthermore, we explore the microscopic nature of the band gap by probing spatial variations throughout the sample.

10:12AM A7.00010 Dual-dated suspended double-layer graphene devices , FENGLIN WANG, JHAO-WUN HUANG, YONGJIN LEE, LEI JING, KEVIN MYHRO, Department of Physics and Astronomy, University of California, Riverside, JAIRO VELASCO JR., University of California, Berkeley, HANG ZHANG, CHUNNING LAU, Department of Physics and Astronomy, University of California, Riverside — Using a transfer technique, we are able to align two graphene sheets together and fabricate a dual-gated suspended double-layer system via a delicate multi-step fabrication process. This experimental system includes variety of parameters, which provides potential for the discovery of new physics, such as the coupling and decoupling between two graphene sheets. We will present and discuss latest experimental results.

10:24AM A7.00011 Electron-state engineering of bilayer graphene by sandwiching ionic molecules[1] , NGUYEN THANH CUONG, MINORU OTANI, NRI-AIST, Tsukuba, Japan, SUSUMU OKADA, University of Tsukuba, Japan — Graphene has stimulated intense interest not only in the field of the low-dimensional sciences but also in the electronic device engineering because of its unique structural and electronic properties. In particular, they are regarded as a candidate material for the next-generation semiconductor devices. However, graphene is a metal with a pair of liner dispersion bands at the Fermi level, so that they are not utilized for the logic circuit. Therefore, it is important to tune the electronic structure and to get a semiconducting graphene. In this work, we demonstrate the possibility of controlling the band-gap and carrier type of bilayer graphene by using ionic molecules based on the first-principles total-energy calculations. Our calculations suggest that bilayer graphene sandwiched by a pair of cation and anion molecules is a semiconductor with a moderate energy gap of 0.26 eV that is attributable to the strong local dipole field induced by the ionic molecules. Furthermore, we also show that the carrier type of semiconducting bilayer graphene is controllable,i.e. intrinsic, p-type, or n-type semiconductors, by tuning anion-cation pair. [1].

10:36AM A7.00012 Towards *in situ* correlation of atomic structure and device functionality in graphene-based devices , S. M. HOLLEN, NANCY SANTAGATA, JUSTIN YOUNG, JAY GUPTA, EZEKIEL JOHNSTON-HALPERIN, Ohio State University, CENTER FOR EMERGENT MATERIALS TEAM — The use of scanned probe microscopy to study atomic-scale phenomena is well established; however, there is a gap in our understanding of how atomistic studies connect to macroscopic measurements such as electron and spin transport. This gap is of particular importance to 2D materials such as graphene, germanane and MoS_2 due to the extreme sensitivity to defects, adatoms, and local electronic inhomogeneities. We present work towards the integration of low temperature scanning tunneling microscopy (STM) with *in situ* transport measurements on nanoscale graphene devices in ultrahigh vacuum. Challenges we are addressing include (i) fabricating devices small enough that a sufficient fraction of the surface can be modified within the small scan range typical of STM, (ii) design of alignment electrodes for locating the devices with STM, and (iii) modification of the STM hardware to integrate electron transport measurements. We anticipate that being able to correlate device transport measurements with atomic scale characterization and modification of the graphene surface will allow us to address the importance of the local environment to device functionality.

10:48AM A7.00013 In-situ Fabrication and Electronic Characterization of Junction-confined Single Layer Graphene Nanoribbons[1] , ZHENGQING JOHN QI, JULIO RODRIGUEZ-MANZO, University of Pennsylvania, SUNG JU HONG, Seoul National University, MARIJA DRNDIC, A.T. CHARLIE JOHNSON, University of Pennsylvania — We report electronic measurements on high quality single layer junction-confined graphene nanoribbons fabricated in a transmission electron microscope (TEM). In this work, a process is demonstrated for the fabrication and confirmation of pristine single layer graphene nanoribbons using high vacuum current annealing and precision nano-sculpting, both conducted within the vacuum chamber of a TEM. Briefly, CVD-grown graphene is patterned into a freely-suspended nanoribbon connected to large area contacts. The sample is then mounted on a TEM holder with electrical feedthroughs to allow for simultaneous imaging and in-situ electrical transport measurements within the TEM. A focused electron beam is used to progressively narrow the ribbon, providing a platform to controllably sculpt and define the device geometry while characterizing its electrical properties. In-situ electrical measurements and TEM imaging with sub-nm resolution revealed the dependence of the nanoribbon resistance as a function of width in the range 17 – 280 nm. Monolayer graphene were found to sustain current densities in excess of 5 x 10^9 A/cm^2, orders of magnitude higher than copper while the conductance varied approximately as $w^{0.75}$, where w is the ribbon width in nanometers. These results demonstrates graphene's potential as a next generation, high performance interconnects material with the ability to reach single-digit technology nodes at the level of a single atomic layer.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A8 DCMP: Graphene: Quantum Hall Effect 307 - Herb Fertig, Indiana University

8:00AM A8.00001 Four-flux fractional quantum Hall states in suspended graphene , ANDREI LEVIN, BENJAMIN FELDMAN, Harvard University, BENJAMIN KRAUSS, JURGEN SMET, Max-Planck-Institut fur Festkorperforschung, AMIR YACOBY, Harvard University — The interactions between charge carriers in ultra-clean graphene subject to a perpendicular magnetic field can drive the system to condense into one of a set of incompressible fractional quantum Hall (FQH) states. We use a scanning single-electron transistor to measure the local electronic compressibility of suspended graphene. In addition to observing incompressible behavior at fractional filling factors in the two-flux composite fermion sequence, we also observe FQH states arising from four-flux composite fermions, including states at filling factors $\nu = 1/5$, 2/7, 2/9, 3/11, 5/7 and 6/5. We measure the energy gaps of these states as a function of magnetic field; most display approximately linear scaling. Interestingly, several four-flux FQH states are conspicuously absent near filling factors $\nu = 1$ and 2, despite the robust appearance of their counterparts near $\nu = 0$.

8:12AM A8.00002 Measurements of Chiral Heat Current in Graphene in the Quantum Hall Regime , SEUNG-GEOL NAM, Department of Physics, Pohang University of Science and Technology, Korea, E.H. HWANG, SKKU Advanced Institute of Nanotechnology, Sungkyunkwan University, Suwon, Korea, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, Korea — Heat transport measurements can offer a new window to probe the low-energy physics in quantum-Hall systems, which cannot be provided by the electronic transport measurements. In this presentation, we report chiral heat transport measurements in monolayer graphene in the integer quantum Hall regime. We inject charge carriers at a higher temperature than the system bulk and measure the thermoelectric voltage corresponding to the local electron temperature at a distance from the injection point. We find that in graphene heat transport at the edge in the quantum Hall regime is chiral and its direction is dependent on both the carrier type and the magnetic field direction. Measured thermoelectric signals in unipolar regions can be understood by the Mott relation, but a severe deviation of the signals from the Mott relation is found at a p-n junction. Thermoelectric signal decays with distance from the heater and saturates with increasing heating power even though it increases linearly at low powers, which indicates that a part of heat is transferred out of the edge current.

8:24AM A8.00003 Drude weight, cyclotron resonance, and the Dicke model of graphene cavity QED[1] , MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, LUCA CHIROLLI, VITTORIO GIOVANNETTI, NEST, Scuola Normale Superiore and Istituto Nanoscienze-CNR, ALLAN MACDONALD, Department of Physics, University of Texas at Austin, Austin, Texas 78712, USA — The unique optoelectronic properties of graphene make this two-dimensional (2D) material an ideal platform for fundamental studies of cavity quantum electrodynamics (QED) in the strong-coupling regime. The celebrated Dicke model of cavity QED can be approximately realized in this material when the cyclotron transition of its 2D massless Dirac fermion carriers is nearly resonant with a cavity photon mode. In this talk I will discuss the theory of strong matter-photon coupling in this circumstance, emphasizing the essential role of a dynamically generated matter energy term that is quadratic in the photon field and absent in graphene's low-energy Dirac model.

8:36AM A8.00004 Theory of unconventional quantum Hall effect in strained graphene[1] , ZI-XIANG HU, ChongQing University, China and Princeton University, USA, BITAN ROY, KUN YANG, National High Magnetic Field Laboratory, Florida State University, USA — We show graphene discerns an unconventional sequence of quantized Hall conductivity, when subject to both magnetic fields (B) and strain through both theoretical arguments and numerical calculations. The strain produces time-reversal symmetric pseudo/axial magnetic fields (b). The single electron spectrum is composed of two inter-penetrating sets of Landau levels (LLs), located at $\pm\sqrt{2n|b \pm B|}$, n = 0, 1, 2,.... For $b > B$, these two sets of LLs have opposite chiralities, resulting in oscillating Hall conductivity between 0 and $\mp 2e^2/h$ in electron and hole doped system, respectively, as the chemical potential deviates from the neutrality point, but remains in its vicinity. The electron electron interactions stabilizes various correlated ground states, e.g., spin-polarized, quantum spin-Hall insulators at and near the neutrality point, and possibly anomalous Hall insulating phase at incommensurate filling. Such broken symmetry ground states have similarities as well as significant differences from there counterparts in the absence of strain. For realistic strength of magnetic fields and interactions, we present scaling of interaction induced gap for various Hall states within the zeroth Landau level.

8:48AM A8.00005 Valley-kink in Bilayer Graphene at ν =0: A Charge Density Signature for Quantum Hall Ferromagnetism[1] , CHIA-WEI HUANG, EFRAT SHIMSHONI, Department of Physics, Bar-Ilan University, Ramat Gan, 52900, Israel, HERBERT FERTIG, Department of Physics, Indiana University, Bloomington, IN 47405, USA — We investigate the interaction-induced valley textured domain walls in bilayer graphene at the ν =0 quantum Hall state, subject to a kink-like perpendicular electric field. Such a state can be realized in a double-gated suspended sample, where the electric field changes sign across a line in the middle of the sample. Using the Hartree-Fock approximation, we find that the Coulomb interaction opens a gap between the two lowest-lying states near the Fermi level, and yields a smooth valley texture throughout the domain walls. Moreover, our results suggest possibilities to visualize the resulting texture via measuring the charge density difference between the two graphene layers, which is predicted to exhibit a charge density wave. The width of the smooth texture and the resulting pattern can be tuned by the interplay between the magnetic field and gate electric fields.

[1]We thank financial support from the US-Israel Binational Science Foundation (BSF)

9:00AM A8.00006 Cyclotron-resonance-induced photovoltaic effect in high-mobility graphene in the quantum Hall regime , SATORU MASUBUCHI, MASAHIRO ONUKI, MIHO ARAI, Institute of Industrial Science, University of Tokyo, Japan, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, Japan, TOMOKI MACHIDA, Institute of Industrial Science, University of Tokyo, Japan — We have investigated the infrared photoinduced voltage ΔV in high-mobility graphene on hexagonal boron nitride in the quantum Hall regime. We observed ΔV of up to several μV at $\nu = \pm 2$ quantum Hall states under the cyclotron resonance conditions. The dependence of ΔV on the bias current indicates that ΔV signals derive from the photovoltaic effect rather than the bolometric effect. The dependence of ΔV on magnetic field direction and measurement geometry suggest the edge channel transport as an origin of photovoltaic effect. ΔV signals were robust up to $T = 180$ K, indicating that ΔV signals can be used for developing novel terahertz photodetectors operating at high temperatures.

9:12AM A8.00007 Landau-level mixing in the fractional quantum Hall effect in graphene[1] , MICHAEL PETERSON, California State University Long Beach, CHETAN NAYAK, Microsoft Research, University of California Santa Barbara — We study the effects of Landau level mixing on the fractional quantum Hall effect in graphene. Landau level mixing in graphene is especially important since the ratio of the Coulomb energy to the cyclotron energy is independent of magnetic field and of order one. In particular, we derive an effective Hamiltonian that fully incorporates Landau level mixing by renormalizing the two-body Coulomb potential (renormalizing the Haldane pseudopotentials) and inducing particle-hole symmetry breaking three-body terms, cf. Bishara and Nayak, Phys. Rev. B 80, 121302(R) (2009). As opposed to the FQHE in GaAs semiconductor devices, graphene has no finite-thickness corrections since the two-dimensional graphene sheet is atomically thin and the Dirac nature of the electrons in graphene forces the particle-hole symmetry breaking three-body terms to exactly vanish in the lowest Landau level.

[1]We acknowledge support from DARPA, Microsoft Station Q, and Cal State Long Beach Start-up.

9:24AM A8.00008 Self-similar occurrence of massless Dirac particles in graphene under magnetic field , JUN-WON RHIM, KWON PARK, Korea Institute for Advanced Study — Intricate interplay between the periodicity of the lattice structure and that of the cyclotron motion gives rise to a well-known self-similar fractal structure of the Hofstadter butterfly for an electron moving in lattice under magnetic field. Evolving from the $n = 0$ Landau level, the central band of the Hofstadter butterfly is especially interesting since it may hold a key to the mysteries of the fractional quantum Hall effect in graphene. In this paper, we develop an effective Hamiltonian method that can be used to provide an accurate analytic description of the central Hofstadter band in the weak-field regime. One of the most important discoveries obtained in this work is that massless Dirac particles always exist inside the central Hofstadter band no matter how small the magnetic flux may become. In other words, with its bandwidth broadened by the lattice effect, the $n = 0$ Landau level contains massless Dirac particles within itself. In fact, by carefully analyzing the self-similar recursive pattern of the central Hofstadter band, we conclude that massless Dirac particles should occur under arbitrary magnetic field. As a corollary, the central Hofstadter band also contains a self-similar structure of recursive Landau levels associated with such massless Dirac particles.

9:36AM A8.00009 Observation of the Hofstadter butterfly in graphene on boron nitride , PATRICK MAHER, CORY DEAN, CARLOS FORSYTHE, LEI WANG, FERESHTE GHAHARI, Columbia University, PILKYUNG MOON, MIKITO KOSHINO, Tohoku University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, KEN SHEPARD, JAMES HONE, PHILIP KIM, Columbia University — In 1976, Douglas Hofstadter considered the general problem of 2D electrons subject to both a magnetic field and a periodic potential. His solution predicted a remarkably complex energy spectrum exhibiting self-similar fractal structure, termed the Hofstadter Butterfly. Experimental exploration of this problem has been limited by the difficulty of fabricating a system with a lattice constant on the order of the magnetic length. It has recently been shown that single layer graphene on hexagonal-BN develops a Moiré pattern with a length of up to 15 nm when the rotational angle between the two lattices approaches zero. We present data demonstrating that for bilayer graphene on hexagonal boron nitride, the effect of the modulation potential associated with the Moiré pattern is large enough to be observable by standard transport. Under large magnetic fields, additional gaps appear within the usual bilayer quantum Hall spectrum, consistent with calculations of the Hofstadter spectrum. We present the first direct experimental evidence of the longstanding theoretical prediction that the gaps arising from the superlattice are characterized by two integer quantum numbers.

9:48AM A8.00010 Symmetry Breaking in Hofstadter's Butterfly in graphene[1] , CARLOS FORSYTHE, Department of Physics, Columbia University, CORY DEAN, LEI WANG, Department of Mechanical Engineering, Columbia University, PATRICK MAHER, FERESHTE GHAHARI, Department of Physics, Columbia University, PILKYUNG MOON, MIKITO KOSHINO, Department of Physics, Tohoku University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, KEN SHEPARD, Department of Electrical Engineering, Columbia University, JIM HONE, Department of Mechanical Engineering, Columbia University, PHILIP KIM, Department of Physics, Columbia University — We will present magnetotransport measurements in hBN encapsulated bilayer graphene devices where one of hBN substrates provides a weak modulation of lattice potential. Under a strong magnetic field, interplay between periodic electric potential and quantizing magnetic field lead to a fractal energy spectrum known as Hofstadter's butterfly. In graphene, while spin and layer symmetry breakings are expected in dual gated devices under large magnetic fields, valley symmetry breaking in the Hofstadter regime is not so easily understood. We will present the observance of these measured gaps along with a discussion of symmetry breaking in our BLG-hBN devices. Further quantitative analysis of these breakings will be presented through the temperature dependence of quantized conductance at these gaps. Through careful modulation of temperature and electron density, we have extracted a range of activation energies associated with symmetry breakings.

10:00AM A8.00011 Andreev Reflections and Superconducting Proximity Effect in lateral BN/Graphene/$NbSe_2$ Heterostructures in the Integer Quantum Hall Regime , DMITRI K. EFETOV, CLEVIN HANDSCHIN, CORY DEAN, LEI WANG, PHILIP KIM, Columbia University, KIM GROUP TEAM — Inducing Superconductivity (SC) via proximity effect into the topological edge states of a 2D conductor in the Quantum Hall Regime (QHE) has been a long standing proposition which has recently reinvigorated attention. Here the combination of SC and QHE has a wide range of predictions such as the appearance of additional edge-states in the integer QHE. With the recent development of high mobility graphene on h-BN with an extremely low onset of the QHE (0.5T) and its high compatibility with various superconductors the road to test these predictions is now open. In this study we present lateral magneto-transport and electronic spectroscopy measurements of BN/graphene/NbSe2 heterostructures. We find that the NbSe2/graphene superconductor-normal metal interface (SN) has a very high transparency with extremely low electrical resistances of R$\sim$100Ohm and gives rise to Andreev reflections and a strong SC proximity effect in graphene below the critical SC transition temperature Tc $\sim$ 7.2K. The high mobility of the graphene on h-BN and the relatively high SC upper critical magnetic field of NbSe2 Hc2 $\sim$ 5T allow for a wide magnetic field range of 1-5T in which the SC and the QHE coexist.

10:12AM A8.00012 Edge magnetoplasmons in graphene: determination of carrier drift velocity in Quantum Hall regime[1] , IVANA PETKOVIC, F.I.B. WILLIAMS, KEYAN BENNACEUR, FABIEN PORTIER, PATRICE ROCHE, D.C. GLATTLI, Service de Physique de l'Etat Condense/IRAMIS/DSM (CNRS URA 2464), CEA Saclay, F-91191 Gif-sur-Yvette — Edge Magneto-Plasmons (EMP) are gapless quasi 1D elementary excitations which are split off from the bulk magneto-plasmon modes by the sample boundary, and are a tool of choice to investigate the structure of the edge of a 2D electron gas. We give a first experimental demonstration of their presence in graphene in the quantum Hall regime and use our results to evaluate the carrier drift velocity along the edge [1]. The group velocity of these modes is a sum of the Hall conductivity contribution and the carrier drift velocity at the edge. In graphene, due to its particular dynamics and an abrupt edge, the drift velocity is expected to be of the order of the Fermi velocity, thus becoming experimentally accessible. We show EMP to exist by timing the travel of narrow wave-packets on picosecond time scales around exfoliated samples. They show chiral propagation with low attenuation at a velocity which is quantized on Hall plateaus. We extract the carrier drift contribution and find it to be slightly less than the Fermi velocity, as expected for an abrupt edge. We also extract the spatial spread of edge accumulated charge and find it to be narrower than for soft edge systems.

10:24AM A8.00013 Quantum spin Hall effect in the graphene zero energy Landau level - Part I , ANDREA F. YOUNG, JAVIER D. SANCHEZ-YAMAGISHI, BEN HUNT, PABLO JARILLO-HERRERO, RAY C. ASHOORI, MIT, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS — Shortly after the experimental discovery of graphene, it was predicted that Zeeman splitting of the graphene zero energy Landau level results in a quantum spin Hall phase, characterized by counterpropagating spin-filtered edge states. However, experimental realization of this state has been obscured by the existence of competing Coulomb interaction-driven insulating phases. We address this problem by fabricating monolayer graphene devices in which the Coulomb interaction is heavily screened by a proximal graphite gate. Despite the reduction in the strength of intralayer interactions, the resulting high mobility samples show all the usual signatures of Coulomb-driven symmetry breaking in high magnetic fields, with a strong insulating state developing at charge neutrality at fields of $\sim$1 Tesla. Unlike in conventional samples, however, we observe a continuous transition from this insulating state to a conducting state of order e^2/h as a function of in-plane field. Simultaneous high-sensitivity capacitance measurements reveal that the sample bulk remains gapped throughout the transition. The observation of finite conduction in the presence of a bulk insulator strongly implies that transport occurs via the edge states characteristic of the quantum spin Hall state.

10:36AM A8.00014 Quantum spin Hall effect in the graphene zero energy Landau level - Part II , JAVIER D. SANCHEZ-YAMAGISHI, ANDREA F. YOUNG, BENJAMIN HUNT, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, RAY C. ASHOORI, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Zeeman splitting of graphene's zeroth Landau level has been predicted to lead to a quantum spin Hall effect, but a competing interaction-driven insulating state has hampered previous attempts to drive the graphene into this regime. By using a proximal graphite gate to screen Coulomb interactions in the graphene, we are able to reduce the strength of this competing insulating state and observe a continuous transition to a conductive state as a function of in-plane field. We study this transition simultaneously in capacitance and transport, and find that despite conduction increasing by many orders of magnitude with in-plane field the bulk remains gapped throughout the transition. These observations indicate the continuous closing of a transport gap along the edge of the sample, with resulting counter-propagating edge states that are characteristic of the quantum spin Hall effect. We discuss the behavior of this transition across multiple samples with various levels of Coulomb screening, and present nonlocal multiterminal transport measurements designed to probe the nature of backscattering within the edge states. We also comment on the implications of our work for the rest of the graphene phase diagram at high magnetic fields.

10:48AM A8.00015 Role of the charge inhomogeneity on the breakdown of the quantum Hall effect in narrow single layer graphene devices[1] , CENK YANIK, ISMET KAYA, Sabanci University, QUANTUM TRANSPORT AND NANOELECTRONICS LABORATORY TEAM — The breakdown of the quantum Hall effect, which is observed as an abrupt escalation in the longitudinal resistance with an associated loss in the quantization of Hall voltage is the major obstacle against improving the resistance standard which is currently based on this effect. Graphene is inherently a 2D material and has an unusual band structure that allows the quantization of the Hall resistance even at room temperature. These unique properties of graphene make it a good candidate as a high precision metrological characterization tool for the quantum Hall resistance. The uncertainty in the quantum Hall resistance in graphene has been rapidly improving recently and graphene samples have already been shown to reach the precision of the current best 2DEG samples. In this talk, experimental results on the breakdown of the quantum Hall effect in graphene on SiOx is presented. In narrow graphene samples of 1 micrometer width, the charge inhomogeneity is quite prominent and strongly affects the nondissipative transport in the quantum Hall regime. It is observed that in such samples the quantization of the Hall resistance can retain at high current densities in the excess of 1 A/m even in the presence of dissipative potential along the longitudinal probes.

Session A9 FEd: Invited Session: Teaching Physics and Other STEM Subjects in an Urban Environment 308 - Mel Sabella, Chicago State University

8:00AM A9.00001 Away from the ivory tower: Real challenges teaching high school physics in an urban environment , RICHARD STEINBERG, City College of New York — For more than 20 years, I have been a physicist and a science educator, primarily at the college level. My research is on understanding and improving the learning of science, from elementary school science through quantum physics. Since 1999 I have been Professor in the School of Education and the Department of Physics and Program Director of Science Education at City College of New York. In that time I have had the privilege of working with hundreds of K-12 students, with over a thousand science teachers in and around New York City, and with even more college science students who are graduates of the city school system. To improve my ability to work with all these groups, I spent my sabbatical as a full time high school physics teacher in a public high school in New York City. For me, it was where the rubber meets the road. In this presentation, I will share experiences as an instructor and researcher from the perspectives of college physics instructor, science teacher educator, and high school teacher. With few exceptions, teachers are taught physics one way, are taught to teach it another, are put in a system where neither approach works, and have their students assessed in a way that promotes instructional strategies at odds with how students learn. I will share both challenges I encountered and what I learned about what works in this environment.

8:36AM A9.00002 Universities Reaching Outwards: Science Education Partnerships with Urban School Systems , CODY SANDIFER, Towson University — The goals of this talk are to: (1) describe how universities, physics departments, and individual faculty can partner with urban school systems to benefit K-16 students, teacher education programs, and university instructors, (2) summarize research on effective university-school system education partnerships, and (3) offer advice and share lessons learned so that university partners can avoid common pitfalls and maximize the potential for collaborative success. Possible areas of university-school collaboration include resident teachers, curricular review, early teaching experiences, demo sharing sessions, ongoing professional development, on- and off-campus science outreach, RET programs, science education resource centers, and others. University-school educational partnerships offer numerous benefits but can be challenging to implement and maintain. Research shows that most successful partnerships possess the following characteristics: mutual self-interest, participant commitment, mutual trust and respect, shared decision-making, information sharing, and ongoing evaluation. K-16 course and curriculum redesign is a specific issue that has its own unique set of contextual factors that impact the project's chance at success, including available materials, administrative support, formative assessments, pilot-testing and instructor feedback, and ongoing professional development. I have learned a number of lessons in own science education collaborations with the Baltimore City Public School System, which is an urban school system with 200 schools, 84,000 students, and 10,700 teachers and administrators. These lessons pertain to: communication, administrative power, and the structure of the school system; relevant contextual factors in the university and K-12 schools; and good old-fashioned common sense.[1] Specific advice on K-16 science education partnerships will be provided to help universities increase student and instructor satisfaction with their physics and teacher education programs, maintain a positive and mutually beneficial relationship with local schools, and improve science education at all levels of instruction.

[1]Common sense is encouraged, but not required, to attend the invited talk.

9:12AM A9.00003 Meeting Urban Science Students Where They Are: Perspectives from Two Physics Teachers and Four Schools[1] , ROSALIND ECHOLS[2], The Science Leadership Academy, Philadelphia PA — The phrase 'urban education' tends to be used in ways that suggest we see urban education (and urban students) as a monolithic construct. Often, 'urban' indexes children of color, with low levels of academic readiness from low socio-economic status communities in crowded, under-resourced classrooms taught by poorly prepared and/or poorly motivated teachers. While teachers and students in urban schools do face challenges that those in more suburban or rural areas may not, we argue that the differences across urban school contexts, even within the same city, outweigh the similarities. Furthermore, these differences have profound implications for the kind of work urban science teachers must do and the support they need from the science and science education research communities. In this talk, two high school physics teachers with experience in four radically different urban teaching contexts discuss the differences across schools that shape their teaching practice and their students' learning. Against this backdrop, we'll address the most common 'misconceptions' about inquiry science teaching in urban schools that we've encountered among scientists, science education researchers and teacher educators. The presentation will conclude with our synthesis of how scientists and science education researchers can best support urban science teachers and students.

9:48AM A9.00004 Engineering Education in K-12 Schools , ANNE SPENCE, UMBC Mechanical Engineering — Engineers rely on physicists as well as other scientists and mathematicians to explain the world in which we live. Engineers take this knowledge of the world and use it to create the world that never was. The teaching of physics and other sciences as well as mathematics is critical to maintaining our national workforce. Science and mathematics education are inherently different, however, from engineering education. Engineering educators seek to enable students to develop the habits of mind critical for innovation. Through understanding of the engineering design process and how it differs from the scientific method, students can apply problem and project based learning to solve the challenges facing society today. In this talk, I will discuss the elements critical to a solid K-12 engineering education that integrates science and mathematics to solve challenges throughout the world.

10:24AM A9.00005 Preparing teachers for ambitious *and*culturally responsive science teaching , GALE SEILER, McGill University — Communities, schools and classrooms across North America are becoming more ethnically, racially, and linguistically diverse, particularly in urban areas. Against this backdrop, underrepresentation of certain groups in science continues. Much attention has been devoted to multicultural education and the preparation of teachers for student diversity. In science education, much research has focused on classrooms as cultural spaces and the need for teachers to value and build upon students' everyday science knowledge and ways of sense-making. However it remains unclear how best to prepare science teachers for this kind of culturally responsive teaching. In attempting to envision how to prepare science teachers with cross-cultural competency, we can draw from a parallel line of research on preparing teachers for *ambitious science instruction*. In ambitious science instruction, students solve authentic problems and generate evidence and models to develop explanations of scientific phenomenon, an approach that necessitates great attention to students' thinking and sense-making, thus making it applicable to cultural relevance aims. In addition, this line of research on teacher preparation has developed specific tools and engages teachers in cycles of reflection and rehearsal as they develop instructional skills. While not addressing cross-cultural teaching specifically, this research provides insights into specific ways through which to prepare teachers for culturally responsive practices. In my presentation, I will report on efforts to join these two areas of research, that is, to combine ideas about multicultural science teacher preparation with what has been learned about how to develop ambitious science instruction. This research suggests a new model for urban science teacher preparation—one that focuses on developing specific teaching practices that elicit and build on student thinking, and doing so through cycles of individual and collective planning, rehearsal, review, and reflection. In this way, a defined set of science-specific, ambitious *and* culturally responsive instructional practices can be articulated and taught during science teacher preparation.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A10 DCOMP: Invited Session: Hard and Soft Materials Modeling, Simulations and Big Data 309 - Priya Vashishta, University of Southern California

8:00AM A10.00001 First-principles modeling of hard and soft matter[1] , ROBERTO CAR, Chemistry Department, Princeton University, Princeton NJ08544 — Electronic and atomistic processes are key to bio-inspired functional materials and nanocatalysts for energy applications. This talk will review recent simulation studies and discuss the challenges that first-principles quantum mechanical approaches face when addressing these issues.

[1]Supported by DOE-DE-FG02-06ER-46344, DOE-DE-SC0008626, DOE-DE-SC0005180, and NSF-CHE-0956500.

8:36AM A10.00002 First Principles based methods and applications for realistic simulations on complex soft materials to develop new materials for energy, health, and environmental sustainability , WILLIAM GODDARD, California Institute of Technology — For soft materials applications it is essential to obtain accurate descriptions of the weak (London dispersion, electrostatic) interactions between nonbond units, to include interactions with and stabilization by solvent, and to obtain accurate free energies and entropic changes during chemical, physical, and thermal processing. We will describe some of the advances being made in first principles based methods for treating soft materials with applications selected from new organic electrodes and electrolytes for batteries and fuel cells, forward osmosis for water cleanup, extended matter stable at ambient conditions, and drugs for modulating activation of GCPR membrane proteins,

9:12AM A10.00003 Nanoparticles in Complex Fluids, at Interfaces, in Polymers: Topology Matters , GARY S. GREST, Sandia National Laboratories, Albuquerque, NM — One versatile way to control the assembly and integration of nanoparticles is to tether organic molecules with specific functionalized groups to their surface. The tethers modify both inter particle interactions and their interaction with their surroundings, without disrupting the nanoparticles' unique properties. While it is often assumed that uniformly coating spherical nanoparticles with short organic ligands will lead to symmetric hybrids, using explicit-atom molecular dynamics simulations of model nanoparticles, we discovered that the hybrids exhibit a large variety of non-symmetric coatings, driving new pathways to control assemblies. These configurations of the coating stem from the high curvatures of small particles and comparable size tethers. In solution geometric factors dictate the symmetry of the hybrid and its stability, where the chain end-group coding and the solvent play only a secondary role. At water-vapor interface the anisotropic nanoparticle coatings seen in bulk solvents are enhanced. The coatings become significantly asymmetric and assume distinctive orientation with respect to the liquid interface. The asymmetry and degree of orientation depend strongly on the free volume provided by the geometry and the end group, as well as the solvent properties. At an interface asymmetric hybrids align with the surface to minimize free energy. These asymmetric coatings and oriented hybrids are expected to drive new self-assemblies symmetries in the bulk and at surfaces. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:48AM A10.00004 Translocation of Small Interfering RNA and Cholesterol Molecules in Biomembranes[1] , RAJIV KALIA, Collaboratory for Advanced Computing and Simulations, University of Southern California — This presentation will focus on all-atom molecular dynamics (MD) simulation studies of (1) structural and mechanical barriers to translocation of small interfering RNA (siRNA) across a phospholipid bilayer, and (2) flip-flop dynamics of cholesterol (CHOL) molecules across a phospholipid bilayer. In the first case, we find that the siRNA induces a liquid-to-gel phase transformation. In the gel phase we find large compressive lateral stresses in the hydrocarbon chains of lipid molecules, which present a considerable barrier to siRNA passage across the bilayer. In the second case, we study spontaneous CHOL inter-leaflet transport (flip-flop), the effect of this process on mechanical stresses across the bilayer, and the role of CHOL in inducing molecular order in bilayer leaflets. The simulation was run for 15 microseconds and we found 24 CHOL flip-flop events over that duration. On average, a CHOL molecule migrates across the lipid bilayer in about 73 ns after a flip-flop event is triggered. We have calculated diffusion maps and determined free energy surfaces and flip-flop mechanisms for CHOL molecules.

10:24AM A10.00005 Multiscale modeling of nanostructures for electronic and energy-related applications , EFTHIMIOS KAXIRAS, Department of Physics, Harvard University — The optimization of materials properties for opto-electronic and energy-related applications is a crucial component in the design of new devices. To this end, multiscale modeling of nanostructures is essential in understanding and predicting materials properties ranging from optical response to the mechanical failure. We present a number of examples where multiscale modeling has yielded useful information concerning the optimal choices for nanostructured device elements. These include the excitation and charge transfer processes in hybrid photovoltaic devices, the tuning of optical and electrical properties of layered materials like graphene and transition-metal-dichalcogenides, and the mechanical response and deformation of silicon-based high-energy-density electrodes.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A11 DPOLY: Invited Session: Directed Assembly of Hybrid Materials 310 - Richard Vaia, Air Force Research Laboratory

8:00AM A11.00001 Engineered Self-Assembly of Plasmonic Nanomaterials , ANDREA TAO, University of California, San Diego — A critical need in nanotechnology is the development of new tools and methods to organize, connect, and integrate solid-state nanocomponents. Self-assembly – where components spontaneously organize themselves – can be carried out on a massively parallel scale to construct large-scale architectures using solid-state nanocrystal building blocks. I will present our recent work on the synthesis and self-assembly of nanocrystals for plasmonics, where light is propagated, manipulated, and confined by solid-state components that are smaller than the wavelength of light itself. We show the organization of polymer-grafted metal nanocrystals into hierarchical nanojunction arrays that possess intense "hot spots" due to electromagnetic field localization. We also show that doped semiconductor nanocrystals can serve as a new class of plasmonic building blocks, where shape and carrier density can be actively tuned to engineer plasmon resonances. These examples demonstrate that nanocrystals possess unique electromagnetic properties that rival top-down structures, and the potential of self-assembly for fabricating designer plasmonic materials.

8:36AM A11.00002 Polymer Functionalized Nanoparticles in Polymer Nanocomposites , ARTHI JAYARAMAN, University of Colorado at Boulder — Significant interest has grown around the ability to control spatial arrangement of nanoparticles in a polymer nanocomposite to engineer materials with target properties. Past work has shown that one could achieve controlled assembly of nanoparticles in the polymer matrix by functionalizing nanoparticle surfaces with homopolymers. This talk will focus on our recent work using Polymer Reference Interaction Site Model (PRISM) theory and Monte Carlo simulations and GPU-based molecular dynamics simulations to specifically understand how heterogeneity in the polymer functionalization in the form of a) copolymers with varying monomer chemistry and monomer sequence, and b) polydispersity in homopolymer grafts can tune effective interactions between functionalized nanoparticles, and the assembly of functionalized nanoparticles.

9:12AM A11.00003 Gels from soft hairy nanoparticles in polymeric matrices , DIMITRIS VLASSOPOULOS, FORTH and University of Crete, Department of Materials Science and Technology, Heraklion — Hairy particles represent a huge class of soft colloids with tunable interactions and properties. Advances in synthetic chemistry have enabled obtaining well-characterized such systems for specific needs. In this talk we present two model hairy soft particles with diameters of the order of tens of nanometers, star polymers and polymerically grafted spherical particles. In particular, we discuss design strategies for dispersing them in polymeric matrices and eventually creating and breaking gels. Control parameters are the matrix molar mass, the grafting density (or functionality) and the size of the grafts (or arms). The linear viscoelastic properties and slow time evolution of the gels are examined in view of the existing knowledge from colloidal gels consisting of micron-sized particles, and compared. In the case of stars we start from a concentrated glassy suspension in molecular solvent and add homopolymer at increasing concentration, and as a result of the induced osmotic pressure the stars shrink and a depletion gel is formed. For the grafted colloidal particles, they are added at low concentration to a polymer matrix, and it has been shown that under certain conditions the anisotropy of interactions gives rise to network formation. We then focus on the nonlinear rheological response and in particular the effect of shear flow in inducing a solid to liquid transition. Our studies show that the yielding process is gradual and shares many common features with that of flocculated colloidal suspensions, irrespectively of the shape of the building block of the gel. Whereas shear can melt such a gel, it cannot break it into its constituent blocks and hence fully disperse the hairy nanoparticles. On the other hand, the hairy particles are intrinsically hybrid. We show how this important feature is reflected on the heating of the gels. In that case, the mismatch of thermal expansion coefficients of core and shell appears to play a role on the particle response as it imposes and internal strain on the particle, which in turn changes the shell conformation and under some conditions can lead to thermal melting of the gel. These alternative avenues for manipulating the gel-to-liquid transition have potential implications in directing the properties of hairy nanoparticles and their assemblies in viscoelastic matrices. Parts of this work reflect collaboration with D. Truzzolillo (FORTH), J. F. Moll and S. K.Kumar (Columbia). R. H. Colby (Penn State), M. Gauthier (Waterloo) and B. C. Benicewicz (Univ. South Carolina).

9:48AM A11.00004 Canopy Dynamics in Nanoscale Ionic Materials Probed by NMR , PETER MIRAU, Air Force Research Labortories — Nanoscale ionic materials (NIMs) are hybrids prepared from ionically functionalized nanoparticles (NP) neutralized by oligomeric polymer counter-ions. NIMs are designed to behave as liquids under ambient conditions in the absence of solvent and have no volatile organic content, making them useful for a number of applications. We have used NMR relaxation and pulse-field gradient NMR to probe local and collective canopy dynamics in NIMs based on silica nanoparticles (NP), fullerols and proteins in order to understand the relationship between the core and canopy structure and the bulk properties. The NMR studies show that the canopy dynamics depend on the degree of neutralization, the canopy radius of gyration and molecular crowding at the ionically modified NP surface. The viscosity in NIMs can be directly controlled with the addition of ions that enhance the exchange rate for polymers at the NP surface. These results show that NIMs for many applications can be prepared by controlling the dynamics of the NP interface.

10:24AM A11.00005 Colloidal Crystallization in Confinement: Icosahedral Symmetry & Plastic-Crystal Transitions , ALFONS VAN BLAADEREN, Utrecht University, Debye Institute — The crystallization of spherical nanoparticles in liquid droplets results under certain conditions in crystals with an icosahedral shape. Experiments with larger spherical colloids and computers simulations of hard particles demonstrate that such crystal shapes do not rely on energetic arguments, but already result from confinement and entropy alone. Experiments on rod shaped fluorescent colloidal particles that are monodisperse enough to form nematic and smectic liquid crystal phases under conditions where the double layer thickness is small compared to the diameter of the rods show that if the double layer thickness is significantly larger than the rod length plastic crystals with a body centered crystal structure are formed. In such crystals there is three dimensional positional order, but no orientational order of the rods. These plastic crystals under strong planar confinement show intriguing phase behavior where plastic crystal and full crystal phases alternate as a function of the separation between the confining plates.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A12 DMP: Focus Session: Complex Oxide Interfaces - Nickelates 314 - Prasana Balachandran, Drexel University

8:00AM A12.00001 Designing a Spin-one Mott Insulator: Complete Charge Transfer in Nickelate-Titanate Heterostructures[1] , HANGHUI CHEN, Department of Physics, Columbia University, CHRIS MARIANETTI, Department of Applied Physics and Applied Math, ANDREW MILLIS, Department of Physics, Columbia University — *Ab initio* calculations are performed to show that complete charge transfer may occur from the TiO_2 to the NiO_2 layers in $(LaTiO_3)_1/(LaNiO_3)_1$ superlattices. Although the two component materials are an $S = 1/2$ Mott insulator and a weakly correlated paramagnetic metal, strong correlation effects on Ni d states can render the superlattice an unusual $S = 1$ charge transfer insulator, with the Ti-d band empty, the Ni in the d^8 state and the oxygen bands filled. The charge transfer gap is set by the Ti/Ni d level splitting. Magnetic, photoemission and x-ray scattering experiments are suggested to test the theory. The results show that heterostructuring can lead to very high levels of electron doping of oxides.

[1]This research was supported by the Army Research Office under ARO-Ph 56032 and DOE-ER-046169.

8:12AM A12.00002 Two dimensional Mott physics in the rare earth nickelates , ANKIT DISA, DIVINE KUMAH, JOSEPH NGAI, JARRETT MOYER, FRED WALKER, CHARLES AHN, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University — The strong electron correlations inherent in the rare-earth nickelate system ($RNiO_3$) lead to a metal-insulator transition, the temperature of which can be tuned by changing the rare-earth ion, R. Bulk $LaNiO_3$ is metallic at all temperatures, and $NdNiO_3$ undergoes a metal-insulator transition at 150 K. However, reducing the thickness of both $LaNiO_3$ and $NdNiO_3$ strongly affects the transport behavior, where $LaNiO_3$ undergoes a thickness-driven metal-insulator transition below $\sim$4 unit cells. Here, we identify the physics of this transition and demonstrate two-dimensional metallic behavior in thin films. We show that by direct chemical doping of $LaNiO_3$ thin films we can restore metallic behavior and tune the conductivity. We apply the same technique to thin films of $NdNiO_3$ and control the metal-insulator transition temperature. Finally, combining artificial confinement and doping, we observe metallicity in nickelate layers as thin as two unit cells. The effects of both structural and charge-carrier modifications on the transport properties of the thin films will be discussed.

8:24AM A12.00003 Epitaxial growth of (111)-oriented $LaAlO_3/LaNiO_3$ ultra-thin superlattices , S. MIDDEY, D. MEYERS, M. KAREEV, E.J. MOON, B.A. GRAY, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA — The epitaxial stabilization of a single layer or superlattice structures composed of complex oxide materials on polar (111) surfaces is severely burdened by reconstructions at the interface, that commonly arise to neutralize the polarity. We report on the synthesis of high quality $LaNiO_3/mLaAlO_3$ pseudo cubic (111) superlattices on polar (111)-oriented $LaAlO_3$, the proposed complex oxide candidate for a topological insulating behavior. Comprehensive X-Ray diffraction measurements, RHEED, and element specific resonant X-ray absorption spectroscopy affirm their high structural and chemical quality. The study offers an opportunity to fabricate interesting interface and topology controlled (111) oriented superlattices based on ortho-nickelates.

8:36AM A12.00004 Topological phases in complex oxide interfaces and heterostructures[1] , GREGORY A. FIETE[2], University of Texas at Austin — In this talk we highlight recent theoretical work from our group aimed at identifying complex oxide interfaces and heterostructures that are expected to support topological phases, namely the Z_2 time-reversal invariant topological insulator and the zero magnetic field Chern insulator, or quantum anomalous Hall state. We focus on two particular systems: (1) Perovskites of the form ABO_3 and (2) Pyrochlores of the form $A_2B_2O_7$ where A is usually a rare earth element and B is a transition metal element. One of our main results is that thin film growth along the [111] direction is favorable for the realization of topological phases in experiment. We lay out the most important film properties that appear to favor topological phases and discuss the different physics associated with realizing topological phases in 3d, 4d, and the heaviest 5d-based transition metal oxide systems. Key open questions and experimental challenges are presented, as well as the potential advantages that oxide systems offer over the Bi-based topological insulator material class in device applications.

9:12AM A12.00005 Controlling the metal insulator transition using the ferroelectric field effect in rare earth nickelates[1] , MATTHEW MARSHALL, ANKIT DISA, DIVINE KUMAH, HANGHUI CHEN, SOHRAB ISMAIL-BEIGI, FRED WALKER, CHARLES AHN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena (CRISP), Yale University — A ferroelectric field effect transistor (FE-FET) modulates conductivity in a non-volatile manner by electrostatically accumulating and depleting charge carriers at the interface between a conducting channel and ferroelectric gate. The rare earth nickelate $LaNiO_3$ is metallic in bulk, while other rare earth nickelates, such as $NdNiO_3$, exhibit metal-insulator transitions and anti-ferromagnetic behavior in the bulk. Here, we show that by coupling the ferroelectric polarization of $Pb_{0.8}Zr_{0.2}TiO_3$ (PZT) to the carriers in a nickelate, we can dynamically induce a metal- insulator transition in ultra-thin films of LaNiO3, and induce large changes in the MIT transition temperature in NdNiO3. Density functional theory is used to determine changes in the physical and electronic Ni-O-Ni bond angle of the nickelate at the interface between PZT and LaNiO3. The effect of the ferroelectric polarization is to decrease the Ni-O-Ni bond angle from 180 degrees and increase the carrier effective mass. Related to this change in electronic structure, we observe a change in resistivity of approximately 80% at room temperature for an ultra-thin 3 unit cell thick film of $LaNiO_3$.

[1]Work supported by FENA and the NSF under MRSEC DMR 1119826.

9:24AM A12.00006 Atomic-scale structure and composition mapping in nickelate heterostructures , DIVINE KUMAH, ANKIT DISA, JOSEPH NGAI, HANGHUI CHEN, SOHRAB ISMAIL-BEIGI, CHARLES AHN, FRED WALKER, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University, New Haven, CT — Strongly correlated electronic systems display a wide range of interesting properties, including ferroelectricity, superconductivity, metal-insulator transitions, and novel magnetic phenomena. The electrical and magnetic properties of thin film heterostructures based on these systems are directly linked to their atomic scale structure and composition. This link is important for the rare earth nickelates, which exhibit first-order metal-insulator transitions, antiferromagnetism, and charge ordering. At the interfaces present in these systems, structural coupling can lead to new effects. We use a synchrotron-based resonant anomalous x-ray scattering method to elucidate the physical and electronic structure at complex oxide heterointerfaces of nickelates grown using molecular beam epitaxy. Temperature dependent resonant x-ray studies in doped 8 unit-cell thick $NdNiO_3$ films reveal subtle changes in atomic structure and Ni charge disproportionation at the metal-insulator transition.

9:36AM A12.00007 Ultrafast phase control in complex oxide heterostructures , ANDREA CAVIGLIA, Kavli Institute of Nanoscience, Delft University of Technology, the Netherlands — Complex oxide heterostructures have emerged as multifunctional materials of striking flexibility, in which unconventional electronic phases can be realised by engineering the strain field across interfaces. This same mechanical coupling is also expected to be effective on the ultrafast timescale, and could be exploited for the dynamic control of materials properties. Here, we demonstrate that a large-amplitude mid-infrared field, made resonant with a stretching mode of the substrate, can switch the electronic properties of a thin film across an interface. Exploiting dynamic vibrational propagation between different components of a heterostructure, insulating antiferromagnetic $NdNiO_3$ is driven through a prompt, five-order-of-magnitude increase of the electrical conductivity, with resonant frequency and susceptibility that is controlled by choice of the substrate material. Vibrational phase control, extended here to a wide class of heterostructures and interfaces, may be conducive to new strategies for electronic phase control at THz repetition rates.

10:12AM A12.00008 Investigation of Nonlinear Differential Conductance in $NdNiO_3$ Thin Films , WILL HARDY, HENG JI, Department of Physics and Astronomy, Rice University, JUNWOO SON, Department of Materials Science and Engineering, Pohang University of Science and Technology, Republic of Korea, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — We will report on recent investigations of the voltage and temperature dependence of the nonlinear differential conductance, dI/dV, of the insulating state in thin films of $NdNiO_3$. This compound exhibits a metal-insulator transition near 100 K [1] between a high temperature paramagnetic metal and a low temperature charge-transfer insulator. These investigations are motivated by previous observations in Fe_3O_4, a strongly correlated material that undergoes the Verwey transition at a similar temperature scale, in which hysteretic, voltage-driven breakdown of the insulating state has been reported [2]. We examine the evolution of the nonlinear conductance, as well as its dependence on the device geometry, in planar devices at temperatures near the transition.

10:24AM A12.00009 Strain mediated suppression of the metal-insulator and anti-ferromagnetic transition in EuNiO3 thin films , DEREK MEYERS, SRIMANTA MIDDEY, MIKHAIL KAREEV, BENJAMIN GRAY, Department of Physics, University of Arkansas, Fayetteville, AR 72701, JOHN FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, USA, JAK CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, AR 72701 — Ultrathin epitaxial films of $EuNiO_3$ were grown on a series of substrates traversing highly compressive (-2.4%) to highly tensile (2.5%) lattice mismatch. X-ray absorption spectroscopy measurements revealed a strong multiplet splitting in the tensile samples that progressively weakens with increasing compressive strain. Transport measurements further collaborated these findings, showing a successively (from tensile to compressive) lower resistance and a complete suppression of the metal-insulator transition at -2.4% lattice mismatch. The derivative of the transport showed a strong downturn around the bulk Neel temperature, which was also suppressed with compressive strain.

10:36AM A12.00010 Composition spread studies of $Nd_{1-x}La_xNiO_3$ combinatorial thin films[1] , RICHARD SUCHOSKI, MSE Department and CNAM, UMD College Park, KUI JIN, Physics Department and CNAM, UMD College Park, SHINTARO YASUI, MSE Department and CNAM, UMD College Park, RICHARD GREENE, Physics Department and CNAM, UMD College Park, ICHIRO TAKEUCHI, MSE Department and CNAM, UMD College Park — Rare earth nickelates have attracted a great deal of attention in recent years due to a host of interesting features, one being a transition from paramagnetic metal to antiferromagnetic insulator through distortions from the ideal perovskite unit cell. This metal-to-insulator transition (MIT) can be manipulated by modifying variables such as temperature, rare earth ion size, oxygen content, or stress from lattice-mismatched epitaxial thin film growth. Research on this family has been extensive, though there still exists an absence of thin film studies focusing on intermediate compositions. We have fabricated epitaxial thin film composition spreads of $Nd_{1-x}La_xNiO_3$ grown via combinatorial PLD to investigate these transitional compositions. While our films exhibit a smooth composition progression, we observe a composition threshold where orthorhombic $NdNiO_3$ transforms to rhombohedral $LaNiO_3$, correlating with disappearance of the MIT, and displays a non-Vegard evolution of the film's in-plane lattice constant in HRXRD and Raman scattering data of the A_{1g} rotational mode.

10:48AM A12.00011 First-principles study of the properties of oxygen-deficient $LaNiO_{3-x}$ structures , ANDREI MALASHEVICH, SOHRAB ISMAIL-BEIGI, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University — There has been a great deal of recent interest and activity regarding rare earth nickelates in bulk form, as superlattices, and as thin films. The parent nickelate in these cases is typically $LaNiO_3$, which in bulk form is a paramagnetic metal. In addition, due to its relatively good lattice match to other perovskites, it also serves as an electrode in functional oxide film devices. However, it is known that the conductivity of $LaNiO_3$ in any form is strongly affected by the presence of oxygen vacancies. Here, we present a first-principles study of a variety of oxygen-deficient $LaNiO_{3-x}$ structures. We describe our theoretical results for the atomic-scale geometry and energetics of the vacancies (formation and aggregation), their mobilities, and their electronic structure.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A13 DMP: Focus Session: Topological Materials - Magnetic Topological Insulators 315

- Michael Fhurer, Monash University

8:00AM A13.00001 Ab initio study of topological surface states of Sb (111) surface with magnetic impurities , JINHEE HAN, HYUNGJUN LEE, HYOUNG JOON CHOI , Department of Physics and IPAP, Yonsei University — We study effects of magnetic impurities on topological surface state of Sb (111) surface by using an ab-initio pseudopotential density-functional method. We have implemented the spin-orbit interaction into the SIESTA code in a form of additional fully non-local projectors. To calculate surface band structures, we use a slab of Sb using a 4x4 supercell containing 20 atomic layers. In particular, we compare Fe impurities with Mn impurities, whose atoms have larger magnetic moments, and compare interstitial impurities with substitutional impurities for each atom. To understand the impurity effects on the topological surface states, we simulate ARPES spectra and calculate projected density of states of impurity near Fermi level. This work was supported by NRF of KOREA (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2012-C2-14).

8:12AM A13.00002 Manipulating Surface-induced Ferromagnetism in Modulation-doped Topological Insulators[1] , XUFENG KOU, LIANG HE, MURONG LANG, YABIN FAN, University of California, Los Angeles, YING JIANG, YONG WANG, Zhejiang University, FAXIAN XIU, Iowa State University, KANG WANG, University of California, Los Angeles, DEVICE RESEARCH LABORATORY TEAM, CENTER FOR ELECTRON MICROSCOPY AND STATE KEY LABORATORY OF SILICON MATERIALS COLLABORATION, ECE DEPARTMENT COLLABORATION — The manipulation of topological surface states is a key to realize applicable devices of topological insulators. In addition to the direct engineering of time-reversal-symmetry protected surface states, recent work suggests that various physical responses can be obtained from surface helical states by integrating additional ferromagnetism or superconductivity to the original topological order. Here, we report the coexistence and tunability of bulk carrier density-independent and surface-mediated electrically controllable ferromagnetisms in modulation-doped Crx(BiySb1-y)2Te3 epitaxial thin films. We demonstrate for the first time a dramatic enhancement of surface-induced magnetization on TI / Cr-TI bilayer devices. The surface magneto-electric effects can be either enhanced significantly or completely switched-off, by tuning the separation of the surface from the magnetic impurities. The electric-field-modulated ferromagnetism in our modulation-doped TI hetero-structures is fundamentally important for the realization of the quantum anomalous Hall Effect as well as the axion electromagnetic dynamics, and thus provides a new approach for spintronics applications.

[1]The authors would also like to acknowledge helpful discussions with Dr. Alexei Fedorov and Dr. Mathew Marcus from the Advanced Light Source at Berkeley.

8:24AM A13.00003 Effect of Magnetic Doping on Electrical and Thermal Conductivities and Seebeck Coefficient of Suspended Bismuth Telluride Nanoplates , INSUN JO, Department of Physics, The University of Texas at Austin, Austin, TX78712, USA, MICHAEL THOMPSON PETTES, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX78712, ZHEN YAO, Department of Physics, The University of Texas at Austin, Austin, TX78712, USA, LI SHI, Department of Mechanical Engineering, The University of Texas at Austin, Austin, TX78712 — Bismuth telluride has been investigated intensively as a model system for topological insulators. In this work, we have studied electrical and thermal transport properties of suspended bismuth telluride nanoplates grown by the vapor-solid method. The thin crystals were transferred onto micro-fabricated suspended structures with built-in electrodes and thermometers, which allowed us to measure electrical (σ) and thermal (κ) conductivities as well as the Seebeck coefficient (S). The through-etched hole in the devices enabled us to evaporate Cr layers on both surfaces of the crystal. After H_2 annealing at 500 K, we measured enhanced σ, κ, and S values by 40, 10, and 20%, respectively. In comparison, H_2 annealing without Cr evaporation resulted in 10, 10, and -8% changes of σ, κ, and S values, respectively. The effect of magnetic doping by Cr will be discussed. Additionally, magneto-transport measurements were performed on the samples to resolve the transport properties of the surface states. We observed a pronounced weak anti-localization feature in undoped samples. Changes in this feature after Cr doping will be presented.

8:36AM A13.00004 Electrical control of the ferromagnetism in $Sb_{2-x}Cr_xTe_3$ magnetic topological insulators , ZUOCHENG ZHANG, XIAO FENG, MINGHUA GUO, CUICU CHANG, JINSONG ZHANG, Tsinghua University, KANG LI, LILI WANG, Institute of Physics, Chinese Academy of Sciences, XI CHEN, Tsinghua University, KE HE, Institute of Physics, Chinese Academy of Sciences, QIKUN XUE, Tsinghua University, XUCUN MA, Institute of Physics, Chinese Academy of Sciences, YAYU WANG, Tsinghua University, TSINGHUA UNIVERSITY TEAM, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES COLLABORATION — The spin helical Dirac fermions living on the surface of three-dimensional topological insulators (TIs) provide a platform for exploring the coupling between the charge and spin degrees of freedom. In particular, breaking the time reversal symmetry in TIs is expected to create exotic topological magnetoelectric effects. To realize these phenomena and apply them in TI-based spintronic devices, it is desirable to achieve in situ manipulation of the magnetism in TIs via an electrical field. In this talk we present the fabrication and transport studies of Cr doped Sb_2Te_3 magnetic TI thin films. By applying a gate voltage in a field effect transistor device, we can control the coercive force and Curie temperature. The ferromagnetic order is found to be enhanced when more hole-type carriers are injected into the sample. This trend suggests the itinerant bulk holes in TIs can mediate ferromagnetic ordering of local moments in a similar manner as that in the diluted magnetic semiconductors. The electrical control of the ferromagnetism in TIs demonstrated here paves the road for realizing the TI-based devices.

8:48AM A13.00005 Ferromagnetism in Mn-doped Bi_2Te_3 Thin Films by Molecular Beam Epitaxy , JOON SUE LEE, ANTHONY RICHARDELLA, DAVID W. RENCH, DUMING ZHANG, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park, PA 16802 — We demonstrate the ferromagnetic properties of Mn-doped thin films of the topological insulator Bi_2Te_3 grown by molecular beam epitaxy. Films with Mn concentrations up to 10% and thickness up to 60 nm were studied. The electrical transport measurements reveal a strong anomalous Hall effect (AHE) with a coercive field of 3000 Oe at 500 mK. The onset (10 - 16 K) of the AHE is at about the same temperature with the Tc obtained by the superconducting quantum interference device (SQUID) measurements. The magneto-conductivity shows hysteresis and a crossover from weak antilocalization to weak localization when going below Tc. The carrier type and the carrier concentration are modified by varying the Mn doping and the film thickness. Most of films are n-type, but some films thicker than 50 nm at a certain Mn concentration are p-type. Shifts in x-ray diffraction indicate that the n-type films have Mn atoms between quintuple layers, but the p-type films are substitutional. Funded by ONR and DARPA.

9:00AM A13.00006 Metallic states in Topological Insulators with Magnetic Impurities[1] , LEONARDO ABDALLA, ADALBERTO FAZZIO, Instituto de Física, Universidade de São Paulo, TOME SCHMIDT, ROBERTO MIWA, Instituto de Física, Universidade Federal de Uberlândia — Topological insulators are characterized by an insulating bulk, and an odd number of Dirac cones in the surface. Their existence are due a band inversion in the bulk phase created by a strong spin orbit coupling. Those metallic states have their spin polarization locked in a plane giving rise to a chiral spin texture, similar to the quantum spin hall effect. Such spin helicity suppresses backscattering processes. Based on first principles calculations, we performed a systematic study of transition metal (TM) impurities (Co, Mn, Ni, Cr and Fe) lying on the topmost layers of the Bi_2Se_3 topological insulator. Based upon formation energy results, by considering a number of plausible configurations, we find an energetic preference for the TMs occupying the topmost Bi substitutional site, and the subsurface interstitial sites neighboring Bi atoms. Our simulated scanning tunneling images (STM) show that there is local perturbation on the electronic structure of the surface. Further electronic band structure calculations indicate that (for some systems) the topologically protected surface metallic bands are suppressed, opening a band gap. In those systems the time reversal symmetry has been broken due to the formation net magnetic moment aligned perpendicularly to the surface plane.

9:12AM A13.00007 Electrical transport studies in the topological insulator Bi_2Se_3 with exchange induced ferromagnetism[1] , PENG WEI, FERHAT KATMIS, Francis Bitter Magnet Lab, MIT, Cambridge, MA, BADIH ASSAF, DONALD HEIMAN, Department of Physics, Northeastern University, Boston, MA, JAGADEESH MOODERA, Francis Bitter Magnet Lab and Department of Physics, MIT, Cambridge, MA — The proximity-induced ferromagnetic order in topological insulator (TI)/ferromagnetic insulator (FI) heterostructures induces ferromagnetism in TI, which breaks local time reversal symmetry that can lead to many exotic properties, such as image magnetic monopole, topological magneto-electric effects, etc.[1] We achieved this novel ferromagnetic order in a TI Bi_2Se_3 through Bi_2Se_3/EuS bi-layer structures. Electric transport studies show a dramatic suppression of the weak anti-localization (WAL) effect in Bi_2Se_3/EuS compared to controlled Bi_2Se_3 samples. In contrast to the case of surface doping a TI with magnetic atoms (i.e. Fe), here the WAL cannot be quenched even with a full coverage EuS capping layer, which points that its origin can be the opening of a surface gap rather than a reduction of the magnetic scattering length. The results are analyzed with a theoretical model providing a value for the induced surface exchange gap. Other experimental results, such as the anomalous Hall effect that support the proximity induced ferromagnetism in Bi_2Se_3 will be discussed.

9:24AM A13.00008 Magnetotransport in topological insulator-ferromagnetic insulator heterostructure devices[1] , ABHINAV KANDALA, ANTHONY RICHARDELLA, DAVID RENCH, DUMING ZHANG, THOMAS FLANAGAN, NITIN SAMARTH, Penn State University — Topological surface states modified by the presence of magnetism are predicted to play host to a number of exotic phenomena and are of great fundamental as well as applied interest. Interfacing topological insulators with magnetic insulators offers a unique opportunity to access these effects by transport, without affecting the bulk band structure. We demonstrate the integration of MBE grown thin films of Bi_2Se_3 with the insulating ferromagnet GdN. SQUID measurements of the hetero-structure reveal an in-plane easy axis with a ferromagnetic Curie temperature $T_c \sim 13$ K. The fabrication of hall devices with bare and GdN-capped channels enables direct comparison of magneto-transport properties. While the bare channel displays conventional weak anti-localization (WAL), the capped channel reveals a weakened WAL and a superimposed negative magnetoresistance (MR) associated with weak localization. These observations are discussed in the context of gap-opening in the Dirac surface state. Finally, we discuss the observation of hysteresis in the MR of the capped channel below 2 K.

9:36AM A13.00009 Dirac Surface State of Metamagnetic Topological Insulators , Y.S. HOR, S.H. LEE, J.E. MEDVEDEVA, Missouri University of Science and Technology, M. IAVARONE, Temple University, U. CHATTERJEE, Argonne National Laboratory, W. RATCLIFF, NCNR — We report the observation of metamagnetism in iron-doped bismuth selenide topological insulators. The structural, magnetic, and transport properties of the materials were investigated both computationally and experimentally. First-principles density functional calculations are employed to determine the most favorable site location of the iron atoms in the bismuth selenide lattice and to analyze the magnetic properties of the resulting structures. Magnetization measurements showed the system is anisotropic with a magnetic phase transition at $\sim$ 100 K. However, this magnetic-doped topological insulator did not show an opening of a surface gap in ARPES data at temperatures below the transition temperature. This is due to the antiferromagnetic ground state of the system. With an applied magnetic field greater than 300 Oe, the system becomes ferromagnetic. In addition, Shubnikov-de Haas oscillations were observed in the longitudinal resistivity measurements under the applied magnetic fields up to 9 T.

9:48AM A13.00010 Experimental Realizations of Magnetic Topological Insulator and Topological Crystalline Insulator[1] , SUYANG XU, Princeton Univeristy — Over the past few years the experimental research on three-dimensional topological insulators have emerged as one of the most rapidly developing fields in condensed matter physics. In this talk, we report on two new developments in the field: The first part is on the dynamic interplay between ferromagnetism and the Z_2 topological insulator state (leading to a magnetic topological insulator). We present our spin-resolved photoemission and magnetic dichroic experiments on MBE grown films where a hedgehog-like spin texture is revealed on the magnetically ordered surface of Mn-Bi_2Se_3 revealing a Berry's phase gradient in energy-momentum space of the crystal. A chemically/electrically tunable Berry's phase switch is further demonstrated via the tuning of the spin groundstate in Mn-Bi_2Se_3 revealed in our data (Nature Physics 8, 616 (2012)). The second part of this talk describes our experimental observation of a new topological phase of matter, namely a topological crystalline insulator where space group symmetries replace the role of time-reversal symmetry in an otherwise Z_2 topological insulator predicted in theory. We experimentally investigate the possibility of a mirror symmetry protected topological phase transition in the $Pb_{1-x}Sn_xTe$ alloy system, which has long been known to contain an even number of band inversions based on band theory. Our experimental results show that at a composition below the theoretically predicted band inversion, the system is fully gapped, whereas in the band-inverted regime, the surface exhibits even number of spin-polarized Dirac cone states revealing mirror-protected topological order (Nature Communications 3, 1192 (2012)) distinct from that observed in Z_2 topological insulators. We discuss future experimental possibilities opened up by these new developments in topological insulators research. This work is in collaboration with M. Neupane, C. Liu, N. Alidoust, I. Belopolski, D. Qian, D.M. Zhang, A. Richardella, A. Marcinkova, Q. Gibson, R. Sankar, Y.J. Wang, T. Chang, H. Jeng, H. Lin, L.A. Wray, J.D. Denlinger, M. Leandersson, T. Balasubramanian, J. Sánchez-Barriga, O. Rader, G. Landolt, B. Slomski, J.H. Dil, F.C. Chou, E. Morosan, N. Samarth, R.J. Cava and M.Z. Hasan.

10:24AM A13.00011 Efficient Generation of Spin Current and Spin Transfer Torque by the Topological Insulator Bismuth Selenide , ALEX MELLNIK, JENNIFER GRAB, PETER MINTUN, Department of Physics, Cornell University, JOON SUE LEE, ANTHONY RICHARDELLA, NITIN SAMARTH, Deptartment of Physics, Penn State University, DANIEL RALPH, Department of Physics, Cornell University — We study the use of topological insulators as a source of spin current for applying spin transfer torque to a ferromagnet. We fabricate bismuth selenide / permalloy bilayers and use the spin-torque FMR technique to make quantitative measurements of the torque applied to the magnetic permalloy layer resulting from an in-plane current. Despite the fact that only a small fraction of the current flows in the bismuth selenide, we still observe large spin torque effects. There is a component of torque in the sample plane with the symmetry expected from the spin Hall effect, with a strength corresponding to a spin Hall angle greater than 1, larger than measured for any other material. There is also an additional out-of-plane, field-like torque several times larger than expected from the Oersted field. We will discuss the dependence of these effects on layer thickness, and attempt to distinguish whether they result from bulk or surface-state effects.

10:36AM A13.00012 Surface state driven spin-torque in topological-insulator / ferromagnetic-metal bilayers , MARK H. FISCHER, ABOLHASSAN VAEZI, Cornell University, AURELIEN MANCHON, King Abdullah University of Science and Technology (KAUST), EUN-AH KIM, Cornell University — A hallmark of surface states in strong 3D topological insulators (TI) is the helical spin texture. While there have been proposals on exploiting this spin texture for spintronics applications, they focused on TI/ferromagnetic-insulator (FI) structures predicting field-like torque due to spin accumulation. Motivated by recent spin-torque experiments on Pt/ferromagnetic-metal(FM) structures, we consider a TI/FM bilayer, where the magnetic moment as well as the current driven through the system are in plane. While existing TIs have a conducting bulk, recent transport experiments showed that the main contribution to the current in Bi_2Se_3 thin films comes from two distinct surface states: the topological Dirac surface state and an additional 2D electron gas with Rashba spin-orbit coupling. We thus consider spin torque in the TI/FM structure due to these two surface states. We find that each surface state leads to out-of-plane (field-like) torque due to current driven spin accumulation. Moreover, we find an in-plane torque due to spin diffusion into the FM, an effect absent in TI/FI structures. Interestingly, the two surface states contribute with opposite sign to the spin density. This allows for the experimental identification of the dominant state based on its sign.

10:48AM A13.00013 Topological Magnetic Heterostructures of Epitaxial Bi_2Se_3 on $Ga_{1-x}Mn_xAs$, ANTHONY RICHARDELLA, JOON SUE LEE, DAVID W. RENCH, ROBBIE D. FRALEIGH, NITIN SAMARTH, Dept. of Physics and Center for Nanoscale Science, Penn State University, University Park PA 16802 — Topological Insulators (TI) are characterized by conducting surface states with a Dirac-like dispersion protected by time reversal symmetry. A magnetic perturbation that breaks this symmetry, such as placing a ferromagnet in proximity with a TI, can lead to a wide range of unusual effects such as a half integer quantum Hall conductance, magnetic monopoles, or an inverse spin-galvanic effect, among others. Such structures are challenging to create however due to the difficulty in finding insulating magnetic materials that are compatible with topological materials. We demonstrate one approach to this, the epitaxial growth of Bi_2Se_3 on the ferromagnetic semiconductor $Ga_{1-x}Mn_xAs$. We discuss the growth and characterization of these heterostructures, where the Mn concentration of the GaMnAs can be tuned from a highly resistive state near the metal-insulator transition, up to a highly doped semiconductor with a T_C well in excess of 100 K. This allows the study of a wide range of regimes and interactions between the two layers. As GaMnAs is a prototypical material for the demonstration of many spintronic devices, and has a highly tunable anisotropy, this opens up the possibility of an exciting range of hybrid spintronic/Topological Insulator structures. Funded by ONR and DARPA.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A14 DMP GMAG: Focus Session: Perovskite Cobaltite & Titanate Heterostructures

316 - Chris Leighton, University of Minnesota

8:00AM A14.00001 Orientation and Strain Dependence of the Magnetic Phase Separation at Perovskite Cobaltite Interfaces[1] , S. BOSE, M. SHARMA, M.A. TORIJA, CEMS, UMN, J. GAZQUEZ, M. VARELA, MST, ORNL and Univ Complutense, Madrid, H. AMBAYE, R. GOYETTE, V. LAUTER, Neutron Sciences Directorate, ORNL, M.R. FITZSIMMONS, LANSCE, LANL, J. SCHMITT, C. LEIGHTON, CEMS, UMN — We recently showed that the degraded magnetic and electronic properties in very thin STO(001)/$La_{1-x}Sr_xCoO_3$ films is due to a form of magnetic phase separation. This is primarily due to the strain driven accumulation of O vacancies near the interface. In this work we demonstrate how this understanding allows us to engineer these interfacial properties via crystallographic orientation and strain control. Using PNR, magnetometry and transport, we show how this degradation can be significantly mitigated by using LAO(001) and STO(110) substrates cf. STO(001). PNR on 400Å x=0.28 films reveals an interfacial layer with suppressed magnetism on all three substrates. However, while this layer is 150Å on STO(001), it extends at most to 30Å on LAO(001) and STO(110). Transport measurements on x=0.5 films show that at a thickness of $\sim$ 55Å, films on STO(110) and LAO(001) exhibit AMR whereas films on STO(001) are dominated by inter-cluster GMR. Finally, thickness dependent magnetometry shows that the magnetic order deteriorates more quickly on STO(001) than on LAO(001) and STO(110). Our work thus opens up a possible new route to tailor interfacial magneto-electronic properties in oxide heterostructures.

8:12AM A14.00002 Synthesis of Epitaxially Strained Brownmillerite Strontium Cobaltate ($SrCoO_{2.5}$) , ERIC JIN, MATTHEW MARSHALL, JOSEPH NGAI, CHARLES AHN, FRED WALKER, Yale University — Strontium cobaltate ($SrCoO_3$) is a perovskite oxide predicted to have metal-insulator transitions and magnetic phases induced by epitaxial strain. The related brownmillerite phase $SrCoO_{2.5}$ has a similar structure, but contains alternating planes of oxygen vacancies in the octahedral oxygen cages of the perovskite structure. We demonstrate epitaxial growth of $SrCoO_{2.5}$ on both $SrTiO_3$ and $LaAlO_3$ substrates by molecular beam epitaxy using RF oxygen plasma. X-ray diffraction measurements show finite thickness oscillations that are characteristic of smooth films, and half-order diffraction peaks that are representative of the brownmillerite phase. We observe a single tetragonal domain when the film is deposited on $SrTiO_3$ with the planes of oxygen vacancies parallel to the interface. When grown on $LaAlO_3$, the film contains multiple orthorhombic domains. We conclude that the observed domain structures for $SrCoO_3$ grown on $SrTiO_3$ and $LaAlO_3$ are due to ordering of the oxygen vacancies to reduce strain. We will also present strategies to increase the oxygen content to that of $SrCoO_3$.

8:24AM A14.00003 Magnetic Structure and Phase Separation in Epitaxial $SrCoO_x$ Thin Films[1] , F.J. RUECKERT, University of Connecticut, C. ABUGHAYADA, S.A. SABOK, Northern Illinois University, F. HE, Canadian Light Source, H. MOHOTTALA, University of Hartford, J.I. BUDNICK, W.A. HINES, University of Connecticut, B. DABROWSKI, Northern Illinois University, B.O. WELLS, University of Connecticut — Bulk $SrCoO_x$ separates into three distinct ferromagnetic phases as the oxygen content is increased from x = 2.75 to 3.0, corresponding to T_C = 165 K ($SrCoO_{2.75}$), T_C = 220 K ($SrCoO_{2.88}$), and T_C = 280 K ($SrCoO_{3.0}$). Over this composition, the lattice evolves smoothly and remains a single crystallographic phase. Using pulsed laser deposition and electrochemical oxidation, we have prepared epitaxial films of $SrCoO_x$ of varying thickness and orientation on $SiTiO_3$ substrates. While in polycrystalline samples intermediate oxygen concentrations show a two-phase magnetic behavior, 100nm thick (0 0 1) films remain single phase but still favor the same ferromagnetic transitions. Thicker, 150 nm (1 1 1) films also order at comparable T_C's, but again show two-phase behavior during deoxidation. Resonant x-ray diffraction on these samples reveals both commensurate and incommensurate ordering dependent on the oxidation state. This implies a charge or orbital ordering which may be influenced by finite size effects.

8:36AM A14.00004 Oxygen vacancy ordering in transition-metal-oxide $LaCoO_3$ films[1] , NEVEN BISKUP, JUAN SALAFRANCA, Univ. Complutense, Spain, VIRAT MEHTA, Univ. California, Berkeley, YURI SUZUKI, Univ. California, Berkeley and LBNL, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University, MARIA VARELA, Univ. Complutense, Spain — Oxygen vacancies in complex oxides affect the structure and the electronic and magnetic properties. Here we use atomically-resolved Z-contrast imaging, electron-energy-loss spectroscopy and densityfunctional calculations to demonstrate that ordered oxygen vacancies may act as the controlling degree of freedom for the structural, electronic, and magnetic properties of $LaCoO_3$ thin films. We find that epitaxial strain is released through the formation of O vacancy superlattices. The O vacancies donate excess electrons to the Co d-states, resulting in ferromagnetic ordering. The appearance of Peierls-like minigaps followed by strain relaxation triggers a nonlinear rupture of the energy bands, which explains the observed insulating behavior. We conclude that oxygen vacancy ordering constitutes a degree of freedom that can be used to engineer novel behavior in complex-oxide films.

8:48AM A14.00005 Local atomic and electronic structure of LaCoO3/SrTiO3 thin films by HAADF STEM and EELS[1] , ALBINA BORISEVICH, JAE HYUCK JANG, YOUNG-MIN KIM, Materials Science and Technology Division, Oak Ridge National Laboratory, LIANG QIAO, MICHAEL BIEGALSKI, Center for Nanophase Materials Scinces, Oak Ridge National Laboratory — For perovskite films with several competing functionalities, magnetic and electronic properties can be affected both by structural order parameters and chemical factors. For example, in LaCoO3 (LCO) thin films, magnetic and transport properties are strongly dependent on strain state and oxygen content. For this study, LCO thin films were deposited by pulsed laser deposition method with different thicknesses (2, 5, 15 unit cell and 20 nm thickness) on SrTiO3 substrate. X-ray photoelectron spectroscopy studies of the grown films have demonstrated that Co 3p edges shift up to 2 eV for 15 u.c. and 20 nm films, indicating possible presence of 2D electron gas. The structure of the 5 u.c and 15 u.c LCO films was examined. Atomic position mapping from STEM HAADF and BF images can reveal lattice parameter and octahedral tilt behavior with atomic resolution. BF STEM imaging showed that octahedral tilts were active in the 15 u.c. film but not in the 5 u.c. film. A complex pattern of O K fine structure evolution at the interface was observed; results of the deconvolution of different contributions to this behavior using advanced simulations, as well as data on oxygen vacancy mapping, will be presented.

9:00AM A14.00006 Dimensional control of cobalt spin state in oxide superlattices , DA WOON JEONG, CFI-CES, IBS, Seoul National University, W.S. CHOI, S. OKAMOTO, Oak Ridge National Laboratory, C.H. SOHN, H.J. PARK, CFI-CES, IBS, Seoul National University, J.-Y. KIM, Pohang Accelerator Laboratory, H.N. LEE, Oak Ridge National Laboratory, K.W. KIM, Chungbuk National University, S.J. MOON, Hanyang University, T.W. NOH, CFI-CES, IBS, Seoul National University — Perovskite cobalt oxide is a very intriguing system with various spin states owing to the delicate balance between crystal field splitting and Hund exchange energy. In this talk, we show that its spin state can be altered through dimensional control, enabled by digital synthesis of perovskite cobalt oxide superlattices. We employed a few unit cells of $LaCoO_3$ as an active magnetic layer, separated by $LaAlO_3$ spacer layer. High quality [($LaCoO_3$)n($LaAlO_3$)n]8 (n = 2, 6, and 10) superlattices were fabricated using pulsed laser epitaxy. Spectroscopic tools including x-ray absorption spectroscopy and optical spectroscopy revealed clear evolution of the electronic structure and resultant spin state by changing dimensionality. Specifically, the spin state changed from a high to a low spin state with a larger optical band gap, as the dimension reduced from 3D to 2D. Dynamic mean field calculation supported the critical role of dimensionality on the spin state and electronic structure of $LaCoO_3$.

9:12AM A14.00007 Emergent phenomena and magnetism in high-density electron gases in $SrTiO_3$, SUSANNE STEMMER, University of California, Santa Barbara — $GdTiO_3$/$SrTiO_3$ interfaces grown by molecular beam epitaxy exhibit mobile carrier densities that are remarkably well predicted by the electrostatic requirements of the compensation of the polar discontinuity at the interface. Carrier densities are ~3x10^{14} cm^{-2}, or ~0.5 electron per surface unit cell. By sandwiching few-unit-cell-thick $SrTiO_3$ layers between $GdTiO_3$, carrier concentrations in the $SrTiO_3$ approach densities under which on-site Coulomb interactions may appear. By changing the width of the quantum well, the 3D electron density can be varied, which allows for a systematic study of interaction effects. In this presentation, we discuss evidence for short-range Coulomb interactions, and associated phenomena, in ultrathin, confined the $SrTiO_3$ quantum wells containing extreme charge densities. We show that narrow $SrTiO_3$ quantum wells exhibit ferromagnetism at low temperatures, as evidenced by a hysteresis in the magnetoresistance. The Curie temperature scales with the thickness of the $SrTiO_3$ quantum well. We discuss evidence for on-site Mott-Hubbard-type correlation physics in the temperature-dependent transport in metallic quantum wells. With increasing 3D carrier densities we observe a correlation-induced mass enhancement, followed by a transition to a correlated insulator at the highest 3D densities. We also discuss the role of disorder in the insulating state. This work was done in collaboration with Pouya Moetakef, Clayton A. Jackson, Leon Balents, Jim Allen, Jimmy Williams and David Goldhaber-Gordon.

9:48AM A14.00008 Insulating room temperature ferromagnetic $SrTiO_3$, AGHAM POSADAS, CHANDRIMA MITRA, CHUNGWEI LIN, University of Texas at Austin, AJIT DHAMDERE, DAVID SMITH, Arizona State University, MAXIM TSOI, ALEX DEMKOV, University of Texas at Austin — We report the epitaxial growth of ferromagnetic insulating material based on $SrTiO_3$ using molecular beam epitaxy (MBE). $SrTi_{1-x}Co_xO_{3-\delta}$ films (x = 0.1 to 0.5) were grown on Si(100) substrates via a buffer layer of four unit cells of undoped $SrTiO_3$. The crystalline structure was characterized by reflection high energy electron diffraction, x-ray diffraction, and cross-section transmission electron microscopy. Robust room-temperature ferromagnetism is confirmed in samples with composition 30-40% Co. We also performed *in situ* x-ray photoelectron spectroscopy of the Sr, Co, Ti, and O core levels to determine stoichiometry and cobalt oxidation state. In all single phase samples, an oxygen vacancy concentration of approximately equal to the amount of Co substitution was measured (compensated doping). In order to elucidate the origin of ferromagnetism, we also performed first-principles calculations of $SrTiO_3$ simultaneously doped with Co and an oxygen vacancy. We find that such a configuration at concentrations of $\sim$ 25% can result in a ferromagnetic insulating state with high spin Co^{2+}. The ability to integrate an insulating ferromagnet on silicon in epitaxial form may potentially be useful for spin filtering and spin wave applications in the field of spintronics.

10:00AM A14.00009 Linear magnetoresistance in non-degenerately doped $SrTiO_3$[1] , ANAND BHATTACHARYA, Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory — I will present transport measurements on non-degenerately doped $n-SrTiO_3$ single crystals. The samples were doped by annealing at high temperatures in vacuum. The resistance decreases monotonically down to the lowest temperatures, for carrier densities as low as 3.85 x 10^{15}/cm^3. The magnetoresistance (MR) is found to be positive and linear at high fields, with R(9 T)/R(0 T) $>$ 28 at 2 K for the lowest doping levels measured. The magnitude of the MR decreases with increasing temperature, and with increased doping. I will discuss the data in light of various mechanisms for linear magnetoresistance in the context of $n-SrTiO_3$.

10:12AM A14.00010 The role of interface magnetic centers on the spin lifetime measured in doped SrTiO3 using Hanle technique , WEI HAN, XIN JIANG, IBM Almaden Research Center, ADAM KAJDOS, Materials Department, University of California, Santa Barbara, SEE-HUN YANG, IBM Almaden Research Center, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara, STUART PARKIN, IBM Almaden Research Center — Recently, the two dimensional electron gas that is formed at the surface of strontium titanate, SrTiO3 (STO), has attracted considerable attention, both concerning its origin as well as the many phenomena that it apparently displays: these include, gate tunable metallicity and superconductivity, and magnetic effects including Kondo scattering. Here, we report electrical injection and detection of spin currents in Nb doped STO substrates and La doped STO thin films using the Hanle technique and CoFe / MgO tunnel spin injectors. The spin lifetimes measured are on the order of 100 ps and vary little with temperature for temperatures varying from 10 K to 300 K, whereas the mobility of the STO has very strong temperature dependence. This suggests that the spin lifetime is limited by spin-dependent scattering at the MgO/STO interface, perhaps related to the formation of Ti3+ or other magnetic centers. Of considerable interest is that the spin lifetime decreases systematically with increasing dopant concentration, indicating that the number of magnetic centers at the interface increases with increasing dopant concentration. These results reveal a severe limitation of the Hanle technique for measuring spin lifetimes within the interior of the subject material.

10:24AM A14.00011 Magnetocapacitance in surface-reconstructed $LaMnO_3/SrTiO_3$ multilayers , RAINER SCHMIDT, JAVIER GARCIA-BARRIOCANAL, NORBERT NEMES, Universidad Complutense de Madrid, Fac. CC. Fisicas, GFMC, MAR GARCIA-HERNANDEZ, Instituto de Ciencia de Materiales de Madrid - Consejo Superior de Investigaciones Cientficas (ICMM-CSIC), CARLOS LEON, JACOBO SANTAMARIA, Universidad Complutense de Madrid, Fac. CC. Fisicas, GFMC — We report on large magnetocapacitance (MC) effects in $LaMnO_3/SrTiO_3$ multilayer structures. Frequency, temperature and magnetic field dependent dielectric spectroscopy was employed using in-plane and out-of-plane measurement set-ups to investigate multilayers of $LaMnO_3$ (15 u.c.) and $SrTiO_3$ (2 u.c.) with a repetition rate of 8: $(LMO\ 15/STO\ 2)_8$. Such multilayer structures have been identified previously to display an electron transfer across the epitaxial interface from LMO to STO, orbital reconstruction and a considerable Ti^{3+} magnetic moment near the LMO/STO interface [Garcia-Barriocanal et al. Adv. Mater. 22 (2010) p.627]. We demonstrate moderate in-plane magnetocapacitance (MC) of up to -5 % associated with an intrinsic magneto-electric coupling (MEC) effect originating from magnetic STO layers. Massive out-of-plane MC of up to -52 % was ascribed to current path changes due to magnetically active STO pin-holes and current path meandering.

10:36AM A14.00012 Enhanced Magnetism in $SrRuO_3$ Thin Film by $SrTiO_3$ Capping Monolayers , SEAN THOMAS, University of California, Irvine, BOUWE KUIPER, University of Twente, JEFF BOTIMER, ELLIOT PERSICO, University of California, Irvine, GERTJAN KOSTER, University of Twente, JING XIA, University of California, Irvine — Substrate induced mechanical strain is known to reduce the magnetism in itinerant ferromagnetic $SrRuO_3$ thin films. Here we show that monolayers of $SrTiO_3$ epitaxial capping film can be used to enhance the magnetism in ultra-thin $SrRuO_3$ films. For a device with a 6 monolayer thick $SrRuO_3$ film, a 2 monolayer thick $SrTiO_3$ capping layer can boost $SrRuO_3$'s magnetic Curie temperature by 15 Kelvin. Unlike thick substrates, the monolayers-thick $SrTiO_3$ capping layer can be patterned using standard lithography methods for making complex oxide electronic devices. We demonstrate a $SrRuO_3$ film device with regions of different Curie temperatures by patterning the $SrTiO_3$ capping layer.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A15 GMAG DMP: Focus Session: Exchange Bias and Magnetic Interfaces 317 - Igor Roshchin, Texas AM University

8:00AM A15.00001 Influence of magnetic annealing and interdiffusion on the exchange bias of CoFe/IrMn[1] , WALDEMAR MACEDO, LUIS FERNANDEZ-OUTON, MARIO ARAUJO FILHO, RAPHAEL ARAUJO, JOSE ARDISSON, Centro de Desenvolvimento da Tecnologia Nuclear - CDTN — Magnetic annealing is broadly used to set exchange bias (EB). The EB field depends on the magnetic field and the temperature at which the F/AF exchange interaction is set. Atomic interdiffusion is also expected to have strong influence on EB. For systems containing IrMn, different results have been reported regarding the effect of setting EB between 200 and 400 °C. We study the effect of atomic interdiffusion on the exchange bias of polycrystalline IrMn/(^{57}Fe+CoFe) multilayers due to the magnetic annealing between 225 and 500 °C. The samples have been prepared by magnetron sputtering, and ^{57}Fe probe layers (10 Å thick) were grown at the F/AF interface, and 1 nm and 2 nm above it, inside the CoFe layer. Depth-resolved ^{57}Fe conversion electron Mössbauer spectroscopy (CEMS) was used to quantify atomic interdiffusion, and vibrating sample magnetometry was used to monitor the variation of exchange bias and magnetisation. We found that interface sharpness is only affected above $\sim$350 °C. Three different stages for the setting of exchange bias can be inferred from our results. At temperatures $<$ 350 °C, no interdiffusion is observed and the F/AF exchange coupling establishes partial spin alignment of interfacial and bulk AF spins. At intermediate setting temperatures (350-450 °C) interfacial spin order is dominant over chemical intermixing effects, and both exchange field and coercivity increase up to 450 °C. Above 450 °C, severe chemical intermixing reduces significantly ($\sim$50%) the F/AF coupling.

8:12AM A15.00002 Controlling Exchange Bias in FeMn with Cu

, IGOR V. ROSHCHIN, DOGAN KAYA, PAVEL N. LAPA, Texas A&M University, PRIYANGA JAYATHILAKA, HILLARY KIRBY, CASEY W. MILLER, University of South Florida — One of the puzzles of exchange bias (EB) that remains unsolved is the origin and role of uncompensated magnetization (UM) in the antiferromagnet (AF). We offer a way of controlling the *intrinsic* EB in FeMn by growing it in contact with Cu. The multilayers of Ta(5 nm)/[Cu(5 nm)/FeMn($\mathbf{t}$)]$_{10}$/Ta(5 nm) with 5 nm $<\mathbf{t}<$15 nm are deposited by RF and DC magnetron sputtering on top of Si/SiO_2. The hysteresis loops at 10 K for field-cooled Cu/FeMn multilayers are EB-shifted, while the samples without Cu exhibit no EB. Unlike the "classical" EB observed at the interface of AF-ferromagnet (FM) bilayer systems, this EB is "intrinsic" to this system with no separate FM layer. The exchange bias field, $H_{\rm E}$ scales with the inverse thickness of FeMn. This fits Malozemoff's model,[1] where the thickness of the FM is replaced with the thickness of FeMn, which supports that the role of the FM is played by the UM which scales with the thickness of the FeMn film. Coercivity ($H_{\rm C}$) and $H_{\rm E}$ dependences on the FeMn thickness and temperature are similar to those for Cu/FeMn/Co samples. [2] This suggests that the *intrinsic* EB in Cu/FeMn may be determining the EB in AF-FM samples. The role of Cu in the intrinsic EB in FeMn will be discussed. Work is supported by TAMU-CONACyT Collaborative Research Program, and by NSF (at USF).

8:24AM A15.00003 Exchange Bias in Ferromagnetic/Antiferromagnetic/Ferromagnetic $Co/FeF_2/Co$ Trilayers[1]

, TRENT JOHNSON, DAVID LEDERMAN, West Virginia University, LEDERMAN GROUP TEAM — We have measured the magnetic properties of Co(20 nm)/FeF_2(2 nm)/Co(5 nm) trilayers grown on Al_2O_3 substrates via e-beam evaporation. The layers were polycrystalline and the samples were capped with 5 nm of Pd to avoid oxidation. The sample surface was very smooth, as indicated by AFM images where the underlying substrate's atomic terraces were visible, while the interface roughness parameters were on the order of 1 nm determined from x-ray reflectivity. After field-cooling to below the Néel temperature of FeF_2 in either 1 kOe and 5 kOe, magnetic hysteresis loops were measured as a function of temperature. We found that both layers have a negative exchange bias, with the exchange bias of the thinner layer larger than that of the thicker layer. In addition, the coercivity below the blocking temperature T_B of the thinner layer was significantly larger than that of the thick layer, even though the coercivity of the two layers is the same for $T > T_B$. The drastic difference in coercivities for $T < T_B$ illustrates the importance of the interface magnetic order on the reversal mechanism of the ferromagnet.

8:36AM A15.00004 Probing boundary magnetization through exchange bias in heterostructures with competing anisotropy[1]

, YI WANG, CHRISTIAN BINEK, Department of Physics and Astronomy, University of Nebraska-Lincoln — Cr_2O_3 (chromia) is a magnetoelectric antiferromagnet with a bulk T_N of 307 K. It has been utilized for electrically controlled exchange bias (EB) by taking advantage of voltage-controllable boundary magnetization (BM) occurring as a generic property in magnetoelectric single domain antiferromagnets.[2] In the perpendicular Cr_2O_3(0001)/CoPd EB system the EB-field shows an order parameter type T-dependence close to T_N reflecting the T-dependence of the BM. At about 150 K a decrease of the EB-field sets in with decreasing temperature suggesting canting of the BM. To evidence this mechanism we use EB as a probe. Specifically, we investigate EB in Permalloy(5nm)/Cr_2O_3 (0001)(100nm) with Permalloy and chromia having competing anisotropies. We measure easy axis magnetic hysteresis loops via longitudinal magneto-optical Kerr effect for various temperatures after perpendicular and in-plane magnetic field-cooling. The T-dependence of the EB field supports the canting mechanism. In addition to the all thin film EB system, we explore a Permalloy(10nm)/Cr_2O_3(0001 single crystal) heterostructure where magnetoelectric annealing allows selecting Cr_2O_3 single domain states. Here the effect of T-dependent canting of the BM is compared with findings in the complementary perpendicular EB system.

8:48AM A15.00005 Positive exchange bias in thin film multilayers produced with nano-oxide layer

, BYONG SUN CHUN, Korea Research Institute of Standards and Science, MOHAMED ABID, Ecole Polytechnique Federale de Lausanne/IPMC, HAN-CHUN WU, CRANN, Trinity College, IN CHANG CHU, Global EMI/EMC team, 3M Korea Innovation Center, CHANYONG HWANG, Korea Research Institute of Standards and Science — We report a positive exchange bias in thin film multilayers produced with nano-oxide layer.The positive exchange bias, obtained for our system results from an antiferromagnetic coupling between the ferromagnetic CoFe and the antiferromagnetic CoO layers, which spontaneously from on top of the nano-oxide layer. The shift in the hysteresis loop along the direction of the cooling field and the change in the sign of exchange bias are evidence of antiferromagnetic interfacial exchange coupling between the CoO and CoFe layers. Our calculation indicates that uncompensated oxygen moments in the nano-oxide layer results in antiferromagnetic interfacial exchange coupling between the CoO and CoFe layers. One of the interesting features observed with our system in that it displays the positive exchange bias even above the bulk Neel temperature of CoO

9:00AM A15.00006 Isothermal electric field-tuning of Exchange bias training in $Cr_2O_3/PdCo$[1]

, WILL ECHTENKAMP, CHRISTIAN BINEK, University of Nebraska-Lincoln — Voltage-controlled exchange bias (EB) is investigated in a Cr_2O_3/PdCo EB heterosystem where a ferromagnetic and perpendicular anisotropic Pd/Co multilayer has been deposited on a (0001) Cr_2O_3 (chromia) single crystal. The EB of the system arises from chromia's electrically controllable boundary magnetization (BM) which is switched isothermally and at room temperature by magnetoelectric means [1]. The BM couples to the bulk AF order parameter and follows the latter during switching. In the work reported here, we electrically and isothermally tune chromia into distinct AF multi-domain states. As a result, exchange bias training, which originates from triggered rearrangements of the AF domain state of the pinning system during consecutively cycled hysteresis loops, can be tuned in a controlled manner between zero and sizable effects. We quantify the training effect through best fits of our Landau-Khalatnikov analytic expression [2] to the EB vs loop number. The electric field dependence of the fitting parameters is interpreted in terms of the hysteretic E-field dependence of the AF order parameter.

9:12AM A15.00007 Depth profiling of interfacial spin complexities in magnetic heterostructures[1] , SUJOY ROY, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Attentively restrained interfaces or superlattices between two materials can lead to emergent functionalities not shown by either constituents in their bulk form. Direct quantitative investigation of spatio-temporal correlations of magnetic and electronic properties of such interfaces is crucial in controlling and tailoring the close proximity of competing energy landscape that naturally exist in these systems. Due to the smallness and buried nature of the magnetization, characterizing these materials at the appropriate length scale is of considerable challenge. In this talk I will give examples from a variety of systems where the unique sensitivity of soft x-ray beams in reflection geometry have been exploited to obtain a quantitative description of the complex magneto-chemical depth profile across the interface between ferromagnetic (F) and antiferromagnetic (AF) thin films. In exchanges bias Co/FeF_2 heterostructures we have found antiferromagnetic coupling across the interface with the net magnetization having a twisted "fan-like" structure near the F/AF interface. For Py/CoO we observed a redox reaction driven novel interfacial layer that has magnetic properties very different from bulk. We found that 10% of the net spins in this layer get pinned antiparallel to the cooling magnetic field at low temperatures. In complex oxide $BiFeO_3$-$La_{0.7}Sr_{0.3}MnO_3$ we have obtained direct experimental evidence of transitory layers, ionic rearrangements and depleted magnetism at the $BiFeO_3$-$La_{0.7}Sr_{0.3}MnO_3$ interface. Our examples show that interface-selective probing of magnetism in thin film heterostructures can provide vital understanding needed for rational design of future nanoelectronic devices.

[1]Work is supported by U.S DOE.

9:48AM A15.00008 Temperature Dependence of Current Induced Magnetic Domain Wall Motion in a Multilayered Co/Ni Nanowire with MgO Cap , KOHEI UEDA, RYO HIRAMATSU, KABJIN KIM, ICR, Kyoto University, DAICHI CHIBA, ICR, Kyoto University/PRESTO, JST, TAKAHIRO MORIYAMA, ICR, Kyoto University, HIRONOBU TANIGAWA, EIJI KARIYADA, TETSUHIRO SUZUKI, RENESAS Electronics Corp., YOSHINOBU NAKATANI, University of Electro-communication, TERUO ONO, ICR, Kyoto University — Current-induced magnetic domain wall motion (CIDWM) has been investigated not only for the fundamental physics but also for its potential application for nonvolatile magnetic random access memory. Our group reported that adiabatic spin transfer torque (STT) dominates the DW motion in nanowires made of a perpendicularly magnetized Co/Ni multilayer with symmetrical top and bottom non-magnetic layers (Ta/Pt and Pt/Ta). Recently, new aspect of the DW motion was reported that DW moves against electron flow direction in asymmetric AlO/Co/Pt system, which is in contrast to STT theory that predicts the DW motion along electron flow direction. We found, in a nanowire made of an Co/Ni multilayer with asymmetric top (MgO) and bottom (Pt/Ta) layers, that the DW moves against electron flow direction as reported in AlO/Co/Pt system. We also investigated the temperature dependences of the threshold current density for DW displacement (Jth). It was found that Jth increases with decreasing device temperature whereas it is almost independent of temperature in a symmetric Co/Ni system, suggesting that the observed DW motion was not simply dominated by the adiabatic STT brought by the electron flow in the Co/Ni multilayer.

10:00AM A15.00009 Electrical Probing of Magnetic Phase Transition and Domain Wall Motion in Single-Crystalline Mn_5Ge_3 Nanowire[1] , JIANSHI TANG, CHIU-YEN WANG, KANG L. WANG, Device Research Laboratory, Department of Electrical Engineering, University of California, Los Angeles, California, 90095, USA, LIH-JUANN CHEN, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, 30013, Republic of China — We studied the magnetic phase transition and domain wall motion in single-crystalline Mn_5Ge_3 nanowires fabricated by thermally germaniding Ge nanowires with Mn contacts. The R-T curve showed a clear slope change near 300 K accompanied by a magnetic phase transition from ferro- to para-magnetism. Near this phase transition, the critical behavior was characterized by a power-law relation with a critical exponent of about 0.07. Besides, a cusp revealed in the dR/dT curve at about 67 K was attributed to a possible magnetic transition between non-collinear and collinear ferromagnetic states. Furthermore, temperature-dependent magneto-transport measurements demonstrated a hysteretic, symmetric and stepwise axial magnetoresistance. The interesting features of abrupt jumps indicated the presence of multiple domain walls in the Mn_5Ge_3 nanowire and the annihilation of domain walls driven by the magnetic field. The fitting on the temperature-dependent depinning fields yielded an energy barrier of 0.166 eV based on the Kurkijarvi model describing the domain wall depinning as thermally assisted escape from a single energy barrier.

[1]The work was supported in part by Western Institute of Nanoelectronics.

10:12AM A15.00010 Topological classification of domain walls in a cylindrical nanowire[1] , SE KWON KIM, CHRISTOPHER MOGNI, OLEG TCHERNYSHYOV, The Johns Hopkins University — We classify possible configurations of domain walls in a cylindrical nanowire [1-3] using topology. Dipolar interactions induce effective shape anisotropy so that magnetization tends to be tangential to the surface locally and is parallel to the axis of the wire in the ground states. Topological defects in the bulk are Bloch points with integer skyrmion numbers [second homotopy group $\pi_2(S^2)$]. The surface anisotropy gives rise to surface defects (boojums) with integer vorticity [first homotopy group $\pi_1(S^1)$] and half-integer skyrmion number [relative second homotopy group $\pi_2(S^2, S^1)$]. These defects are weakly bound by the easy-axis anisotropy into composite domain walls. Thus transformations and mergers of domain walls are constrained by the topological conservation laws. Long-lived textures left behind after annihilation of domain walls are classified by the third homotopy group $\pi_3(S^2)$.

10:24AM A15.00011 Domain wall remote pinning in magnetic nano wires , DAN READ, Cardiff University, JORGE MIGUEL, FRANCESCO MACCHEROZZI, STUART CAVILL, SARNJEET DHESI, Diamond Light Source, CARDIFF UNIVERSITY COLLABORATION, DIAMOND LIGHT SOURCE COLLABORATION — In the current race for information storage media with ever increasing density the position of magnetic domain walls, the region in a magnetic system where the local magnetization continually rotates its direction between adjacent magnetic domains, is one of the most promising routes for future storage media devices. Information storage requires ultrafast read-out and writing operations, but domain walls need to be pinned so that the information is safely stored in the long term. Here we investigate the use of remote magnetostatic charges to trap domain walls. By using X-ray photoelectron emission microscopy we have followed the position of domain walls of opposite charge being pinned or repelled by pinning potentials of increasing strength. Micromagnetic simulations show an excellent agreement with the experimental results. We demonstrate the attractive or repulsive character of the interaction between domain wall and trap depending upon the sign of their magnetic charges. These quasi-static experiments are the antecedent to ultrafast time-resolved XMCD-PEEM experiments where the spin-transfer torque effect will be studied dynamically by applying picosecond-long current pulses across the magnetic nanowire.

Session A16 GMAG DMP: Focus Session: Spin-Dependent Physics in Organic Compounds 318

- Christoph Boehme, University of Utah

8:00AM A16.00001 Competing Mechanisms in Organic Magnetoresistance

, BERT KOOPMANS, Eindhoven University of Technology, Eindhoven, The Netherlands — A surprisingly large "organic magnetoresistance" (OMAR) has been found in both polymers and small molecule organic semiconductors at relatively small applied magnetic fields ($\sim$ 5 mT) and at room temperature. Unlike spin-injection devices, where the occurrence of a finite *spin polarization* of the current is essential for measuring a finite magnetoresistance, OMAR is generally considered to be due to *spin correlations* between spin carrying particles in the organic material. Although the microscopic mechanisms of hyperfine field induced spin mixing are relatively well understood, it is still intensively debated which particles are involved and how they can affect the current in such a drastic manner. In this presentation recent developments and new insights as to the underlying physics are discussed. Quantitative models will be introduced, based on different pairs of particles and mechanisms, and giving rise to effects at a variety of field scales. It will be discussed how specific device physics causes a non-trivial relation between microscopic spin-dependent reactions and macroscopic device behaviour. Finally, it will be shown how comprehensive studies on especially engineered organic systems, including polymer-fullerene blends and molecular doping, can be used to pinpoint the relevance of different mechanisms in the complementary regimes. The experimentally observed linewidth, sign and amplitude of both "high-field" (>100 mT) and "low-field" ($\sim$ 5 mT) effects, as well as their bias voltage dependence display very pronounced features as a function of fullerene doping. They provide unique fingerprints for which mechanism is of relevance. After careful analysis, this allows for identification of three earlier proposed mechanisms, involving exciton-charge, electron-hole and bipolaron (polarons of like charge) reactions. Present activities are aiming at using this insight for tailoring OMAR response by design.

8:36AM A16.00002 Recent Advance in Organic Spintronics and Magnetic Field Effect[1]

, Z. VALY VARDENY, University of Utah — In this talk several important advances in the field of Organic Spintronics and magnetic field effect (MFE) of organic films and optoelectronic devices that have occurred during the past two years from the Utah group will be surveyed and discussed. (i) Organic Spintronics: We demonstrated spin organic light emitting diode (spin-OLED) using two FM injecting electrodes, where the electroluminescence depends on the mutual orientation of the electrode magnetization directions [1]. This development has opened up research studies into organic spin-valves (OSV) in the space-charge limited current regime. (ii) Magnetic field effect: We demonstrated that the photoinduced absorption spectrum in organic *films* (where current is not involved) show pronounced MFE [2]. This unravels the underlying mechanism of the MFE in organic devices, to be more in agreement with the field of MFE in Biochemistry. (iii) Spin effects in organic optoelectronic devices: We demonstrated that certain spin 1/2 radical additives to donor-acceptor blends substantially enhance the power conversion efficiency of organic photovoltaic (OPV) solar cells [3]. This effect shows that studies of spin response and MFE in OPV devices are promising.

9:12AM A16.00003 Spin-dependent charge carrier recombination in PCBM

, HIROKI MORISHITA, WILLIAM J. BAKER, DAVID P. WATERS, RACHEL BAARDA, University of Utah, JOHN M. LUPTON, University of Regensburg, CHRISTOPH BOEHME, University of Utah, UTAH SPIN ELECTRONICS GROUP COLLABORATION, LUPTON GROUP COLLABORATION — We present room temperature pulsed electrically detected magnetic resonance (pEDMR) measurements on [6,6]-phenyl-C_{61}-butyric acid methyl ester (PCBM) (electron acceptor) thin film unipolar and bipolar devices. Our study aimed at identifying the dominating spin-dependent transport and recombination processes therein. Experimentally, the devices were operated under a constant positive bias, and the resultant transient current response was then monitored after the application of a short resonant microwave pulse excitation. The measurements did not reveal any observable signal for unipolar electron devices which suggests that spin-dependent transport mechanisms are not dominant in PCBM. However, under bipolar injection, at least two pronounced spin-dependent signals were detected whose magnitudes increased as the devices degraded upon exposure to air. Electrical detection of spin-Rabi beat oscillation revealed that one of these two signals is due to weakly coupled pairs of spins with s=1/2. We therefore attribute this signal to electron-hole recombination. This observation shows that while PCBM is a poor hole conductor, hole injection can be significant.

9:24AM A16.00004 Robust Absolute Magnetometry with Organic Thin-Film Devices

, DAVID P. WATERS, WILLIAM J. BAKER, KAPIL AMBAL, RACHEL BAARDA, HIROKI MORISHITA, KIPP VAN SCHOOTEN, University of Utah, DANE R. MCCAMEY, University of Sydney, JOHN M. LUPTON, Universität Regensburg, CHRISTOPH BOEHME, University of Utah — Magnetometers based on organic thin film materials have attracted considerable interest in recent years as they can be manufactured at very low cost and on flexible substrates. In spite of these advantages, the technological relevance of such magnetoresistive sensors is limited due to their narrow magnetic field ranges ($\sim$30mT) and the continuous calibration required to compensate temperature fluctuations and materials degradation. Conversely, magnetic resonance based sensors, which utilize fundamental physical relationships for extremely precise measurements of fields, are usually large and expensive. This presentation will discuss an organic magnetic resonance based magnetometer [1], employing spin-dependent electronic transitions in an organic diode, which combines the low-cost thin-film fabrication and integration properties of organic electronics with the precision of a magnetic resonance based sensor.

9:36AM A16.00005 Organic magnetoresistance near saturation: mesoscopic effects in small devices[1]

, ROBERT ROUNDY, ZEEV VARDENY, MIKHAIL RAIKH, University of Utah — In organic light emitting diodes with small area the current may be dominated by a finite number, N of sites in which the electron-hole recombination occurs. As a result, averaging over the hyperfine magnetic fields, $\mathbf{b}_h$, that are generated in these sites by the environment nuclei is incomplete. This creates a random (*mesoscopic*) current component, $\delta I(\mathbf{B})$, at field $\mathbf{B}$ having relative magnitude $\sim N^{-1/2}$. We demonstrate that mesoscopic fluctuations develop at fields $|\mathbf{B}| \gg |\mathbf{b}_h|$, where the average magnetoresistance is near saturation. These fluctuations originate from the slow beating between S and T_0 states of the recombining e-h spin pair-partners. We identify the most relevant processes responsible for the current fluctuations as due to anomalously slow beatings that develop in sparse e-h polaron pairs at sites for which the $\mathbf{b}_h$ projections on the external field direction almost coincide. To find the characteristic period $\Delta\mathbf{B}$ of the fluctuations, we calculate the correlator $K(\mathbf{B}, \Delta\mathbf{B}) = \langle \delta I\left(\mathbf{B} - \Delta\mathbf{B}\right) \delta I\left(\mathbf{B} + \Delta\mathbf{B}\right) \rangle$.

9:48AM A16.00006 Photocontrolled spin polarization at hybrid organic-ferromagnetic interfaces[1] , YAN WANG, HAI-PING CHENG, Dept. of Physics and Quantum Theory Project, University of Florida — We report a first-principles study of magnetic properties at an organic-ferromagnetic interface by placing light-switchable azobenzene molecules on a Fe/W(110) surface. Our calculations clearly demonstrate that the magnetic properties of the hybrid interface, such as the local magnetic moment and spin polarization, change significantly as the azobenzene molecule switches reversibly from the trans to the cis form. The molecule-surface interaction, which determines the feasibility of photo-switching of the azobenzene on the surface, can be altered by chemical functionalization of the molecule. Specifically, we find that substitution of the H atoms with electronegative F atoms substantially reduces the binding energies of the molecule on the Fe surface. This study suggests a new way to manipulate magnetism by application of light at organic-ferromagnetic hybrid interfaces.

10:00AM A16.00007 The Effects of Fringe Fields on Organic Magnetoresistance[1] , NICHOLAS HARMON, Department of Physics and Astronomy, University of Iowa, FERRAN MACIÀ, Deptarment of Physics, New York University, FUJIAN WANG, MARKUS WOHLGENANNT, Department of Physics and Astronomy, University of Iowa, ANDREW KENT, Deptarment of Physics, New York University, MICHAEL FLATTÉ, Department of Physics and Astronomy, University of Iowa — The importance of random hyperfine fields is now widely acknowledged as a vital ingredient for the phenomena of organic magnetoresistance (OMAR). Recent experiments (Phys. Rev. X 2 021013 (2012)) have shown that another type of random field - fringe fields due to a nearby ferromagnet - can also dramatically affect magnetoconductivity. A theoretical analysis of the fringe field OMAR is challenging due to the different properties of the fringe fields when compared to the hyperfine fields. For instance, the range of fringe field strengths is 1-2 orders of magnitude larger than that of the hyperfine couplings. The correlation length between fringe fields is also larger by the same degree. We use a recent theory of OMAR that is well-suited to numerically calculate the magnetoresistance with both hyperfine and fringe fields present. We find agreement with key features of experimental fringe-field magnetoresistance dependences on applied magnetic field, including the field values of extrema of the magnetoresistance, the region of large magnetoresistance effects from the fringe fields, and the sign of the effect.

10:12AM A16.00008 Using photoexcited triplet states to probe small-molecule endohedral fullerenes by ESR , VASILEIA FILIDOU, London Centre for Nanotechnology, University College London, London WC1H, UK, SALVATORE MAMONE, School of Chemistry, University of Southampton, SO17 1BJ, UK, ALESSANDRO BAGNO, FEDERICO RASTRELLI, Dipartimento di Scienze Chimiche, Universita di Padova, via Marzolo, 1 -35131, Italy, YASUJIRO MURATA, KOICHI KOMATSU, Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan, XUEGONG LEI, YONGJUN LI, NICHOLAS J. TURRO, Department of Chemistry, Columbia University, New York, New York 10027, US, MALCOLM H. LEVITT, School of Chemistry, University of Southampton, SO17 1BJ, UK, JOHN J.L. MORTON, London Centre for Nanotechnology, University College London, London WC1H, UK — Ortho to para conversion of molecular hydrogen H_2 can be catalyzed by the use of a coupled paramagnet such as a fullerene in its triplet state. The recently synthesized endohedral fullerenes $H_2@C_{60}$ and $H_2@C_{70}$ were photoexcited to their long lived triplet state (S= 1) and probed by electron spin resonance (ESR) and electron nuclear double resonance (ENDOR) spectroscopic techniques. With these techniques we characterized both spin systems by extracting the hyperfine interaction the kinetic parameters of the triplet state and the spin relaxation times. The observed variations of the linewidths and the lineshape are discussed in the context of a dynamic Jahn-Teller effect. Irradiation of the $H_2@C_{70}$ at different temperatures reveals that the fullerene triplet state can serve as a spin catalyst for ortho to para interconversion while for the triplet $H_2@C_{60}$ no appreciable interconversion is observed

10:24AM A16.00009 Electron Spin Relaxation Dynamics in Single-Walled Carbon Nanotubes[1] , WILLIAM RICE, Los Alamos National Laboratory, Los Alamos, NM USA 87545, RALPH WEBER, Bruker BioSpin Corp., Billerica, MA USA 01821, PAVEL NIKOLAEV, SIVARAM AREPALLI, Dept. of Energy Science, Sungkyunkwan University, Suwon 440-746, South Korea, VLADIMIR BURKA, AH-LIM TSAI, University of Texas Medical School, Houston, TX USA 77030, JUNICHIRO KONO, Dept. of Electrical and Computer Engineering, Rice University, Houston, TX 77005 — We have measured temperature-dependent electron spin resonance (ESR) in an ensemble of single-walled carbon nanotubes. From the linewidths of these traces, we clearly observe that the spin-spin dephasing time, T_2, decreases by over a factor of two when temperature, T, is lowered from 300 K to 3 K, a phenomenon we attribute to motional narrowing. We fit the temperature dependence of T_2 with a hopping model and obtain a spin hopping frequency of 285 GHz. At selected temperatures below 100 K, we performed microwave power-dependent scans to investigate the saturation behavior of the ESR signal. A homogenously broadened two-level model fit the saturation data well, which allowed us to extract the spin-lattice relaxation times, T_1, for the investigated temperature range. We observed that the spin-lattice relaxation rate,$1/T_1$, is proportional to T from 100 K to 3 K, suggesting that the relaxation occurs via phonon emission. Last, we show that the Dysonian lineshape asymmetry, which is roughly proportional to the conductivity, follows a three-dimensional variable-range hopping behavior from 3 K to 20 K, from which we estimate a spin hopping localization length of 100 nm.

10:36AM A16.00010 Mechanical read out of a single electron spin in a carbon nanotube , GUIDO BURKARD, HENG WANG, PHILIPP STRUCK, University of Konstanz — The spin of a single electron in a suspended carbon nanotube can be read out by using its coupling to the nano-mechanical motion of the nanotube. To show this, we consider a single electron confined within a quantum dot formed by the suspended carbon nanotube. The spin-orbit interaction induces a coupling between the spin and one of the bending modes of the suspended part of the nanotube [1]. We simulate the response of the system to the external driving with a Jaynes-Cummings model by solving the quantum master equation. Using parameters comparable to those used in recent experiments, we show how information of the spin state of the system can be acquired by measuring its mechanical motion [2]. The mechanical motion can be detected by observing the current through a nearby charge detector.

Session A17 DMP GMAG: Focus Session: Multiferroic Skyrmions

319 - Nicholas Butch, Lawrence Livermore National Laboratory

8:00AM A17.00001 Simulation on doping dependent phase transition in MnSi by Monte Carlo method , JHIH-AN YANG, DMITRY REZNIK, University of Colorado at Boulder — Recently, the skyrmion lattice has been found in the A phase of the itinerant helimagnet MnSi by small angle neutron scattering and the magnetic analogue of blue phases has been reported to explain a number of puzzling features of MnSi. Here we use a different approach based on Monte Carlo methods, showing the thermal behavior around transition temperatures in doped systems under the simplest Dzyaloshinsky-Moriya nearest-neighbor interactions. Interestingly, the transition temperature decreases with increasing doping concentrations, which is consistent with the experimental observations. We also show how the topological order parameter changes with temperature and its relation with the specific heat and thermal fluctuations.

8:12AM A17.00002 Observation of coherent helimagnons in the Skyrmionic helimagnets[1] , JAKE KORALEK, Lawrence Berkeley National Lab, DENNIS MEIER, JAMES HINTON, University of California, Berkeley, ANDREAS BAUER, Technische Universität München, SID PARAMESWARAN, University of California, Berkeley, ASHVIN VISHWANATH, University of California, Berkeley, and Lawrence Berkeley National Lab, CHRISTIAN PFLEIDERER, Technische Universität München, ROOMAMOORTHY RAMESH, University of California, Berkeley, and Lawrence Berkeley National Lab, BOB SCHOENLEIN, Lawrence Berkeley National Lab, JOE ORENSTEIN, University of California, Berkeley, and Lawrence Berkeley National Lab — In MnSi and $Fe_{1-x}Co_xSi$ the interplay between the spin-orbit and exchange interactions leads to a variety of helical magnetically ordered states. Perhaps the most interesting of these is the Skyrmion lattice phase in which the spins form topologically-stabilized vortices which decouple from the host lattice to form their own lattice structure. We use pump-probe reflectivity and Kerr rotation to study the dynamics in these materials, observing coherent collective excitations unique to helimagnets known as helimagnons. Monitoring helimagnon decay in the time-domain directly yields the Gilbert damping parameter in these systems.

8:24AM A17.00003 The Chiral Hall Effect in the Presence of Impurities: a Study on $Mn_{1-x}Fe_xSi$[1] , BENJAMIN CHAPMAN, University of Colorado, Boulder, THOMAS WOLF, Karlsruher Institute for Technology, MINHYEA LEE, University of Colorado, Boulder — Recently much attention has been paid to the itinerant ferromagnet MnSi. This is due largely to the emergence of an exotic topological object–the so-called skyrmion, which forms a lattice near T_c at ambient pressure. Past efforts to understand this configuration have observed its response to various perturbations, including temperature gradients, strong electric fields, and hydrostatic pressure. Here, we present Hall effect measurements on single crystals of Fe doped MnSi at ambient pressure, exploring how impurities interact with electronic charge and the long range magnetic order in this peculiar magnetic phase. In pure MnSi, the chiral Hall signal below T_c is significantly enhanced as T_c is suppressed by application of pressure. With chemical doping, though, the chiral Hall signal is substantially weakened, appearing in a narrower window of temperature and magnetic field relative to pure MnSi under pressure with comparable T_c. Interestingly, however, and in contrast to hall data taken under pressure, the chiral contribution in iron doped MnSi is found to have opposite sign as the anomalous Hall effect. We will discuss the implications of this Hall effect result and compare it to measurements on pure MnSi under pressure.

8:36AM A17.00004 Observation of Skyrmions in a Multiferroic Material , SHINICHIRO SEKI, Department of Applied Physics, University of Tokyo — Magnetic skyrmion is a topologically stable particle-like object, which appears as nanometer-scale vortex-like spin texture in a chiral-lattice magnet [1]. In metallic materials (MnSi, FeGe, $Fe_{1-x}Co_xSi$ etc), electrons moving through skyrmion spin texture gain a nontrivial quantum Berry phase, which provides topological force to the underlying spin texture and enables the current-induced manipulation of magnetic skyrmion [2]. Such electric controllability, in addition to the particle-like nature, is a promising advantage for potential spintronic device applications. Recently, we newly discovered that skyrmions appear also in an insulating chiral-lattice magnet Cu_2OSeO_3 [3,4]. We find that the skyrmions in insulator can magnetically induce electric polarization through the relativistic spin-orbit interaction, which implies possible manipulation of the skyrmion by external electric field without loss of joule heating [5]. The present finding of multiferroic skyrmion may pave a new route toward the engineering of novel magnetoelectric devices with high energy efficiency. In this talk, the latest experimental and theoretical results on the dynamical aspect of magnetoelectric skyrmions will also be discussed.

9:12AM A17.00005 Inertia and chiral edge modes of a skyrmion magnetic bubble[1] , IMAM MAKHFUDZ, Johns Hopkins University, BENJAMIN KRUEGER, University of Hamburg, OLEG TCHERNYSHYOV, Johns Hopkins University — Dynamics of topological defects is a topic of longstanding interest in magnetism. The attention to it stems from rich basic physics as well as from its connection to technological applications. The dynamics of a vortex in a thin-film ferromagnet resembles the motion of a charged massless particle in a uniform magnetic field. Similar dynamics is expected for other magnetic textures with a nonzero skyrmion number. However, recent numerical simulations revealed that skyrmion magnetic bubbles show significant deviations from this model. In this talk we present the derivation of the correct dynamical model of a skyrmion magnetic bubble. We first introduce our model phenomenologically and then derive it from the standard theory of a thin-film ferromagnet. This allows us to characterize not only the center-of-mass motion of the bubble but also the dynamics of its shape within the same framework.We show that a skyrmion bubble possesses inertia and derive its mass from the standard theory of a thin-film ferromagnet. Besides center-of-mass motion, other low energy modes are waves on the edge of the bubble traveling with different speeds in opposite directions.

9:24AM A17.00006 Universal current-velocity relation of skyrmion motion in chiral magnets , JUNICHI IWASAKI, MASAHITO MOCHIZUKI, NAOTO NAGAOSA, Department of Applied Physics, The University of Tokyo — Current-driven motion of the magnetic domain wall requires large critical current density $j_c \sim 10^9 - 10^{12}$ A/m^2, at which the joule heating is a serious problem. The skyrmions recently discovered in chiral magnets, on the other hand, have much smaller critical current of $j_c \sim 10^5 - 10^6$ A/m^2. We present a numerical simulation of the Landau-Lifshitz-Gilbert equation, which reveals a remarkably robust and universal current-velocity relation of the slyrmion motion driven by the spin transfer torque unaffected by either impurities or nonadiabatic effect in sharp contrast to the case of domain wall or spin helix (HL). Simulation results are analyzed using a theory based on Thiele's equation, and it is concluded that this surprising behavior is due to the Magnus force and flexible shape-deformation of individual skyrmions and skyrmion crystal (SkX), which enable them to avoid pinning centers and then weaken the net pinning force. Dynamical deformation of SkX leads to the fluctuation of Bragg peak with large amplitude, which can be detected by the recent neutron-scattering experiment.

9:36AM A17.00007 Cooperative organization of local and itinerant moments in antiferromagnetic GdSi , YEJUN FENG, JASPER VAN WEZEL, J.W. KIM, Y. REN, P.B. LITTLEWOOD, Argonne National Laboratory, B. MIHAILA, R.K. SCHULZE, Los Alamos National Laboratory, J.-Q. YAN, Univ. Tennessee and ORNL, JIYANG WANG, NAYOON WOO, A. PALMER, D.M. SILEVITCH, T.F. ROSENBAUM, Univ. of Chicago — With strong correlations and reduced dimensionality, spin and charge instabilities emerge in a broad range of materials. Direct magnetic exchange, interactions mediated by the conduction electrons, and coupling to the lattice are all familiar drivers of density waves. In materials which have significant localized and itinerant spins, it is not obvious which will induce order. We combine transport, magnetic diffraction, and photoemission studies with band structure calculations to elucidate the nature of successive antiferromagnetic transitions in GdSi. GdSi has both sizable local moments and a partially-nested Fermi surface of itinerant spins, without confounding contributions from orbital effects. We propose a new route to incommensurate order, based on a cooperative feedback mechanism between localized Gd 4f and itinerant Gd 5d electronic spins. The nested Fermi surface of the itinerant electrons induces a strong interaction between local moments at the nesting vector, while the presence of ordered local moments in turn provides the necessary coupling strength for a spin density wave to form among the itinerant electrons. This mechanism echoes the cooperative interactions between itinerant electrons and localized ionic cores in charge density wave materials, and should be germane across a spectrum of transition metal and rare earth intermetallic compounds.

9:48AM A17.00008 Magnetic Phase Diagram of the Binary Intermetallic GdSi , D.M. SILEVITCH, University of Chicago, YEJUN FENG, Argonne National Laboratory, J.-Q. YAN, Univ. Tennessee and ORNL, JIYANG WANG, NAYOON WOO, T.F. ROSENBAUM, University of Chicago — The magnetic phase diagram of the binary intermetallic GdSi is investigated via magnetotransport and magnetization measurements along all three principal crystal axes. At zero applied field, two distinct phase transitions are observed at 53 and 54.7 K, corresponding to a spin flip and Neel transition, respectively. An additional ordered antiferromagnetic state appears for magnetic fields applied in the a-c plane, transitioning to a ferromagnetic ground state at $H \sim 20$ T. Although Gd ions are well characterized by local spin-only moments, and the magnetic anisotropy is small in this system, the additional antiferromagnetic ordering transition is observed to be considerably softer along c than along a. The interplay between this complex magnetic phase diagram, the band structure, and quantum effects will be discussed.

10:00AM A17.00009 ABSTRACT WITHDRAWN –

10:12AM A17.00010 Near room temperature helical magnetism in Fe(1-x)Cr(x)Ge[1] , YUEN YIU, NIRMAL GHIMIRE, Department of Physics and Astronomy, University of Tennessee, MICHAEL MCGUIRE, Materials Science and Technology Division, Oak Ridge National Laboratory, ASHFIA HUQ, Chemical and Engineering Materials Division, Neutron Sciences Directorate, Oak Ridge National Laboratory, DAVID MANDRUS, Materials Science and Engineering, University of Tennessee, STEPHEN NAGLER, Quantum Condensed Matter Division, Oak Ridge National Laboratory — Helical magnetic structures in chiral metallic magnets have attracted much interest recently because of the observation of complex spin textures, for example the skyrmion lattice. FeGe is a known B20 spiral ferromagnet that orders at the relatively high temperature of 280K with a helical modulation period of 700 angstroms, which propagates along either the [100] or [111] directions depending on temperature. Here we report a study on the evolution of helimagnetism as a function of Cr doping on a series of Fe(1-x)Cr(x)Ge samples with x = 0.03 to 1. Magnetic susceptibility measurements have shown that the ferromagnetic-like transition associated with helimagnetism in FeGe is suppressed around x = 0.4.

[1]This work is sponsored by the US DOE Basic Energy Sciences.

10:24AM A17.00011 Ferromagnetic ordering and halfmetallic state in a shandite: $Co_3Sn_2S_2$, WALTER SCHNELLE, ANDREAS LEITHE-JASPER, HELGE ROSNER, MPI for Chemical Physics of Solids, Dresden, Germany, RICHARD WEIHRICH, Institute for Inorganic Chemisty, Universität Regensburg, Germany — The rapid advance in spintronics challenges an improved understanding of the underlying microscopic properties. Here, we present a joint experimental and theoretical study of $Co_3Sn_2S_2$ (shandite) and related compounds. From magnetic susceptibility, specific heat and magneto-transport measurements on a shandite single crystal sample we find a phase transition to a ferromagnetic metallic state at 177 K with a saturation moment of 0.92 μ_B/f.u. Full potential electronic structure calculations within the local spin density approximation result in a halfmetallic ferromagnetic groundstate with a moment of 1 μ_B/f.u. and a tiny gap in the minority spin channel. The calculated structure optimization and structure variations show that the size of the gap is rather sensitive to the lattice geometry. Possiblities to stabilize the halfmetallic ferromagnetic behavior by various substitutions have been studied theoretically and will be discussed.

10:36AM A17.00012 Thermodynamic and anisotropic properties of single crystalline RCo_2Ge_2 (R = Y, La-Nd, Sm-Tm)[1] , TAI KONG, MALINDA BUFFON, XIAO LIN, ALEX THALER, Iowa State University, Ames Laboratory, CHARLES CUNNINGHAM, Ames Laboratory, SERGEY BUD'KO, PAUL CANFIELD, Iowa State University, Ames Laboratory — Single crystals of RCo_2Ge_2 (R = Y, La-Nd, Sm-Tm) were grown using a self-flux method and were characterized from 1.8-300 K by heat capacity, magnetization and in-plane resistivity measurements. Anisotropic metamagnetism was studied at 1.8 K up to 9 T. Due to a strong crystal electric field (CEF) effect, the magnetic ordering temperatures of the heavy rare earth members do not follow the de Gennes scaling, but rather a CEF modified trend. The RCo_2Ge_2 series offers an opportunity to study different types of magnetic anisotropy ranging from Heisenberg-like $GdCo_2Ge_2$ to Ising-like $TbCo_2Ge_2$. Correlation between the local moments and conduction electrons as well as the influence of interplay between CEF effect and long-range indirect exchange interaction (RKKY type) will also be discussed.

[1]This work is supported by the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

10:48AM A17.00013 Resistivity and anisotropic magnetization of single crystalline $R\mathrm{Ni}_{1-x}\mathrm{Bi}_{2\pm y}$ (R = La–Nd, Sm, Gd–Dy)[1] , X. LIN, Iowa State University, WARREN STRASZHEIM, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory, US DOE, Iowa State University — We present a detailed study of $R\mathrm{Ni}_{1-x}\mathrm{Bi}_{2\pm y}$ (R = La–Nd, Sm, Gd–Dy) single crystals by measurements of temperature dependent magnetic susceptibility, magnetization, and electrical resistivity. The isostructural compounds $RT\mathrm{Bi}_2$ and $RT\mathrm{Sb}_2$ are known to have widths of formation, except for T = Ag. The $R\mathrm{Ni}_{1-x}\mathrm{Bi}_{2\pm y}$ series forms with partial Ni occupancy as well as a variable Bi occupancy. For R = Ce–Nd, Gd–Dy, the $R\mathrm{Ni}_{1-x}\mathrm{Bi}_{2\pm y}$ compounds show local-moment-like behavior and order antiferromagnetically at low temperatures. Determination of anisotropies as well as antiferromagnetic ordering temperatures for $R\mathrm{Ni}_{1-x}\mathrm{Bi}_{2\pm y}$ (R = Ce–Nd, Sm, Gd–Dy) have been made. Although crystalline samples from this family exhibit minority, second phase, superconductivity at low temperatures associated with Ni-Bi and Bi contamination, no evidence of bulk superconductivity has been observed.

[1]This work was supported by AFOSR-MURI grant FA9550-09-1-0603 (X. Lin and P. C. Canfield) and by US DOE under the Contract No. DE-AC02-07CH11358 (W. E. Straszheim and S. L. Bud'ko).

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A18 DMP FIAP GMAG: Focus Session: Spin-transfer Torque: Devices and Dynamics

320 - Dan Ralph, Cornell University

8:00AM A18.00001 Spin transfer torque in ferroelectric tunnel junctions , ARTHUR USEINOV, King Abdullah University of Science and Technology (KAUST), Physical Science and Engineering Division, Thuwal 23955-6900, Saudi Arabia., AURELIEN MANCHON, King Abdullah University of Science and Technology (KAUST), Physical Science and Engineering Division, Thuwal 23955-6900, Saudi Arabia — The worldwide interest for spintronics grows up every year, magnetic oscillators and resistance switchers became an important part of electronics with promising applications such as tunable microwave radiation, magnetic memory cells, magnetic field sensors, etc. A non-equilibrium spin-dependent transport in magnetic tunnel junctions comprising a ferroelectric barrier was studied. The exact solutions of the free electron Schrödinger equation for electron tunneling in the presence of interfacial screening are obtained by Bessel and Airy functions. As a result, bias-dependence of the tunneling magneto- and electro-resistance are obtained. The barrier asymmetry induced by the ferroelectric polarization produces strong modifications compared to regular tunnel junctions in the bias-dependence of the transport properties. Furthermore, manipulating the electric polarity of the barrier provides a way to control the magnitude and sign of the spin transfer torque.

8:12AM A18.00002 Spin-transfer torque at finite bias from density functional theory and non-equilibrium Green's functions[1]

, STEFANO SANVITO, MARIA STAMENOVA, IGOR POPOV, IVAN RUNGGER, Trinity College Dublin — The spin-transfer torque (STT) exerted on a magnetic layer by a spin-polarized current represents a powerful handle to manipulate the magnetization. This can make magnetic random access memories a reality. We have now implemented STTs in the electron transport code Smeagol (www.smeagol.tcd.ie), which combines density functional theory with the non-equilibrium transport formalism. In particular we are able to compute the STT both in the linear response limit and at finite bias, and for magnets with an arbitrary complex electronic structure, including spin-orbit interaction. Examples will be provided for both magnetic tunnel junctions and spin-polarized scanning tunnel microscopy of magnetic ions on non-magnetic surfaces.

[1]This work is suported by CRANN

8:24AM A18.00003 Current-Induced Spin Wave Instability

, SCOTT BENDER, YAROSLAV TSERKOVNYAK, UCLA, ARNE BRATAAS, NTNU — Current in conducting ferromagnets imparts angular momentum to the magnetic texture. Above a critical current, an instability is reached wherein this angular momentum transfer is able to overcome intrinsic damping, and spin waves begin to grow exponentially in time. We examine the conditions required to observe this instability for bulk and surface spin waves in different dimensions, and investigate the subsequent spin wave turbulence engendered by nonlinear terms in the Hamiltonian that couple different modes.

8:36AM A18.00004 Magnetic droplets in nano-contact spin-torque oscillators with perpendicular magnetic anisotropy[1]

, JOHAN ÅKERMAN, University of Gothenburg — The theoretical prediction, by Ivanov and Kosevich [1], of "magnon drop" solitons in thin films with perpendicular magnetic anisotropy (PMA) and zero damping, dates back to the 1970s. More recently, Hoefer, Silva and Keller [2], demonstrated analytically and numerically that related "magnetic droplet" solitons should be possible to excite in nano-contact spin-torque oscillators (NC-STOs) based on PMA materials, where spin transfer torque locally realizes the zero-damping condition required in [1]. In my talk, I will present the first experimental demonstration of such magnetic droplets, realized using 50-100 nm diameter nano-contacts (NCs) fabricated on top of orthogonal GMR stacks of Co8/Cu/Co0.3[Ni0.8/Co0.4]x4 (thicknesses in nm). The nucleation of a magnetic droplet manifests itself as a dramatic 10 GHz drop in microwave signal frequency at a drive-current dependent critical perpendicular field of the order of 0.5 - 1 T. The drop in frequency is accompanied by a simultaneous sharp resistance increase of the device and a sign change of its magnetoresistance, directly indicating the existence of a reversed magnetization in a region of the [Co/Ni] free layer underneath the NC. As predicted by numerical simulations the droplet exhibits rich magnetodynamic properties, experimentally observed as auto-modulation at approximately 1 GHz and sometimes sidebands at 1/2 and 3/2 of the fundamental droplet frequency. The 1 GHz modulation can be shown numerically to be related to the drift instability of the droplet [2], albeit with enough restoring force to make the droplet perform a periodic motion instead of leaving the NC region. The sidebands at 1/2 and 3/2 the droplet frequency are related to eigenmodes of the droplet perimeter. Magnetic droplet nucleation is found to be robust and reproducible over a wide number of NC-STOs with different NC sizes, making this new nanomagnetic object as fundamental and potentially useful to nanomagnetism as e.g. domain walls and vortices.

9:12AM A18.00005 Precessional magnetization reversal in magnetic tunnel junctions with a perpendicular polarizer[1]

, HUANLONG LIU, New York University — The interaction between the spins of itinerant electrons and the magnetization of ferromagnetic materials is of great interest both for fundamental physics and applications. While a ferromagnetic layer can polarize the spin of electrons passing through it, a spin-polarized current also changes the magnetization of the ferromagnet via a spin-transfer torque (STT). Here we present an orthogonal spin transfer device [1] with an in-plane magnetized free layer (FL) and a perpendicularly magnetized spin polarizing layer, separated by a thin copper spacer. The initial STT acting on the in-plane FL is perpendicular to the plane due to the spin polarization from the polarizer. For large torques, the FL magnetization will be tilted out of its easy plane, which creates a demagnetization field on the order of tens to hundreds of millitesla. The FL magnetization will then precess about the demagnetization field. The FL in our device forms a magnetic tunnel junction with an in-plane magnetized reference layer (RL), which is used to read out the state of the free layer. The resistance of the device then depends on the relative orientation between the magnetizations of the FL and the RL. We experimentally demonstrated fast switching of the FL magnetization, switching for pulses less than 500 ps in duration [2]. We also conducted subthreshold single-shot time-resolved resistance measurements that probe the FL magnetization reversal mechanisms on time scales in which thermal fluctuations can play an important role. We identify the antiparallel (AP) and parallel (P) states and the transition between these two states during a pulse from single-shot oscilloscope traces. We find that there is a strong asymmetry between the AP to P and P to AP transitions under the same pulse conditions [3]. The different switching processes can be explained by the strength of the perpendicular spin torque, which depends on the pulse current through the device and is initially larger in the P state than in the AP state. Spin torques from the RL also influence both the switching process and the switching probability. Our results illustrate new ways to control the magnetization of a nanomagnet on short time scales and optimize device operation.

9:48AM A18.00006 Energy landscape for switching in spin-valve nanopillars with perpendicular magnetic anisotropy[1]

, DANIEL B. GOPMAN, Physics Department of New York University, DANIEL BEDAU, JORDAN KATINE, San Jose Research Center, Hitachi-GST, ERIC E. FULLERTON, CMRR, University of California, San Diego, STEPHANE MANGIN, Institut Jean Lamour, UMR CNRS 7198, Nancy Universite, A.D. KENT, Physics Department of New York University — Recent experiments have established that thermally activated switching in perpendicularly magnetized spin-valve (SV) nanopillars larger than about 40 nm in diameter is dominated by sub-volume nucleation and domain wall propagation. Despite this complex behavior, room temperature measurements of the switching field distributions indicate thermal activation over a single energy barrier [1]. To better understand the magnetization reversal process, we conducted temperature dependent studies of the switching statistics in nanopillars in which we stabilize non-uniform magnetization states formed by a sub-volume nucleation event. We present results on Co—Ni free layers in SV nanopillars, which include a perpendicularly magnetized fixed layer. Here we measure the distribution of switching events as a function of temperature from 20 K to 300 K. The temperature dependence of both nucleation and propagation distributions is consistent with a thermal activation model, with distinct field-dependent barrier heights for each stage in the reversal process. This is evidence of an energy landscape for switching, which should be relevant for understanding the switching of SV devices even at temperatures that no longer show metastable non-uniform states. 10:00AM A18.00007 Thermally-assisted magnetization reversal in nanomagnets with spin-transfer torque: diffusive energy space dynamics[1] , DANIELE PINNA, A.D. KENT, Department of Physics, New York University, New York, NY 10003, D.L. STEIN, Department of Physics, New York University, New York, NY 10003 and Courant Institute of Mathematical Sciences, New York University, New York, NY 10012 — A direct current applied to a nanomagnet produces a spin-transfer torque that drives the magnetization out of equilibrium.[2] In this talk, scalings between switching time and current for a macrospin under the effects of both spin-torque and thermal noise are explored analytically by focusing on its diffusive energy space dynamics. The procedure allows us to characterize the full dynamics with a one dimensional stochastic differential equation.[3] We establish the limits of this reduction and elucidate the nature of the limit cycle stabilities observed in nanomagnet reversal experiments. We further proceed to show that the thermally activated dynamics in the presence of a tilt between easy and spin-polarization axes differ only by a rescaling of the threshold current as long as easy, hard and spin-polarization axes all lie in the same plane. Our analytics are verified by employing modern GPU computational techniques to massively parallelize the Langevin equations and probing the long time switching behavior.

10:12AM A18.00008 Electron tunneling induced nonequilibrium magnetization noise in single Co nanoparticles[1] , WENCHAO JIANG, FELIPE TIJIWA BIRK[2], DRAGOMIR DAVIDOVIC, School of Physics, Georgia Institute of Technology — We have studied magnetic hysteresis loops of single Co nanoparticles in Al/Al_2O_3/(Co nanoparticles)/Al_2O_3/Al tunnel junctions using electron tunneling measurement at mK-temperatures. The magnetic switching field decreases and its distribution broadens versus tunneling current while the current does not heat the environment. The finding indicates that the magnetic switching field can be interpreted as a thermometer of the nonequilibrium magnetization noise. We present a phenomenological model that incorporates magnetic anisotropy fluctuations among discrete levels, to explain the noise properties.

10:24AM A18.00009 X-ray imaging of magnetic normal modes driven by spin transfer torque in magnetic nanopillar devices , LIN XUE, YONG-TAO CUI, R.A. BUHRMAN, D.C. RALPH, Cornell University, TOLEK TYLISZCZAK, Advanced Light Source, LBNL, MI-YOUNG IM, PETER FISCHER, Center for X-ray Optics, LBNL — We have used time-resolved x-ray microscopy to image the fundamental dynamical modes that are driven by spin transfer torque in magnetic devices. We apply a continuous microwave current to exert an oscillating spin torque in a nanopillar structure. By varying frequency and the applied magnetic field, this spin torque selectively excites different individual magnetic normal modes, which are then imaged by x-ray pulses synchronized to the microwave current. We obtain images with 70 ps time resolution and 25 nm spatial resolution. Our results identify modes having different spatial distributions of amplitude and phase, which can be explained by the combined effects of spin transfer torque and the Oersted field. We will discuss the implications of our results for understanding spin-torque-driven magnetic dynamics.

10:36AM A18.00010 Spin Dynamics and Resonant Inelastic X-ray Scattering in Chromium with Commensurate Spin-Density Wave Order , KOUDAI SUGIMOTO, ZHI LI, Yukawa Institute for Theoretical Physics, Kyoto University, EIJI KANESHITA, Sendai National College of Technology, KENJI TSUTSUI, Condensed Matter Science Division, Japan Atomic Energy Agency, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University — After the discovery of iron-pnictide superconductors, the spin dynamics of itinerant antiferromagnetic systems with multi-orbital has attracted much attention. In order to elucidate such spin dynamics, we focus on a similar system, chromium, which is known to show a spin density wave (SDW), and theoretically investigate dynamical spin susceptibilities and L_3-edge resonant inelastic X-ray scattering (RIXS) spectra [1]. We use multi-band Hubbard model composed of $3d$ and $4s$ orbitals. After the SDW mean-field approximation, we obtain the dynamical spin susceptibilities and RIXS spectra by employing random phase approximation. In our calculation, we assume the perfect commensurate SDW state. We find a collective spin-wave excitation undamped up to ~ 0.6 eV. Above the energy, excitation overlaps individual particle-hole excitations as expected. In RIXS spectra, particle-hole excitations with various orbital channels show a large spectral weight, masking the spectra of the spin collective mode. However, it may be possible to detect the spin-wave excitation in RIXS experiments in the future if resolution is high enough. [1] K. Sugimoto, Z. Li, E. Kaneshita, K. Tsutsui, and T. Tohyama, arXiv:1211.1598

10:48AM A18.00011 Spin Transfer torques in Antiferromagnets , HAMED SAIDAOUI, KAUST University, XAVIER WAINTAL, SPSMS, CEA, Grenoble, France, AURELIEN MANCHON, KAUST University, SPSMS, CEA, GRENOBLE FRANCE COLLABORATION — Spin Transfer Torque (STT) has attracted tremendously growing interest in the past two decades. Consisting on the transfer of spin angular momentum of a spin polarized current to local magnetic moments, the STT gives rise to a complex dynamics of the magnetization. Depending on the the structure, the STT shows a dominated In plane component for spin valves [1], whereas both components coexist for magnetic tunneling junctions (MTJ) [2]. For latter case the symmetry of the structure is considered to be decisive in identifying the nature and behavior of the torque [3]. In the present study we are interested in magnetic structures where we substitute either one or both of the magnetic layers by antiferromagnets (AF). We use Non-equilibrium Green's function formalism applied on a tight-binding model to investigate the nature of the spin torque. We notice the presence of two types of torque exerted on (AF), a torque which tends to rotate the order parameter and another one that competes with the exchange interaction. We conclude by comparison with previous works [4-5].

8:00AM A19.00001 Microscopic Evidence for Slater-Type Metal-Insulator Transition in Sr_2IrO_4[1]

MINGHU PAN, QING LI, Oak Ridge National Laboratory, G.-X. CAO, University of Tennessee, Knoxville, SATOSHI OKAMOTO, G. ZHENG, WENZHI LIN, BRIAN C. SALES, Oak Ridge National Laboratory, J.Y. YI, J.-Q. YAN, University of Tennessee, Knoxville, R. ARITA, University of Tokyo, J. KUNES, Institute of Physics, Czech Republic, M. IMADA, University of Tokyo, D. MANDRUS, University of Tennessee, Knoxville — The interplay between spin-orbit coupling, bandwidth and on-site coulomb repulsion in layered 5d transition metal oxides (TMO) acquired much interest recently. In Sr_2IrO_4, the interplay opens a gap near the Fermi energy and stabilizes a $J_{\rm eff}$ =1/2 spin-orbital entangled insulating state at low temperatures. However, whether this metal-insulating transition (MIT) is Mott-type (electronic-correlation driven) or slater-type (magnetic order driven) is still under hot debate. In this presentation, we give, for the first time, the atomic resolved structure of Sr_2IrO_4 surface in real space by using scanning tunneling microscopy. Tunneling spectroscopic results illustrate the gap opening of Sr_2IrO_4 at low temperatures with the gap size of 250 mV, indicating the metal to insulator transition. More importantly, the pair of peaks around gap in spectra suggests the quasi-particle coherent excitation, implying the Slater-type insulating state. This is further confirmed by temperature dependent measurements and density functional theory calculations.

8:12AM A19.00002 Magnetotransport properties of Sr_2IrO_4 thin films modulated by epitaxial strain

LUDI MIAO, DAE HO KIM, ZHIQIANG MAO, Tulane University — Sr_2IrO_4 (SIO) has attracted much attention due to its $J_{\rm eff}$ =1/2 Mott state induced by relativistic spin-orbit coupling [1]. In $3d/4d$ transition metal oxides, exotic phenomena, such as high-$T_{\rm C}$ superconductivity and colossal magnetoresistance, occur when a Mott insulting state is suppressed by charge carrier doping or band width tuning. Whether the Mott state in SIO can be tuned to new exotic states is an interesting question under active investigation. We have grown epitaxial SIO films on the substrates of $SrTiO_3$(STO) and $NdGaO_3$ (NGO) using a pulsed laser deposition method and investigated the strain effect on the properties of SIO. The SIO/STO film exhibits a tetragonal structure, while the SIO/NGO film displays a orthorhombic structure due to the NGO's orthorhombic nature. Although both types of films show insulating properties, their magnetic properties appear to be distinct: the SIO/STO film shows negative magnetoresistance (MR) with negligible anisotropy, whereas the SIO/NGO film exhibits positive MR with two-fold anisotropy. Such differences in magnetotransport imply the strong coupling between the lattice, spin and orbital degrees of freedom in SIO.

8:24AM A19.00003 Magneto-transport of filling controlled Mott insulator, Sr_2IrO_4

JAYAKANTH RAVICHANDRAN, DMITRI EFETOV, Department of Physics, Columbia University, New York, NY 10027, CLAUDY RAYAN SERRAO, DI YI, RAMAMOORTHY RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, CA 94720, PHILIP KIM, Department of Physics, Columbia University, New York, NY 10027 — Sr_2IrO_4 (SIO) is shown to be a special Mott insulator with the ground state stabilized by a combination of electron correlation and spin-orbit coupling. [1] Both structurally and electronically, electron doped SIO shows characteristics comparable to hole doped La_2CuO_4, one of the parent compounds of the high-T_c cuprates. [2] This leads us to a natural question of whether doped SIO can turn into a metal and eventually a superconductor. Sustained efforts of chemically doping SIO, [3] without altering its band structure significantly, have been severely hampered due to solubility limitations. In this work, we perform a combination of chemical and electrostatic doping of SIO, to explore the possibility of achieving a robust metallic state. We show that undoped SIO shows ambipolar characteristics and there is significant gating action even after heavy alloying of SIO with La. In depth magneto-transport measurements such as Hall effect and magnetoresistance also provide us a deeper understanding of electronic structure and transport in this exotic Mott insulator.

8:36AM A19.00004 Visualizing the gap closure by Rh dopant in SOC induced Mott insulator Sr_2IrO_4 with Scanning Tunneling Microscopy

JIXIA DAI, EDUARDO CALLEJA, KYLE MCELROY, Department of Physics, University of Colorado at Boulder, TONGFEI QI, GANG CAO, Center for Advanced Materials and Department of Physics and Astronomy, University of Kentucky — Sr_2IrO_4 is a novel $J_{\rm eff}$ =1/2 Mott insulator with characteristics of 5d electrons. The strong spin orbit coupling (SOC) in the 5d orbitals of iridium plays an important role in the insulating nature of the parent compound, while replacing Ir^{4+} with the isoelectronic Rh^{4+} is able to drive the system to a metallic regime. We use variable temperature Scanning Tunneling Microscope to study both the insulating parent compound and the Rh doped $Sr_2Ir_{1-x}Rh_xO_4$, with x=0.04, 0.11. By doing differential conductance measurement, we were able to observe an insulating gap both in the parent compound and the low doping areas of the x=0.04 and 0.11 samples. We also observed that in the doped samples, local gaps varies largely at the atomic length scale. By correlating the locations of Rh dopant and the size of local gaps, we found that Rh doping will decrease the insulating gap size which is in accordance with the metallic behavior observed by transport measurements.

8:48AM A19.00005 Heterostructuring iridate-based spin-orbit Mott materials

JIAN LIU, DI YI, CLAUDY R. SERRAO, JIUN-HAW CHU, S. SURESHA, ASHVIN VISHWANATH, UC Berkeley, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, XAVI MARTI, RAMAMOORTHY RAMESH, UC Berkeley — Mott materials with strong spin-orbital coupling (SOC) have emerged as a new playground for searching quantum many-body phases with exotic electronic and magnetic properties. Numerous attentions have been paid to 5d transition metal oxides due to the intriguing opportunities to obtaining novel topological insulators, superconductivity, Weyl semimetals, quantum spin liquid, and so on. While realizing these fascinating phenomena would lead to a new generation of electronic and spintronic devices, the rich physics derived from the cooperation of strong correlation and SOC remains to be explored. Here we present our investigation on using epitaxy to control perovskite-based strontium iridates, a prototype of 5d complex oxides, as ultrathin films and heterostructures. We utilize epitaxial stabilization, strain, confinement and interfacial coupling to tune the competing interactions and the multiple degrees of freedom. The combination of these various controls offers a unique pathway to novel phase behaviors and innovative functions. Our experimental findings derived from transport, magnetometry and advanced resonant x-ray spectroscopy, including linear and circular dichroism, will be discussed.

9:00AM A19.00006 Probing spatial evolution of local density of states in Sr3Ir2O7

YOSHINORI OKADA, DANIEL WALKUP, WENWEN ZHOU, Boston College, TAY-RONG CHANG, National Tsing Hua University, HSIN LIN, Northeastern University, SOVIT KHADKA, CHETAN DHITAL, Boston College, HORNG-TAY JENG, National Tsing Hua University, ARUN BANSIL, Northeastern University, ZIQIANG WANG, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — Amongst the iridate families, the Ruddlesden-Popper series ($Sr_{n+1}Ir_nO_{3n+1}$) goes through a transition from insulator to metal with increasing n. Within this series the n =2 compound $Sr_3Ir_2O_7$ (Ir327) occupies a unique place, straddling a well-defined insulator (n =1) on one side and a metal (n =infinity) on the other, placing Ir327 in close proximity to a delicate and interesting transition point. In this study, we probe the spatial evolution of the local density of states (LDOS) of Ir327 by means of scanning tunneling spectroscopy. In the parent Ir327 compound, we find local regions of metallic density of states that exist within an underlying insulating electronic structure. Based on the experimental data, we discuss the mechanism of how this metallic LDOS evolves from the intrinsically gapped electronic structure in terms of spin-orbit and Coulomb interactions.

9:12AM A19.00007 Strongly spin-orbit coupled spin-3/2 model for $5d^1$ AB_2O_4 spinels[1] , YI-PING HUANG, GANG CHEN, MICHAEL HERMELE, University of Colorado Boulder — Research on 5d transition metal oxides has been more and more active recently. Unlike in 3d transition metals, the strong spin orbit interaction cannot be treated as a perturbation. The competition between correlation, spin orbit coupling and the kinetic energy of 5d electrons makes the problem nontrivial. We model the AB_2O_4 spinel structure with single d electron on atom B as a Hubbard type model. By treating the hopping term perturbatively under large spin orbit coupling we derive an effective spin 3/2 model which is not Heisenberg-like. We further investigate the possible phase diagram of the effective spin 3/2 model.

[1]This work is supported by DOE award no. DE-SC0003910.

9:24AM A19.00008 Unusual magnetic phases in the strong interaction limit of two-dimensional topological band insulators in transition metal oxides[1] , MEHDI KARGARIAN, The University of Texas at Austin, ABDOLLAH LANGARI, Sharif University of Technology, GREGORY A. FIETE, The University of Texas at Austin — The expected phenomenology of non-interacting topological band insulators (TBI) is now largely theoretically understood. However, the fate of TBIs in the presence of interactions remains an active area of research with novel, interaction-driven topological states possible, as well as new exotic magnetic states. In this work we study the magnetic phases of an exchange Hamiltonian arising in the strong interaction limit of a Hubbard model on the honeycomb lattice whose non-interacting limit is a two-dimensional TBI recently proposed for the layered heavy transition metal oxide compound, $(Li,Na)_2IrO_3$. By a combination of analytical methods and exact diagonalization studies on finite size clusters, we map out the magnetic phase diagram of the model. We find that strong spin-orbit coupling can lead to a phase transition from an antiferromagnetic Neél state to a spiral or stripy ordered state. We also discuss the conditions under which a quantum spin liquid may appear in our model, and we compare our results with the different but related Kitaev-Heisenberg-J_2-J_3 model which has recently been studied in a similar context.

9:36AM A19.00009 Time-reversal symmetry breaking and anomalous Hall effect in heavy fermion metals , WENXIN DING, QIMIAO SI, Department of Physics and Astronomy, Rice University — Motivated by recent experimental evidence for a possible chiral spin liquid phase in the metallic pyrochlore heavy fermion iridates (Pr_2 Ir_2 O_7) [Phys.Rev.Lett, **96**, 087204 (2006), Phys.Rev.Lett **98**, 057203 (2007), Nature **463**, 210 (2010), Phys.Rev.Lett, **106**, 217204 (2011)], we study the effect of Kondo coupling on a time-reversal symmetry breaking state of the $J_1 - J_2$ model on square lattices. We use a slave fermion representation for the f-moments which are coupled to conduction electrons, and study the mean field solution in the large-N limit. We calculate the ground state energies of various feasible states, and map out the mean field phase diagram by energetic consideration. As the probe for time-reversal symmetry breaking, we calculate the anomalous Hall response for the chiral phase. Finally we discuss the implications of our results on the pyrochlore heavy-fermion iridates.

9:48AM A19.00010 The low-energy magnetic excitations of a three-band Hubbard model with a strong spin-orbit coupling for 5d transition metal oxide Sr_2IrO_4 , TOMONORI SHIRAKAWA, HIROSHI WATANABE, SEIJI YUNOKI, Computational Condensed Matter Physics Laboratory, RIKEN ASI — $5d$ transition metal oxides in a layered perovskite structure such as Sr_2IrO_4 have attracted much attention because of their unique properties caused by a strong relativistic spin-orbit coupling of $5d$ transition element. Recent experiments on Sr_2IrO_4 have revealed that the low-energy magnetic excitations can be described by an "isospin"-1/2 Heisenberg model with an effective exchange interaction as large as $\sim$ 60-100 meV. Motivated by these experiments, we study theoretically the ground state magnetic structure and the low-energy magnetic excitations for Sr_2IrO_4 using a three-band Hubbard model with the spin-orbit coupling. Our results demonstrate that the low-energy magnetic excitations are well described by an effective antiferromagnetic Heisenberg model composed of a local Kramers doublet. The estimated value of the effective exchange interaction is as large as 79 meV, which is in good quantitative agreement with the experiments.

10:00AM A19.00011 First-order metal-insulator transitions in vanadates from first principles , ANIL KUMAR, KARIN RABE, Dept of Physics and Astronomy, Rutgers University — Materials that exhibit first-order metal-insulator transitions, with the accompanying abrupt change in the conductivity, have potential applications as switches in future electronic devices. Identification of materials and exploration of the atomic-scale mechanisms for switching between the two electronic states is a focus of current research. In this work, we search for first-order metal-insulator transitions in transition metal compounds, with a particular focus on d^1 and d^2 systems, by using first principles calculations to screen for an alternative low-energy state having not only a electronic character opposite to that of the ground state, but a distinct structure and/or magnetic ordering which would permit switching by an applied field or stress. We will present the results of our investigation of the perovskite compounds $SrVO_3$, $LaVO_3$, $CaVO_3$, YVO_3, $LaTiO_3$ and related layered phase, including superlattices and Ruddlesden-Popper phases. While the pure compounds do not satisfy the search criteria, the layered phases show promising results.

10:12AM A19.00012 Real-time dynamics in electron-lattice coupled system: Numerical study on an extended double-exchange model , WATARU KOSHIBAE, CMRG, RIKEN, NOBUO FURUKAWA, Aoyama-Gakuin Univ., NAOTO NAGAOSA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG, CERG, RIKEN — We have developed a new theoretical method to study the photo-induced insulator-to-metal (IM) transition in strongly correlated electron systems [PRL **103**, 266402 ('09); EPL **94**, 27003 ('11).]. In the manganese oxides, it has been observed that the photo-induced dynamics with several tens of THz in frequency can drive IM transition [Nature Materials **6**, 643 ('07).]. The excitation energy with several tens of THz in frequency is fairly lower than the insulating energy gap of the electronic state. In this study, we introduce an extended double exchange model where the conduction electron couples with the orbital-ordering field and lattice distortion, and numerically examine the lattice vibration induced IM transition in the electron-lattice coupled system. To simplify the numerical calculation, the electronic states are restricted in the Hilbert space for perfect ferromagnetic states involving the ground state. In the numerical simulation, we find that the low frequency vibration of Jahn-Teller distortion can change the orbital-ordering pattern and trigger the IM transition. A threshold behavior of the lattice-vibration induced IM transition and the electron-hole excitation by continuous forced lattice-vibration are also examined.

10:24AM A19.00013 Photo-doped carrier dynamics in Mott insulatoring systems , EIKI IYODA, SUMIO ISHIHARA, Department of Physics, Tohoku Univ., JST-CREST — Electron/hole doping in Mott insulators, for example two-dimensional cuprates, has been well investigated in relation to high-Tc superconductivity. Especially related to photo-doping, many experiments on photo-induced phase transition in strongly correlated systems have been made. In the usual photo-doping setup, the system is excited with fs-laser pulse and generated electron-hole pairs affect properties of materials. Recently, another type of photo-doped experiment with heterostructure has been made, and hole or electron carriers are dynamically injected through the heterostructure. In this theoretical study, we examine photo-doped carrier dynamics in the t-J model with dynamically doped holes. We formulate dynamics of the carriers by non-equilibrium Green functions. We take an initial state of holes and decompose the non-equilibrium Green's function into a series of equilibrium Green's functions by using Wick's theorem. The effect of the initial distribution appears from the higher terms in the series. We treat magnons with the self-consistent Born approximation. The non-equilibrium Green function derived in this way shows double time dependence. We will present physical quantities in transient process, for example, one-particle excitation spectra for holes.

10:36AM A19.00014 Tailoring spin-orbit Mott insulators via designed superlattices , VIJAY SHANKAR V, Department of Physics, University of Toronto, Toronto, Canada, JOBU MATSUNO, RIKEN Advanced Science Institute, Wako, Japan, TOMOHIRO TAKAYAMA, Department of Advanced Materials, University of Tokyo, Japan, M. AHZAN ZEB, Cavendish Laboratory, University of Cambridge, Cambridge, UK, HAE-YOUNG KEE, Department of Physics, University of Toronto and Canadian Institute for Advanced Research, Toronto, Canada, HIDENORI TAKAGI, Department of Physics, University of Tokyo, and RIKEN Advanced Science Institute, Japan — The layered perovskite iridates $Sr_{n+1}Ir_nO_{3n+1}$ show a transition from a magnetic insulating to a semi-metallic state as the number of layers n is increased. This behaviour is intimately related to the interplay between spin-orbit coupling, electronic correlations and dimensionality. In this talk, we will show that the fabricated superlattices [($SrIrO_3$)/$SrTiO_3$], provide new insight into this behaviour. Theoretical calculations using density functional and tight binding approaches will be presented to support our results.

10:48AM A19.00015 Tuning the conductivity of $LaMnO_3/SrTiO_3$ superlattices by stacking[1] , YANPENG YAO, KARIN RABE, Rutgers, the State University of New Jersey, DEPARTMENT OF PHYSICS AND ASTRONOMY TEAM — First-principles density-functional-theory calculations have been applied to study the structure and electronic properties of ultrathin $LaMnO_3/SrTiO_3$ superlattices. We predict that upon the change of stacking, antiferromagnetic $LaMnO_3/SrTiO_3$ superlattices can be tuned from non-conducting insulator to conducting metal. The corresponding microscopic structure change in the superlattices is also analyzed. We find that the metal-insulator transition is accompanied by a corresponding reduction/disappearance of the Jahn-Teller (JT) distortion in the $LaMnO_3$ layer. The findings of this work illustrate the role of the JT distortion in the conductivity of transition-metal perovskites, and also suggest a new method for tuning metal-insulator transitions for functional device design.

Session A20 DMP: Focus Session: Metamaterials 322 - John Pendry, Imperial College London

8:00AM A20.00001 Symmetry Breaking and Optical Negative Index of Closed Nanorings , BOUBACAR KANTE, YONG-SHIK PARK, KEVIN O'BRIEN, DANIEL SHULDMAN, NORBERTO DANIEL LANZILLOTTI-KIMURA, ZI JING WONG, XIAOBO YIN, XIANG ZHANG, NSF Nanoscale Science and Engineering Centre, 3112 Etcheverry Hall, University of California, Berkeley, UC BERKELEY TEAM — We report the first experimental demonstration of broadband negative-index metamaterial made solely of closed metallic nanorings. Using symmetry breaking that negatively couples the discrete nanorings, we measured negative phase delay in our composite chess metamaterial. Our approach open avenues towards topological nanophotonics with on demand linear and non-linear responses.

8:12AM A20.00002 A subwavelength magnetic metamolecule , FARBOD SHAFIEI, FRANCESCO MONTICONE, KHAI LE, XING-XIANG LIU, THOMAS HARTSFIELD, ANDREA ALU, XIAOQIN LI, University of Texas-Austin — The weakness of magnetism at optical frequencies in nature has led to intense effort to create artificial magnetism, which is at the basis of anomalous refractive properties and other exciting optical phenomena. Plasmonic nanoclusters have been shown to exhibit strong magnetic response because magnetic effects are indistinguishable from spatial dispersion of permittivity at optical frequencies. In a different context, plasmonic Fano resonances have raised great interest, particularly for use in sensing applications that benefit from sharp spectral features and extreme field localization. So far, optical Fano resonances have been based on purely electric effects. In this work, we use an atomic force microscope to assemble a four-particle nanoring consisting of Au nanoparticles of approximately 100 nm in diameter and to actively modify its configuration until we observed the desired spectral response in the total scattering cross section, namely the first magnetic-based optical Fano resonance in a subwavelength metamolecule. Support from ARO, AFOSR, NSF, and ONR are gratefully acknowledged.

8:24AM A20.00003 Bridging the Gap Towards the Monolithically Integrated Selective Polarizer: A Dynamic Metamaterial Polarization Grid , COREY SHEMELYA, NICOLE PFIESTER, Tufts University, GANESH BALAKRISHNAN, University of New Mexico, THOMAS VANDERVELDE, Tufts University — The use of active metamaterials in devices has gained much attention recently based on their scalabilty, tunability, and the ability to turn them on or off. This work describes the use of metamaterial patterning to create a dynamic polarizer for monolithic integration on photodetectors. The design was tuned for wavelengths in the mid-infrared transmission window for the use of sensing man-made objects. Samples were fabricated using Si doped GaAs epitaxially grown on a c-plane sapphire substrate. Gold metamaterials were patterned and deposited along with ohmic and schottky contacts using physical vapor deposition. The results are compared to similar metamaterials on various substrate materials: double-sided polished (DSP) intrinsic GaAs, DSP n-type GaAs, N+ GaSb, and p-type Si.

8:36AM A20.00004 Geometry Induced Optimization of Energy Consumption in an Ultrafast Metamaterial Modulator , ATISH AGARWALA, Swarthmore College, Swarthmore, PA and Femtosecond Spectroscopy Unit, Okinawa Institute of Science and Technology, Okinawa, Japan, KESHAV DANI, Femtosecond Spectroscopy Unit, Okinawa Institute of Science and Technology, Okinawa, Japan — We investigate the energy consumption per bit of an all-optical ultrafast metmaterial modulator via improvements in the geometric design of the device. The device is a 100nm thick tri-layered Ag-Si-Ag fishnet structure metamaterial with a negative index resonance in the NIR. Previously, the device has been shown to be capable of terabit per second all-optical modulation requiring 3nJ/bit of energy. In this talk, we study different device geometries including stacked fishnet structures and variations in sidewall angles in order to reduce the energy consumption required to switch a single bit. Our simulations indicate an optimized structure that allows us to reduce our energy requirement to only 25pJ/bit for a device integrated with an optical fiber. Such improvements in energy consumption are essential for future practical devices allowing for terabit per second all-optical communication. They also provide insight into future energy-efficient metamaterial photonic devices.

8:48AM A20.00005 Impact of patterned anti-reflection coating on the performance of Broadband Blackbody Absorber Based on Dielectric-Thin Metal Film Multilayers , SHYHAUH GUO[1], Department of Materials Science and Engineering, University of Maryland, College Park, MD, ANDREI SUSHKOV, DENNIS DREW[2], Department of Physics, University of Maryland, College Park, MD, RAYMOND PHANEUF[3], Department of Materials Science and Engineering, University of Maryland, College Park, MD — We present results from measurements on double period structures of alternating dielectric and thin metal layer coated with micro-patterned anti-reflection layer to improve absorption in mid-infrared range. We examine the effect on performance of patterns' period and the correlation with the effective medium theory. We find that the numerical results agree with the measured absorption spectra. We also investigate the limit of pattern feature size to achieve performance suggested by effective medium theory.

9:00AM A20.00006 Solving the inverse problem of metamaterials with permittivity measurement , HON PING LEE, KA SHING HUI, KIN WAH YU, The Chinese University of Hong Kong — We have developed a new strategy for the reconstruction of volume fraction distribution of metallic inclusion in a graded composite from the measured electric permittivity data. Some of the techniques by Milton[1] and McPhedran[2] on homogenous two phase composites, together with Bergman-Milton representation, electromagnetic representation of effective permittivity and optimization method are used, and the strategy consist of the following two parts: reconstructing the effective permittivity in spectral space with Bergman representation by minimizing the cost function, and obtaining the volume fraction distribution by a contact of Bergman representation and electromagnetic representation of effective permittivity. Demonstration of the strategy is carried out by typical monotonically decreasing graded profile. The study could be extended to arbitrary profiles. The results obtained are useful for solving various inverse problems for the reconstruction of the structures of composites.

9:12AM A20.00007 Theory of Spatial Optical Solitons in Metallic Nanowire Materials , MARIO SILVEIRINHA, Instituto de Telecomunicacoes - University of Coimbra — Arrays of metallic nanowires stand as one of the most exciting structures in the metamaterial realm due to their applications in the electromagnetic field manipulation and transport in the nanoscale. Nanowire materials can also lead to interesting physics in the context nonlinear optics, and in particular previous works have shown that stable subwavelength solitons can be formed in arrays of metallic nanowires embedded in a Kerr-type material. Such solitary waves can have an important impact in nanophotonics and in the realization of ultra-compact devices. Thus, it would be highly interesting to characterize them using an effective medium approach, because this can highlight the relevant physical processes and simplify the numerical modeling. In this talk, we derive an effective medium theory that describes the dynamics of the macroscopic electromagnetic fields in a nanowire array embedded in a Kerr-type dielectric. We apply such a theory to the characterization of optical solitons, and unravel the physical mechanisms that enable the formation of stable subwavelength solitary waves in nanowire arrays. It is shown that because of the exotic hyperbolic dispersion of the photonic states in a nanowire material, the effective medium behaves as a self-focusing material when the nanowires are embedded in a self-defocusing dielectric host.

9:48AM A20.00008 Development of Metamaterial Structures by Laser Direct-Write[1] , ALBERTO PIQUE, NICHOLAS CHARIPAR, HEUNGSOO KIM, MATTHEW KIRLEIS, Naval Research Laboratory, ANDREW SMITH, Nova Research Inc. — The use of metamaterials structures has been the subject of extensive discussions given their wide range of applications. However, a large fraction of the work available to date has been limited to simulations and proof-of-principle demonstrations. One reason for the limited success inserting these structures into functioning systems and real-world applications is the high level of complexity involved in their fabrication. Direct-write processes are ideally suited for the fabrication of arbitrary periodic and aperiodic structures found in most metamaterial and plasmonic designs. For these applications, laser-based processes offer numerous advantages since they can be applied to virtually any surface over a wide range of scales. Furthermore, laser direct-write or LDW allows the precise deposition and/or removal of material thus enabling the fabrication of novel metamaterial designs. This presentation will show examples of metamaterial and plasmonic structures developed at the Naval Research Lab using LDW, and discuss the benefits of laser processing for these applications.

10:00AM A20.00009 Design of Tunable Superconducting Metamaterials[1] , MELISSA TREPANIER, DAIMENG ZHANG, STEVEN ANLAGE, University of Maryland — Our goal is to create a superconducting metamaterial utilizing deep sub-wavelength meta-atoms with a quickly-tunable index of refraction. To accomplish this we will combine two different materials: an array of rf SQUIDs (with tunable effective permeability) and an array of thin wires interrupted by Josephson junctions (with tunable effective permittivity). These materials have been designed to maximize tunablility in the range easily measured via X-band, Ku-band, and K-band waveguides. Various sizes of rf SQUIDs were designed to be non-hysteretic, be sufficiently insensitive to noise, and to have resonant frequencies ranging from 6.5 - 22 GHz. The wire array was designed so that the inductance of the Josephson junctions can completely cancel the geometric and kinetic inductance of the wires, giving rise to strong tunability. We will present the design considerations and simulation results for this new class of metamaterials.

[1]This work is supported by the NSF-GOALI program through grant # ECCS-1158644, and CNAM.

10:12AM A20.00010 Measurement of a SQUID metamaterial[1] , DAIMENG ZHANG, MELISSA TREPANIER, STEVEN ANLAGE, University of Maryland, College Park — We report experimental results on a new type of superconducting metamaterial consisting of arrays of RF SQUIDs operating in the microwave frequency range with tunable properties (S parameters, effective permeability, effective permittivity, etc.). DC magnetic field is applied to bias the sample and to vary the Josephson inductance, thus tuning the resonant frequency over a multi-GHz range. The experiment is done in a magnetic-shielded cryostat where we examine the temperature, RF-field, and DC-field dependence of S parameters of this superconducting metamaterial. We also perform a cryogenic calibration to eliminate the effects of transmission lines on our results. From the calibrated S-matrix of this metamaterial, we are able to extract the effective permeability and its response to various stimuli.

10:24AM A20.00011 Experimental demonstration of a broadband array of invisibility cloaks in the visible frequency range[1] , VERA SMOLYANINOVA, Towson University, IGOR SMOLYANINOV, University of Maryland, KURT ERMER, Towson University — Since the first experimental demonstration in the microwave and visible ranges, invisibility cloaks stimulated considerable progress in the fields of metamaterials and transformation optics. Arrays of invisibility cloaks may find important applications in low-interference communication, noninvasive probing, sensing and communication networks, etc. We report on the first experimental realization of such an array of broadband invisibility cloaks, which operates in the visible frequency range. Wavelength and angular dependencies of the cloak array performance will be demonstrated. Potential biochemical sensing applications will be discussed.

[1]This work is supported by NSF grants DMR-0348939 and DMR-110476.

10:36AM A20.00012 Experimental demonstration of birefrigent broadband transformation Luneburg lenses[1] , HENRY ERMER, VERA SMOLYANINOVA, ALEX PIAZZA, TODD ADAMS, DAVID SCHAEFER, Towson University, IGOR SMOLYANINOV, University of Maryland — Transformation optics (TO) has recently become a useful methodology in the design of unusual optical devices, such as novel metamaterial lenses and invisibility cloaks. Here we report the first experimental realization of birefrigent TO designs of Luneburg lens based on lithographically defined metal/dielectric waveguides. Adiabatic variations of the waveguide shape enable control of the effective refractive indices experienced by the TE and TM modes propagating inside the waveguides. We have studied wavelength and polarization dependent performance of the resulting birefrigent TO devices. These novel optical devices considerably extend our ability to control light on submicrometer scales.

[1]This work is supported by NSF grants DMR-0348939 and DMR-110476.

10:48AM A20.00013 Electromagnetic "black holes" in hyperbolic metamaterials , IGOR SMOLYANINOV, University of Maryland — We demonstrate that spatial variations of the dielectric tensor components in a hyperbolic metamaterial may lead to formation of electromagnetic "black holes" inside this metamaterial. Similar to real black holes, horizon area of the electromagnetic "black holes" is quantized in units of the effective "Planck scale" squared. Potential experimental realizations of such electromagnetic "black holes" will be considered. For example, this situation may be realized in a hyperbolic metamaterial in which the dielectric component exhibits critical opalescence.

Session A21 DMP: Focus Session: New Ferroelectrics and Ferroelectric Mechanisms 323 - Eric Bousquet, Universite de Liege

8:00AM A21.00001 Effects of Manganese Addition on Ferroelectric Properties of $BaTiO_3$: Ab initio Study , IVAN NAUMOV, R.E. COHEN, Carnegie Institution of Washington — As it is well known, Mn is intensively used to improve the electromechanical properties of perovskite oxides like $BaTiO_3$, $PbTiO_3$ or $PbZr_xT_{1-x}O_3$. Despite the interest in Mn as a dopant, it is currently poorly understood from the fundamental point of view. Here, we present the results of our ab initio study aimed to elucidate the role of Mn defects and associated with them vacancies on the electronic, atomic and ferroelectric properties of $BaTiO_3$. Namely, we discuss the equilibrium geometry and electronic properties of the Mn ions occupying A or B sites and their valence or oxidation states in the presence or absence of an compensated oxygen vacancy. A special attention is given to the formation of dipole moments $\mathbf{P}_{\mathrm{d}}$ associated with the dopants and to the interaction between $\mathbf{P}_{\mathrm{d}}$ and spontaneous polarization $\mathbf{P}_{\mathrm{s}}$. This work is supported by the US Office of Naval Research.

8:12AM A21.00002 Understanding the role of A-site and B-site cations on piezoelectric instability in lead–free (1-x) $BaTiO_3$ – $xA(Cu_{1/3}Nb_{2/3})O_3$ (A = Sr, Ca, Ba) solid solutions[1] , DEEPAM MAURYA, YUAN ZHOU, SHASHANK PRIYA, Center for Energy Harvesting Materials and Systems (CEHMS), Bio-Inspired Materials and Devices Laboratory (BMDL), Virginia Tech, Blacksburg, VA 24061 — This study provides fundamental understanding of the enhanced piezoelectric instability in lead-free piezoelectric (1-x) $BaTiO_3$-$xA(Cu_{1/3}Nb_{2/3})O_3$(A: Sr, Ba and Ca and x = 0.0-0.03) solid solutions. These compositions were found to exhibit large longitudinal piezoelectric constant (d_{33}) of ∼330 pC/N and electromechanical planar coupling constant (*kp*) ∼ 46% at room temperature. The X-ray diffraction coupled with atomic pair distribution functions (*PDF*)s indicated increase in local polarization. Raman scattering and electron paramagnetic resonance (EPR) analysis revealed that substitutions on A and B-site both substantially perturbed the local octahedral dynamics and resulted in localized nano polar regions with lower symmetry. The presence of nano domains and local structural distortions smears the Curie peak resulting in diffuse order-disorder type phase transitions. The effect of these distortions on the variations in physical property was modeled and analyzed within the context of nanodomains and phase transitions. *spriya@vt.edu

8:24AM A21.00003 First-principles-based modeling of epitaxial-strain-induced ferroelectricity in $CaTiO_3$, QIBIN ZHOU, KARIN RABE, Rutgers University — Epitaxial strain can be used to induce phase transitions from the bulk phase to non-bulk phases in thin films and superlattices. In $CaTiO_3$, it has been previously shown that tensile epitaxial strain induces a transition from the nonpolar bulk orthorhombic phase to a ferroelectric phase. In this study, our first-principles computations revealed that compressive strain also induces ferroelectric phases, one of which has unexpected in-plane polarization. To construct a parametrized energy function that reproduces the properties of $CaTiO_3$ for epitaxial strain over a wide range, I developed an approach in which the parameters in a symmetry expansion are determined by a combination of curve-fitting and constraints to computed first-principles results. This energy function allows the analysis of the competition between the oxygen-octahedron-rotation distortion and the polar mode. The use of this function in modeling the structures and properties of superlattices containing $CaTiO_3$, and in constructing effective Hamiltonian for large scale studies, will be discussed.

8:36AM A21.00004 Proper, improper and hybrid improper ferroelectricity in oxide perovkites and related compounds , PHILIPPE GHOSEZ, University of Liège — Ferroelectricity in oxide perovskites and related compounds has been a topic of intensive research for more than 60 years. Recently, the coupling of the ferroelectric mode with other structural distortions has attracted an increasing interest since it offers promising and still widely unexplored possibilities to couple ferroelectricity with other functional properties and even to produce unusual phenomena. In this context, the trilinear coupling between ferroelectric and oxygen rotational modes in naturally occuring and artificial layered perovskites appeared as a practical way to produce unusual dielectric properties or achieve enhanced magneto-electric coupling. Here, I will first briefly reintroduce the concepts of proper, improper and hybrid improper ferroelectricity, highlighting how to rationalize better the concept of improper ferroelectricity. I will contrast the intrinsic behavior of these three classes of compounds in ferroelectric capacitors. Taking then the prototypical example of BiFeO3/LaFeO3 superlattices, I will illustrate how hybrid improper ferroelectricity and trilinear mode coupling is a promising route to potentially achieve electric switching of the magnetization. Finally, considering the case of PbTiO3/SrTiO3 superlattices, I will discuss how to access from first-principles the phase-transition sequence and finite temperature properties of complex systems combining various structural instabilities, which still remains a challenging issue.

9:12AM A21.00005 Nanoscale design routes to polar oxides , JOSHUA YOUNG, JAMES RONDINELLI, Drexel University — Many useful material properties, such as ferroelectricity, arise because of inversion symmetry breaking in a material's ground state. Understanding how to purposefully lift spacial parity operations is critical to engineering compounds with 'acentric' properties. Using first-principles density functional calculations, we describe the crystal-chemistry criteria necessary to design artificial nanoscale oxides that display spontaneous polarizations using non-polar metal-oxygen polyhedra. By controlling the flavor of A-site cation ordering in $AA'B_2O_6$ perovskites, we show that spontaneous electric polarizations comparable in magnitude to conventional ferroelectrics are attainable. We conclude by explaining how the criteria can be extended to other material classes to realize polar oxides by design.

9:24AM A21.00006 Turning ABO_3 antiferroelectrics into ferroelectrics: Design rules for practical rotation-driven ferroelectricity in double perovskites and Ruddlesden-Popper compounds , ANDREW T. MULDER, School of Applied and Engineering Physics, Cornell University, NICOLE A. BENEDEK, Materials Science and Engineering Program, The University of Texas at Austin, JAMES M. RONDINELLI, Department of Materials Science and Engineering, Drexel University, CRAIG J. FENNIE, School of Applied & Engineering Physics, Cornell University — The discovery of octahedral rotation-induced ferroelectricity has provided a new avenue to realize novel materials to explore the interplay of the electrical polarization and correlated phenomena such as magnetism. Design rules recently established suggest ferroelectricity will exist in layered $AA'B_2O_6$ perovskites when at least one of the ABO_3 constituents forms in the nonpolar Pnma structure. As the majority of perovskites form in Pnma, these rules are widely accessible to many chemistries and therefore have the potential to lead to new classes of multifunctional materials. This recent advance however does not directly address the question of whether or not this polar state is a functional ferroelectric or simply a pyroelectric. In this talk we derive from first principles a chemically and physically intuitive model, based only on the properties of the ABO_3 constituents, to guide the realization of both large polarizations and small ferroelectric switching barriers. We show how this model follows from a complex interplay of octahedral rotations, antiferroelectric lattice distortions inherent in every Pnma material, and A-site cation ordering. Finally we demonstrate its applicability not only to the double perovskites but also to Ruddlesden-Popper compounds.

9:36AM A21.00007 First-principles calculations of epitaxially strained $PbZrO_3$: Coexistence of antiferroelectricity and ferroelectricity , SEBASTIAN E. REYES-LILLO, KARIN M. RABE, Department of Physics and Astronomy, Rutgers University — The antiferroelectric (AFE) - ferroelectric (FE) field-induced transition has important applications in energy-storage capacitors and piezoelectric devices. $PbZrO_3$ is the best known AFE material. Polycrystalline and single crystals $PbZrO_3$ posses a stable AFE ground state below 505 K. In thin films, experimental results show coexistence of antiferroelectricity and ferroelectricity at room and low temperatures. First-principles calculations of epitaxially strained $PbZrO_3$ are carried out to give further evidence of this coexistence and to study the polarization switching path. The space groups of the AFE and FE structures are identified together with their important structural and electrical features.

9:48AM A21.00008 New classes of piezoelectrics, ferroelectrics, and antiferroelectrics by first-principles high-throughput materials design , JOSEPH BENNETT, Rutgers University — Functional materials, such as piezoelectrics, ferroelectrics, and antiferroelectrics, exhibit large changes with applied fields and stresses. This behavior enables their incorporation into a wide variety of devices in technological fields such as energy conversion/storage and information processing/storage. Discovery of functional materials with improved performance or even new types of responses is thus not only a scientific challenge, but can have major impacts on society. In this talk I will review our efforts to uncover new families of functional materials using a combined crystallographic database/high-throughput first-principles approach. I will describe our work on the design and discovery of thousands of new functional materials, specifically the LiAlSi family as piezoelectrics, the LiGaGe family as ferroelectrics, and the MgSrSi family as antiferroelectrics.

10:24AM A21.00009 Prediction of ferroelectric order in $PbCrO_3$[1] , MARTIN SCHLIPF, MARJANA LEŽAIĆ, Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — In this contribution, we employ density-functional theory (DFT) to analyze the properties of $PbCrO_3$. Experimental observations indicate that $PbCrO_3$ exhibits a semiconducting ground state and crystallizes in a perfect cubic perovskite structure. However, symmetry considerations show that these two properties conflict with each other and as a consequence prior DFT calculations obtained a metallic ground state. Investigating tiltings and Jahn-Teller distortions of the oxygen octahedra with a DFT+U approach, we find a semiconducting ground state in which a polar shift of the ions is energetically favorable. Depending on the size of the Hubbard U parameter, we obtain either a structure with a $P4bm$ or one with a $P4_2mc$ space group. In the $P4bm$ structure, the mechanism driving the polar displacement is analogous to $PbVO_3$. The $P4_2mc$ structure is characterized by a displacive ferroelectic order caused by empty sp orbitals.

[1]Acknowledgement: Young Investigators Group Programme of the Helmholtz Association (Computational Nanoferronics Laboratory, Contract VH-NG-409)

10:36AM A21.00010 Why isn't $CsSnF_3$ ferroelectric? , EVA H. SMITH, School of Applied and Engineering Physics, Cornell University, NICOLE A. BENEDEK, Materials Science and Engineering Program, The University of Texas at Austin, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — Complex fluorides are an interesting class of materials to explore for new ferroelectrics and multiferroics. The elucidation of design rules for new ferroelectric fluorides is challenging because polar fluorides tend to form in structures with a large number of atoms in the unit cell and the ferroelectricity is almost always of the geometric type. In this talk we will discuss our recent attempt to rationally design new polar fluorides from first principles. By exploring the relative stability of the subgroups of the perovskite manifold (using the phonons of the 5-atom cubic structure as a guide), we reveal the origin of ferroelectricity in R3c $CsPbF_3$, the only known polar ABF_3 compound. Comparison with $CsSrF_3$, which has a similar tolerance factor but no lone pair cation, reveals that the interplay between lone-pair localization and rotations stabilizes the rotation pattern most compatible with ferroelectricity, *i.e.*, $a^-a^-a^-$, rather than the more common $a^-a^-c^+$. Next we replace Pb^{2+} with another lone pair cation, Sn^{2+}. Within a perovskite manifold of states $CsSnF_3$ is ferroelectric, yet synthesis of this compound by our experimental collaborators shows that not only isn't it ferroelectric, it isn't even a perovskite. Why?

10:48AM A21.00011 Why are there so few perovskite ferroelectrics? , NICOLE BENEDEK, The University of Texas at Austin, CRAIG FENNIE, Cornell University — Nearly all cubic ABO_3 perovskites are unstable to energy-lowering structural distortions, the most common being those that give rise to ferroelectricity (usually an off-centering of the B-site cation) and tilts or rotations of the BO_6 octahedra. Whereas there are many perovskites that are either ferroelectric or have rotated octahedra, there are very few perovskites that are both ferroelectric and have rotated octahedra. This observation has lead to the widespread assumption that rotations suppress ferroelectricity and vice versa. Using first-principles density functional theory calculations, in combination with crystal chemistry and symmetry principles, we show that rotations do not always suppress ferroelectricity. In fact, the most fertile place to search for new ferroelectrics may be the place that has thus far been considered the least likely to contain them: materials that are expected to have large rotations. We will show why and how ferroelectricity is suppressed in the most common space group adopted by perovskites (Pnma) and explain how we can use this knowledge to design new ferroelectrics and functional materials.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A22 DMP: Organic Conductors & Other Correlated Electron Systems 324 - Claude Bourbonnais, Universite de Sherbrooke

8:00AM A22.00001 Optical evidence of competitive nature between charge-order and dimer-Mott insulators , RYUJI OKAZAKI, YUKIO YASUI, ICHIRO TERASAKI, Department of Physics, Nagoya University, YUKA IKEMOTO, TARO MORIWAKI, SPring-8, JASRI, TAKAHISA SHIKAMA, HATSUMI MORI, ISSP, The University of Tokyo, KAZUYUKI TAKAHASHI, ISSP, The University of Tokyo and Department of Chemistry, Kobe University, HIDEKI NAKAYA, TAKAHIKO SASAKI, IMR, Tohoku University — A family of two-dimensional (2D) quarter-filled organic materials exhibits various intriguing electronic and magnetic states. These salts are essentially metallic due to the partially-filled band, however, several materials show the correlated insulating states such as charge-order and dimer-Mott insulators owing to strong correlation effects coupled with their unique internal degrees of freedom. In this talk, we show a competitive nature between charge-order and dimer-Mott insulating phases in the 2D quarter-filled organic salt β-(meso-DMBEDT-TTF)$_2$PF$_6$ through the optical conductivity measurements. This material has been known to exhibit charge ordering below $T_c = 70$ K. We find optical evidence of a dimer-Mott insulating phase above T_c, indicating that the transition in this material is a transition from dimer-Mott to charge-order insulator. Below T_c, the optical peak feature of dimer-Mott insulator is significantly suppressed by the formation of charge order, implying a competition of these two insulators in this system. Furthermore our infrared imaging spectroscopy reveals a spatially inhomogeneous electronic state far below T_c, which is attributed to the competition between charge-order and dimer-Mott insulators.

8:12AM A22.00002 Superconductivity and polar charge fluctuation in low dimensional organic salts , SUMIO ISHIHARA, AKIHIKO SEKINE, JOJI NASU, Department of Physics, Tohoku University — Organic conductors are one of the families in which exotic superconductivities have been examined intensively. Recently, dielectric anomaly is reported in one of the κ-type BEDT-TTF salts, κ-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$. A dielectric anomaly is observed in the temperature dependence of the dielectric constant around 30K. These experimental results trigger reinvestigations of the electronic structure in the dimer-Mott insulating systems, and a mechanism of the superconductivity. Superconductivity and polar charge fluctuation are studied in an organic conductor where the dimer-molecule degree of freedom exists. The two-types of the extended Hubbard models, where the intra- and inter-dimer Coulomb interactions are taken into account, are analyzed by the random-phase approximation and the fluctuation-exchange approximation. The superconductivity appears in a vicinity of the charge-density wave (CDW) phase where the electronic distributions are polarized inside dimers. The extended s-wave type paring is favored and is cooperative with the d$_{xy}$-type paring due to the spin fluctuation. This superconductivity is compared with that realized near the CDW phase where the charge is not polarized inside dimers.

8:24AM A22.00003 Collective charge excitation in low dimensional organic salts , MAKOTO NAKA, SUMIO ISHIHARA, Department of Physics, Tohoku University — Electronic ferroelectricity is known as phenomena where electric polarization is attributed to the charge order without inversion symmetry. This is seen in some transition metal oxides, e.g. LuFe$_2$O$_4$, and charge transfer salts. Quasi 2-dimesional organic salt kappa-(ET)$_2$Cu$_2$(CN)$_3$ is one of the electronic ferroelectricities. Two ET molecules construct a dimer and are arranged on a triangular lattice. Recently, it is reported that a dielectric anomaly is experimentally observed around 30K. An origin of this dielectric anomaly is thought to be an ?electronic? dipole generated by a localized hole in one side of the ET molecules in dimers. Motivated by the experimental results, we study charge dynamics in dimer-Mott insulating system with internal charge degree of freedom in a dimer. We adopt the three kinds of models, extended Hubbard model, V-t model and its effective pseudo-spin model. We analyze these models by utilizing the exact diagonalization method and spin wave approximation, and focus on the collective charge excitation. In the ground state, paraelectric dimer-Mott phase and ferroelectric charge ordered phase compete with each other. We find the low-energy intra-dimer charge excitations which show a strong light polarization dependence. The collective excitation mode which is observable by light being parallel to the electric polarization shows a softening and a remarkable frequency dispersion around the phase boundary. This collective charge excitation of the ?electronic? dipole explains the recently observed peak structure in optical conductivity for the THz region.

8:36AM A22.00004 Microscopic investigation of Fabre charge transfer salts as function of temperature and pressure , HELENE FELDNER, ANTHONY JACKO, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany, EVA ROSE, MARTIN DRESSEL, Physikalisches Institut, Universität Stuttgart, Pfaffenwaldring 57, D-70550 Stuttgart, Germany, ROSER VALENTI, HARALD O. JESCHKE, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — The Fabre charge transfer salts are quasi-1D materials with a rich temperature and pressure phase diagram. We use literature as well as newly obtained crystal structures to sample many temperatures and pressures (both chemical and physical). We find that general trends in their electronic properties can be connected to their phase diagram. Finally, we analyze the importance of correlations in these systems using an extended Hubbard model, parametrized using DFT Wannier orbital overlaps.

8:48AM A22.00005 LDA+DMFT investigation of the organic charge transfer salt κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Cl , JOHANNES FERBER, KATERYNA FOYEVTSOVA, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — We combine density functional theory with dynamical mean field theory for the study of organic molecular crystals using a new scheme to construct molecular Wannier functions. We calculate spectral and optical properties for the strongly correlated material κ-(BEDT-TTF)$_2$Cu[N(CN)$_2$]Cl. The new method allows us to analyze the contributions of intradimer and interdimer contributions to the optical conductivity on the same footing. We find in agreement with experiment that strong correlations lead to a Hubbard peak in the optical conductivity.

9:00AM A22.00006 Charge Induced Spin Polarization in Thiophene Oligomers , AVADH SAXENA, Los Alamos National Lab, DONG HOU, JUNJIE QIU, SHIJIE XIE, Shandong University — Charge induced spin polarization in organic small molecules is a key factor for spin transport and magnetic effects in related organic devices. We study the spin polarization in charged thiophene oligomer molecules by calculating the magnetic moment with density functional theory (DFT). We find that the emergence and variation of the net magnetic moment is related to both the amount of charge injected and the polymerization of the oligomer, i.e. the number of monomer units. Combined with model analysis, we conclude that the strong electron-electron (e-e) interaction and electron-lattice (e-l) interaction in organic materials are responsible for charge induced spin polarization in organic oligomers.

9:12AM A22.00007 Inter-chain transport in the quasi-one-dimensional metal, $Li_{0.9}Mo_6O_{17}$[1] , JOSHUA COHN, University of Miami, BENJAMIN D. WHITE, Montana State University, CARLOS A.M. DOS SANTOS, Escola de Engenharia de Lorena - USP, Brazil, JOHN J. NEUMEIER, Montana State University — We report measurements of electrical resistivity (ρ) and thermoelectric power (S) transverse to the conducting chains (crystallographic *c* axis) on single crystals of the quasi-one-dimensional metal, $Li_{0.9}Mo_6O_{17}$. While $\rho_c(T)$ exhibits metallic behavior at $T \leq T_{max} \sim 270$ K, it decreases with increasing T above this temperature similar to the behavior of ρ transverse to the conducting planes in a variety of two-dimensional metals.[2] We discuss the corresponding thermopower, S_c, which is relatively T-independent and a modest 30 μV/K at low T, increases sharply with increasing T near T_{max}, and exceeds 200 μV/K at $T > 400$ K.

9:24AM A22.00008 Nanoscale interplay of inhomogeneity and electron interactions in the quasi one-dimensional purple bronze $Li_{0.9}Mo_6O_{17}$[1] , JUNG HOON LIU, ANJAN SOUMYANARAYANAN, MICHAEL YEE, YANG HE, Harvard University, MARTHA GREENBLATT, Rutgers University, NIGEL HUSSEY, University of Bristol, JENNIFER HOFFMAN, Harvard University — The marked deviation from Fermi liquid behavior for the quasi one-dimensional (1D) purple bronze, $Li_{0.9}Mo_6O_{17}$ (LPB), has been observed by both bulk transport and surface sensitive spectroscopic probes, and has generated much theoretical interest. Here we report on spectroscopic scanning tunneling microscopy (STM) studies of 1D 'chains' on the surface of LPB in the presence of a magnetic field. While we can consistently identify high-energy features in the tunneling density of states corresponding to the bulk band structure, we find that the Coulomb suppression of tunneling around the Fermi energy is inhomogeneous on the nanometer length scale. We discuss the inhomogeneity in the context of the 1D 'chains', and its implications on other measurements.

9:36AM A22.00009 Direct observation of electronic nematicity in charge and orbital ordered $La_{0.33}Ca_{0.67}MnO_3$, J. TAO, Condensed Matter Physics & Materials Science Dept., Brookhaven National Laboratory, K. SUN, Dept of Physics, University of Michigan, J.M. ZUO, Department of Material Science and Engineering and F. Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Y. ZHU, Condensed Matter Physics & Materials Science Dept., Brookhaven National Laboratory — Nematic and smectic states have been demonstrated to be very important in understanding high-T_c superconductivity. Here we report similar observations of electronic nematicity in doped manganites. Both the electron diffraction results and HRTEM images obtained from single crystal domain of $La_{0.33}Ca_{0.67}MnO_3$ clearly show a C4 to C2 symmetry broken in charge ordered (CO) and orbital ordered superstructures at intermediate temperature range. The electronic nematicity persists in the crystal until long-range CO forms as a stripe phase at lower temperatures upon cooling. During warming process, we observed topological defects in the charge ordering superstructures, indicating that the melting of the CO superstructure is defect mediated. Theoretical simulations will also be provided for better interpretation of the phenomenon. Research at Brookhaven National Laboratory was sponsored by the US Department of Energy (DOE)/Basic Energy Sciences, Materials Sciences and Engineering Division under Contract DE-AC02-98CH10886.

9:48AM A22.00010 Checkerboard to Stripe Charge Ordering Transition in $TbBaFe_2O_5$, DANIEL PRATT, SUNG CHANG, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, WEI TIAN, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, ALEXEY TASKIN, YOICHI ANDO, Department of Frontier Materials Creation, Osaka University, Osaka Japan, JEREL ZARESTKY, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, ANDREAS KREYSSIG, ALAN GOLDMAN, ROBERT MCQUEENEY, Ames Laboratory, US DOE, Iowa State University, Ames, IA 50011, USA — A combined neutron and x-ray diffraction study of $TbBaFe_2O_5$ reveals a rare checkerboard to charge ordering transition. $TbBaFe_2O_5$ is a mixed valent compound where Fe^{2+}/Fe^{3+} ions are known to arrange into a stripe charge-ordered state below T_V = 291 K, that consists of alternating Fe^{2+}/Fe^{3+} stripes in the basal plane running along the **b** direction. Our measurements reveal that the stripe charge-ordering is preceded by a checkerboard charge-ordered phase between $T_V < T < T^* = 308$ K. The checkerboard ordering is stabilized by inter-site coulomb interactions which give way to a stripe state stabilized by orbital ordering.

10:00AM A22.00011 Novel electronic transition in layered $IrTe_2$, YOON SEOK OH, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, J.J. YANG, Laboratory for Pohang Emergent materials, Postech, Korea, Y. HORIBE, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University — Layered chalcogenides such as 1T-TaS_2, 1T-$TiSe_2$, Bi_2Se_3, and MoS_2 exhibit rich low-dimensional physical properties such as superconductivity, topological insulator, charge density waves (CDW), and field-effect-transistor with high mobility. $IrTe_2$ forms in the layered CdI_2 structure, and exhibits diamagnetism and superlattice modulations below $\sim$260 K. In addition, superconductivity appears when the $\sim$260 K transition is fully suppressed by, for example, chemical doping. The origin of the $\sim$260 K transition in $IrTe_2$ has been controversial. It was claimed to be a structural transition, which suppresses electronic conduction. It was also reported that Fermi surface instability drives the transition - *i.e.* it is charge density wave-type. In this talk, we present our comprehensive studies on electron diffraction and transport experiments under chemical/hydrostatic pressure to unveil the origin of the novel electronic transition in $IrTe_2$.

10:12AM A22.00012 Superstructure and its domain structure in layered $IrTe_2$ at low temperatures , Y. HORIBE, F.T. HUANG, Rutgers Center for Emergent Materials, and Department of Physics and Astronomy, Rutgers University, J.J. YANG, Laboratory for Pohang Emergent Materials, Postech, Korea, Y.S. OH, Y.J. CHOI, A. HOGAN, S.-W. CHEONG, Rutgers Center for Emergent Materials, and Department of Physics and Astronomy, Rutgers University — $IrTe_2$, forming in layered CdI_2 structure, exhibits a unique phase transition accompanied by the appearance of diamagnetism and a sharp increase of electrical resistivity. This transition has been discussed to be due to a charge-density-wave formation related to the Fermi surface nesting [1]. In this talk, we will report the three dimensional superstructure below the transition temperature, obtained from electron diffraction patterns using low-temperature transmission electron microscopy. The superstructure is characterized by the presence of the superlattice reflections with the modulation wave vector q= 1/5 [101]. Its domain structure and chemical doping effects on the modulation wave vector will also be discussed.

10:24AM A22.00013 Resonant Ultrasound Studies of Mo_3Sb_7[1] , LINDSAY VANBEBBER, Dept. of Materials Science and Engineering, University of Tennessee, JIAQIANG YAN, DAVID MANDRUS, Dept. of Materials Science and Engineering, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, BRIAN C. SALES, Materials Science and Technology Division, Oak Ridge National Laboratory, VEERLE KEPPENS, Dept. of Materials Science and Engineering, University of Tennessee — The elastic behavior of a series of $Mo_{3-x}M_xSb_{7-y}X_y$ (M= Cr, Ru, X= Te) single crystals is examined with resonant ultrasound spectroscopy (RUS) as a function of temperature (300 K - 5 K). The elastic response of the parent compound Mo_3Sb_7 reveals a transition at around 53K, evidenced by a dramatic softening in the shear modulus c=(c_{11}-c_{12})/2. This softening is associated with a cubic-to-tetragonal structural transition as well as a spin gap formation. The transition temperature is lowered by a few degrees upon doping with Cr. Doping with Ru and Te is known to suppress the structural transition, but the softening in the shear modulus suggests that a structural instability remains present in these compounds.

10:36AM A22.00014 Electronic thermoelectric power factor and metal-insulator transition in FeSb2[1] , CEDOMIR PETROVIC, QING JIE, RONGWEI HU, EMIL BOZIN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, ANNA LLOBET, Lujan Neutron Scattering Center, LANL, MS H805, Los Alamos, New Mexico 87545, USA, IGOR ZALIZNYAK, QIANG LI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — We show that synthesis-induced metal-insulator transition (MIT) for electronic transport along the orthorhombic c axis of FeSb2 single crystals has greatly enhanced electrical conductivity while keeping the thermopower at a relatively high level. By this means, the thermoelectric power factor is enhanced to a new do a new record high S2σ $\sim$8000 μWK$-$2 cm$-$1 at 28 K. We find that the large thermopower in FeSb2 can be rationalized within the correlated electron model with two bands having large quasiparaticle disparity, whereas MIT is induced by subtle structural differences. The results in this work testify that correlated electrons can produce extreme power factor values.

Session A23 DMP: Focus Session: Dopants and Defects in Semiconductors I 325 - Marek Skowronski, Carnagie Melon University

8:00AM A23.00001 Defects in Carbon-Based Materials , GERD DUSCHER, The University of Tennesse, Materials Science & Engineering — Two distinctly different carbon based semiconducting materials were investigated as to how point defects can influence the electric properties. SiC is a high power electronic material with high bulk mobility. The interface between SiC and SiO_2 is generally considered to be the cause for the reduced mobility of SiC devices compared to bulk SiC. We investigated this interface with atomic resolution Z-contrast and electron energy-loss spectroscopy. We come to the conclusion that the previously observed interface layer is due to the miscut and does not exhibit any stoichiometric change. The structure of the interface which is limiting the device performance is caused by the steps and facets at the interface introduced by the miscut. We observed a high number of carbon in the oxide right next to the interface. Aberration corrected transmission electron microscopy enabled the investigation of the atomic structure of this highly stepped interface and the impact of geometry and chemistry on the electronic properties of this material. Graphene is an emerging electronic material also with high mobility. We investigated the defects and dopants in graphene were investigated. We observed point and extended defects in this 2D material. Due to the clear observation of all atoms involved, this material can serve as a model material to study point defects directly. We observe a electronegativity doping of substitutional Si. We observed a remarkable resistance to oxidation of a variety of point defects of elements that readily oxidize in normal circumstances. Boron and nitrogen doped graphene was investigated and the exact nature of the dopant sites and interactions will be shown. Generally speaking modern electron microscopy can directly visualize the full atomic structures in geometrically simple materials like graphene. The knowledge of point defects can be the basis to understand the electronic property structure relationship of structurally complex materials like SiC.

8:36AM A23.00002 Characterization of the oxide-semiconductor transition layer in NO, P, and N-plasma passivated 4H-SiC/SiO_2 structures using transmission electron microscopy[1] , JOSHUA TAILLON, JOONHYUK YANG, University of Maryland, CLAUDE AHYI, JOHN WILLIAMS, Auburn University, JOHN ROZEN, LEONARD FELDMAN, Vanderbilt University, TSVETANKA ZHELEVA, AIVARS LELIS, US Army Research Laboratory, LOURDES SALAMANCA-RIBA, University of Maryland — The 4H-SiC/SiO_2 interface in MOSFET devices contains a high density of electrically active traps. Recent work has revealed an inverse relationship between the SiC-SiO_2 transition layer width and FET channel mobility. Interfacial N and P, introduced by nitric oxide (NO) anneals, nitrogen plasma (N2P), or phosphosilicate glass (PSG) passivations improve carrier mobility, but a relationship to transition layer width is lacking. We present a characterization of the SiC/SiO_2 transition layer as a function of NO anneal time using high resolution transmission electron microscopy (HRTEM), high-angle annular dark-field scanning TEM (HAADF-STEM), and electron energy-loss spectroscopy (EELS). The transition layer was measured with HRTEM and HAADF-STEM and characterized by the evolution of the C/Si and O/Si composition ratios and the Si-$L_{2,3}$ edge in the EEL spectra across the interface. We show an inverse relationship of NO anneal time and transition layer width, which correlates with improved channel mobility, increased N interfacial density, and reduced interface trap density. No excess C was noted at the interface. NO annealed samples are compared to N2P and PSG passivations.

8:48AM A23.00003 Study of surface potential variation in p-/n-type 4H-SiC using scanning kelvin probe microscopy , JUNG-JOON AHN, LIN YOU, Semiconductor and Dimensional Metrology Division, National Institute of Standards and Technology, Gaithersburg, MD, LIANGCHUN YU, GE Global Research, Niskayuna, NY, SANG-MO KOO, Kwangwoon University, Seoul, Korea, JOSEPH KOPANSKI, Semiconductor and Dimensional Metrology Division, National Institute of Standards and Technology, Gaithersburg, MD — We report surface potential images of p-n junctions in 4H-SiC measured using scanning kelvin probe microscopy (SKPM) and relate them to the local dopant concentration. SKPM has been demonstrated on various semiconductor materials to examine crystalline defects and doping profiles. SKPM measured surface potential depends on the local dopant concentration and clearly differentiates between n-type and p-type materials. As opposed to scanning capacitance microscopy, which requires a good quality surface insulating layer, SKPM requires a clean surface and the lack of a screening oxide might result in higher spatial resolution. For the measurement, partially de-processed SiC high power LMOSFETS were used. The p-n junctions were formed from 4H-SiC wafers having a p-epilayer on p-substrate that was ion-implanted with nitrogen and annealed to build a shallow n-type region. The samples were observed in plan-view and in cross-section. Amplitude modulated, double pass SKPM was implemented with a commercial AFM. We conducted a detailed study of various data acquisition parameters and it seems that the lateral resolution of the potential difference can be enhanced by applying higher ac modulation amplitude and small tip-sample scanning height.

9:00AM A23.00004 Near-infrared luminescent cubic silicon carbide nanocrystals for in vivo biomarker applications: an ab initio Study[1] , ADAM GALI, VIKTOR ZÓLYOMI, Wigner Research Center for Physics, Hungarian Academy of Sciences, BÁLINT SOMOGYI, Budapest University of Technology and Economics — Small molecule-sized fluorescent emitters are needed as probes to image and track the locations of targeted nano-sized objects with minimal perturbation, and are much sought-after to probe biomolecules in living cells. For in vivo biological imaging, fluorescent biomarkers have to meet the following stringent requirements: (i) they should be non-toxic and bioinert, (ii) their hydrodynamical size should be sufficiently small for clearance, (iii) they should be photo-stable. Furthermore, it is highly desirable that (iv) they have intense, stable emission in the near-infrared range, and (v) they can be produced in relatively large amount for biological studies. Here we report time-density functional calculations on SiC-based QDs in the aspect of in vivo biological imaging applications. We find that Si-vacancy, divacancy, as well as single metal dopants such as Vanadium (V), Molybdenum (Mo) and Tungsten (W) in molecule-sized (1-2 nm) SiC QDs emit light efficiently in the near-infrared range. Furthermore, their emission wavelength varies on the size of host SiC QDs at less extent than that of pristine SiC QDs, thus sharper emission spectrum is expected even in a disperse size distribution of these QDs. These fluorescent SiC QDs are paramagnetic in the ground state.

[1]EU FP7 DIAMANT (Grant No. 270197)

9:12AM A23.00005 The Search for Sub-Bandgap Optoelectronic Response in Silicon Hyperdoped with Gold , JONATHAN MAILOA, Massachusetts Institute of Technology, AUSTIN AKEY, Harvard School of Engineering and Applied Sciences, JAY MATHEWS, US Army Benét Laboratories, DAVID HUTCHINSON, Rensselaer Polytechnic Institute, CHRISTIE SIMMONS, JOSEPH SULLIVAN, MARK WINKLER, Massachusetts Institute of Technology, DAN RECHT, Harvard School of Engineering and Applied Sciences, PETER PERSANS, Rensselaer Polytechnic Institute, JEFFREY WARRENDER, US Army Benét Laboratories, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, TONIO BUONASSISI, Massachusetts Institute of Technology — Deep-level dopants have been long known as the lifetime-killer in microelectronic devices. Nevertheless, it has been shown that deep-level donor can facilitate strong absorption of light with energy below the semiconductor bandgap. Due to this strong sub-bandgap absorption, it is possible to engineer silicon devices exhibiting sub-bandgap optoelectronic response, such as silicon-based infrared photodetectors and intermediate-band solar cells. In this work, we show the optoelectronic response of silicon doped with a gold concentration surpassing the equilibrium solubility limit (gold-hyperdoped silicon, Au:Si). We fabricated Au:Si by ion implantation followed by nanosecond pulse laser melting, achieving a gold dopant concentration of over 10^{19} cm^{-3}. UV-VIS spectrophotometry was performed to measure sub-bandgap light absorption in the Au:Si layer. Our samples with the highest gold concentration have 10-15% absorption of sub-bandgap light. We will present and discuss the sub-bandgap optoelectronic response of this gold-doped silicon.

9:24AM A23.00006 Recombination lifetimes in laser hyperdoped Si layers measured via microwave photoconductive decay , JAY MATHEWS, US Army ARDEC - Benét Laboratories, DAVID HUTCHINSON, RYAN MCAVOY, Rensselaer Polytechnic Institute, MARK WINKLER, Massachusetts Institute of Technology, DANIEL RECHT, AUSTIN AKEY, Harvard University, JONATHAN MAILOA, Massachusetts Institute of Technology, MICHAEL AZIZ, Harvard University, TONIO BUONASSISI, Massachusetts Institute of Technology, PETER PERSANS, Rensselaer Polytechnic Institute, JEFFREY WARRENDER, US Army ARDEC - Benét Laboratories — Silicon hyperdoped with impurities via ion implantation followed by pulsed laser melting has attracted much attention lately due to potential for forming an intermediate band. Such materials have shown significant optical absorption well below the band gap of Si and are being explored for applications in photovoltaics and infrared detection. However, while optical absorption can be increased, high dopant concentration generally leads to a substantial decrease in recombination lifetime, which can detrimentally affect the performance of detectors and solar cells. In this work, we use microwave photoconductive decay (μ-PCD) to explore the transient behavior of Si hyperdoped with S at various levels. Excitation is achieved via a pulsed Nd:YAG laser at 355 nm (FWHM $\sim$ 5 ns), ensuring that carriers are generated only in the hyperdoped region. Decay times were found to decrease monotonically with increasing S concentration, and the highest concentrations do not show measureable photoconductivity, which could indicate unacceptably low lifetimes. Additional μ-PCD measurements are presented on Si hyperdoped with Au, which are promising despite the fact that Au is typically a "lifetime killer," as well as Si hyperdoped with Ti, which has been previously shown to exhibit lifetime recovery.

9:36AM A23.00007 Insulator-to-metal transition with deep-level impurities in silicon achieved by compensated hyperdoping , CHRISTIE SIMMONS, Massachusetts Institute of Technology, AUSTIN AKEY, Harvard School of Engineering and Applied Sciences, MARK WINKLER, IBM T.J. Watson Research Center, JACOB KRICH, University of Ottawa, JOSEPH SULLIVAN, Massachusetts Institute of Technology, DANIEL RECHT, OCI, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, TONIO BUONASSISI, Massachusetts Institute of Technology — Hyperdoping (achieved via nanosecond pulsed laser melting and rapid resolidification) allows the substitutional incorporation of impurities at concentrations orders of magnitude beyond the equilibrium solubility limit. This technique opens the door for studying the insulator-to-metal transition (IMT) in silicon doped with impurities for which the critical concentration necessary to drive the transition is inaccessible by conventional doping techniques; specifically, impurities that introduce deep, highly localized states. IMTs have already been observed for silicon hyperdoped with sulfur and with selenium. It may be possible to use these deep impurities to create an intermediate band semiconductor in which there is a delocalized band of impurity states isolated within the conventional band gap. We will discuss the possible nature of these IMTs (impurity band merging with the conduction band vs. closing of the Hubbard gap), and we will present further observations of a metal-to-insulator transition in highly compensated sulfur-doped samples. Sulfur is a double donor in silicon, and by adding varying concentrations of boron, a shallow acceptor, we demonstrate a tunable depletion of the impurity band as evidenced by the materials' optoelectronic properties.

9:48AM A23.00008 Optoelectronic Characterization of Impurity Supersaturated Silicon Junctions , DAVID HUTCHINSON, Rensselaer Polytechnic Institute, JOSEPH SULLIVAN, Massachussetts Institute of Technology, JAY MATHEWS, U.S. Army ARDEC-Benét Laboratories, DANIEL RECHT, AURORE J. SAID, Harvard University, DAVID J. LOMBARDO, Rensselaer Polytechnic Institute, CHRISTIE SIMMONS, TONIO BUONASSISI, Massachussetts Institute of Technology, JEFFREY M. WARRENDER, U.S. Army ARDEC-Benét Laboratories, MICHAEL J. AZIZ, Harvard University, PETER D. PERSANS, Rensselaer Polytechnic Institute — Intermediate band semiconductors have been proposed as a path to high efficiency photovoltaics. Silicon doped to high levels with impurities such as S, Se, Au, and Ti which can produce deep levels, may fulfill this promise. We report here on the optoelectronic properties of diode structures prepared by implantation of 10^{15} to 10^{16} impurity atoms/cm2 into a p-type or n-type wafers, followed by nanosecond pulsed laser melting and resolidification. Experimental results from wavelength and temperature dependent diode response, spatial quantum efficiency mapping, intensity dependent efficiency, and current-voltage characterization will be reported. Current-voltage measurements under photoexcitation yield information on the built in voltage and absorption mechanisms. Most devices show maximum quantum efficiency for excitation wavelengths between 900 and 1000 nm. The drop in quantum efficiency for short wavelengths can yield the minority carrier diffusion length in the hyperdoped material. Long wavelength response elucidates photocarrier excitation mechanisms. The fundamental properties of the junction and the supersaturated material will be discussed.

10:00AM A23.00009 Cross-spectrum noise spectroscopy for characterization of deep-levels in nanoscale devices , DEEPAK SHARMA, George Mason University, Fairfax, VA 22030, SERGIY KRYLYUK, MSED, National Institute of Standards and Technology, Gaithersburg, MD 20899, ABHISHEK MOTAYED, IREAP, University of Maryland, College Park, MD 20742, QILIANG LI, George Mason University, Fairfax, VA 22030, ALBERT DAVYDOV, MSED, National Institute of Standards and Technology, Gaithersburg, MD 20899 — Applications of traditional methods to study deep-levels, such as deep-level transient spectroscopy, or photo-induced current transient spectroscopy, often become impractical for nanoscale devices. In low frequency noise spectroscopy, the accurate measurements of the noise signal in low-current nanowire devices are extremely challenging because the device noise, which is proportional to the dc current, becomes comparable with the measurement setup noise. To overcome these issues, we have implemented a LFN measurement method based on dual-channel cross-spectrum analysis technique, which reduced the power spectral density (PSD) by three orders of magnitude by reducing the parasitic background 1/f noise, enabling high sensitivity measurements. The method was applied to probe deep-levels in n- and p-type Si nanowires grown by Ni and Au catalysts. Temperature-dependent noise measurement clearly showed Lorentzian peaks due to the generation-recombination (G-R) process via the deep levels introduced by Ni and Au atoms diffused into the Si nanowires during the growth. Important parameters such as trap energies and concentrations of the deep levels, minority carrier life times, hole and electron capture cross sections were calculated for both Ni and Au deep-levels.

10:12AM A23.00010 Defect engineering of complex semiconductor alloys: $Cu_{2-2x}M_xO_{1-y}X_y$[1] , STEPHAN LANY, National Renewable Energy Laboratory, VLADAN STEVANOVIC, Colorado School of Mines — The electrical properties of semiconductors are generally controlled via doping, i.e., the incorporation of dilute concentrations of aliovalent impurity atoms, whereas the band structure properties (gap, effective masses, optical properties) are manipulated by alloying, i.e., the incorporation of much larger amounts of isovalent elements. Theoretical approaches usually address either doping or alloying, but rarely both problems at the same time. By combining defect supercell calculations, GW quasi-particle energy calculation, and thermodynamic modeling, we study the range of electrical and band structure properties accessible by alloying aliovalent cations (M = Mg, Zn, Cd) and isovalent anions (X = S, Se) in Cu_2O. In order to extend dilute defect models to higher concentrations, we take into account the association/dissociation of defect pairs and complexes, as well as the composition dependence of the band gap and the band edge energies. Considering a composition window for the $Cu_{2-2x}M_xO_{1-y}X_y$ alloys of $0 \leq (x,y) \leq 0.2$, we predict a wide range of possible band gaps from 1.7 to 2.6 eV, and net doping concentrations between $p = 10^{19}$ cm^{-3} and $n = 10^{17}$cm^{-3}, notably achieving type conversion from p- to n-type at Zn or Cd compositions around x = 0.1.

[1]This work is supported as part of the SunShot initiative by the U. S. Department of Energy, Office of Energy Efficiency and Renewable Energy under Contract No. DE-AC36-08GO28308 to NREL.

10:24AM A23.00011 Ab-Initio Study of Defect Physics for Layered LaCuChO and BaCuChF (Ch={S,Se,Te}) Structures , JASON VIELMA, DAVID H. FOSTER, GUENTER SCHNEIDER, Oregon State University — Layered oxychalcogenides LnCuChO (Ln = {La,Pr,Nd}, Ch = {S,Se,Te}) and isostructural layered fluorochalcogenides BaCuChF have drawn much interest in recent years as p-type wide bandgap semiconductors with applications in transparent electronics and photovoltaics. Previous experimental and computational studies concluded for both LaCuChO, with a bandgaps between 2.4-3.1 eV, and BaCuChF, with optical bandgaps between 2.8-3.5 eV, that p-type conductivity is primarily due to copper vacancies. We report a comparative *ab-initio* computational study of the defect physics for both families of materials. Point defects and defect complexes are taken into account and previously omitted corrections have been included.[1,2] Accurate chemical potential stability diagrams and formation energies are calculated using the GGA+U method and fitted elemental-phase reference energies.[3]

10:36AM A23.00012 X-ray absorption spectroscopy to investigate the doping mechanism in amorphous Cu_2ZnSnS_4 thin films[1] , SIN CHENG SIAH, RUPAK CHAKRABORTY, Massachusetts Institute of Technology, PETER ERSLEV, GLENN TEETER, National Renewable Energy Laboratory, CHENJUN SUN, Argonne National Laboratory, TONIO BUONASSISI, Massachusetts Institute of Technology — Recently, Teeter *et al.* at NREL have discovered that Cu_2ZnSnS_4 thin films, of interest for photovoltaics, are amorphous (a-CZTS) when grown at room temperature and the film resistivity can be tuned over a wide range by controlling the Cu:Sn ratio. Tetrahedrally-coordinated amorphous semiconductors belong to an interesting class of compounds that are predicted to have the ability of being doped both p- and n-type. The four-fold coordination plays a critical role in unpinning the Fermi level to allow effective control over doping levels in a disordered structure. We performed extended X-ray absorption fine structure spectroscopy at the K-edges of Cu, Zn and Sn to determine the extent of structural disorder and tetrahedral coordination in a-CZTS films grown with varying Cu:Sn content. All films exhibit a high degree of structural disorder beyond the cations' first coordination shell. Both Cu and Zn atoms have high degree of tetrahedral coordination with respect to S atoms while the average coordination number of Sn decreases with increasing Sn content, indicative of either the favorable formation of sulfur vacancies around Sn atoms or the presence of Sn-related secondary phase. We combine these results with conductivity measurements to understand the relationship between the structural and electrical properties of this new material.

10:48AM A23.00013 Phonon-induced spin-spin interactions in diamond nanostructures: application to spin squeezing , STEVEN BENNETT, NORMAN YAO, JOHANNES OTTERBACH, Harvard University, PETER ZOLLER, University of Innsbruck, PETER RABL, TU Vienna, MIKHAIL LUKIN, Harvard University — We propose a novel mechanism for long-range spin-spin interactions in diamond nanostructures. The interactions are mediated by the coupling of electronic spins, associated with nitrogen vacancy centers, to the vibrational mode of a diamond mechanical nanoresonator. This results in phonon-mediated effective spin-spin interactions that can be used to generate squeezed states of a spin ensemble. We develop an approach combining spin echo techniques and coherent mechanical driving to suppress spin dephasing and relaxation, and find that substantial squeezing is possible under realistic experimental conditions. Our results have implications for spin-ensemble magnetometry, as well as phonon-mediated quantum information processing with spin qubits.

Session A24 DCOMP: Novel Technologies and Algorithms 326 - Brandon Cook, Oak Ridge National Laboratory

8:00AM A24.00001 Cubic-scaling algorithm and self-consistent mean field for the random-phase approximation with second-order screened exchange , JONATHAN MOUSSA, Sandia National Laboratories — The random-phase approximation including second-order screened exchange (RPA+SOSEX) is an accurate model of electron correlation energy with two caveats. Its accuracy depends on an arbitrary mean field choice and its scaling of $\mathcal{O}(n^5)$ operations and $\mathcal{O}(n^3)$ memory for n electrons cannot compete with the $\mathcal{O}(n^3)$ operations and $\mathcal{O}(n^2)$ memory scaling of density functional theory (DFT). We rederive RPA+SOSEX as an approximation of the Brueckner doubles coupled-cluster (BCCD) equations, which produces a self-consistent mean field and other model corrections. In addition, we present a new algorithm for RPA+SOSEX that matches the scaling of DFT. We verify the accuracy of the new model on H_2 dissociation and the uniform electron gas and verify the reduced scaling of the new algorithm on H_n rings.
This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

8:12AM A24.00002 Large-Scale Hybrid-DFT First-Principles Molecular Dynamics[1] , WILLIAM DAWSON, FRANCOIS GYGI, University of California Davis — The recursive subspace bisection algorithm[1] is used to accelerate the computation of the Hartree-Fock exchange operator in hybrid-DFT, First-Principles Molecular Dynamics (FPMD) simulations. This approach provides a set of maximally localized orbitals in domains of variable size and allows for a reduction of the number of computed exchange integrals with controlled accuracy. It does not require a priori assumptions about the localization of orbitals in limited domains and can be used with both occupied and empty orbitals, thus enabling computations of the HOMO-LUMO gap during hybrid-DFT FPMD simulations. We discuss algorithmic improvements of the method and demonstrate its use in hybrid-DFT FPMD simulations of water, solvated ions, and a liquid-solid interface in which maximally localized orbitals show a wide range of localization properties. 8:24AM A24.00003 One-shot calculation of the Electronic Structure across the Metal Insulator Transitions in V_2O_3 by Hybrid Density Functional , JOHN ROBERTSON, YUZHENG GUO, Cambridge University — We present the first calculation of the electronic structure of V_2O_3 in its different phases using the screened exchange (sX) hybrid functional [1]. The sX functional reproduces the observed band gaps, magnetic moments and photoemission spectra of the corundum paramagnetic metal (PM) phase, the monoclinic antiferromagnetic insulating (AFI) phase, and the corundum Cr-doped paramagnetic insulating (PI) phase. The PI phase has a 0.15eV band gap in good agreement with experiment. Using the generalised Kohn-Sham nature of the hybrid functional, a fully relaxed supercell model of the Cr-doped V_2O_3 PI phase is calculated, and it shows that the local strain field around Cr atoms is the driving force for the PI-PM transition. This illustrates that hybrid functionals that fix the exchange interaction can give a good, one-shot description of single particle spectra, and are efficient enough compared to DMFT or GW to treat the complex electron-lattice interactions that occur in the more interesting systems.

8:36AM A24.00004 Ab initio calculations of non-radiative carrier trapping due to deep impurity levels[1] , LIN-WANG WANG, Lawrence Berkeley National Laboratory, LIN SHI, Suzhou Institute of Nano-Tech and Nano-Bionics, CAS — Non-radiative carrier decay due to deep impurity levels in semiconductors is an important process which affects the efficiencies of devices from solar cells to light emitting diode. This process is due to multiple phonon emission. Despite of the fact the analytical formalisms have been derived long time ago, so far there is no direct ab initio calculations due to the high cost of calculating all the electron-phonon coupling constants. Here we introduce an algorithm which calculates all the electron-phonon coupling constants at once, hence allows the ab initio calculations of such processes. Another approximation is introduced to calculate the phonon modes of a given impurity system. We use a Zn_{Ga}-V_N paired defect in GaN as an example to study this process. We found that while most of the promoting phonon modes (used to promote the transition with the electron-phonon coupling) come from the optical modes, the accepting phonon modes (used to satisfy the energy conservation) come mostly from the acoustic phonons.

8:48AM A24.00005 Characterizing Oxidation State using Bader Analysis, Maximally Localized Wannier Functions and Atomic Orbitals Projection , KYLE REEVES, YOSUKE KANAI, University of North Carolina at Chapel Hill — The concept of oxidation state of atoms in molecules and materials is widely used to predict and understand chemical and physical properties. This concept is perhaps driven more empirically than by any rigorous criteria differentiating one oxidation state from another. Within the oxidation state framework, an integer number of electrons is assigned to the nuclei within a system. In practice, a distribution of electron density makes it difficult to quantify such discrete assignments without some ambiguities. We explore three different charge analysis approaches in density functional theory calculations for addressing the oxidation state of important organometallic molecules $[Ru(bpy)_3]^{2+}$ and $[Ru(bpy)_3]^{3+}$, which are widely used for solar energy conversion applications. Bader charge analysis, Wannier function analysis, and atomic orbital projection are employed in this work. Given the highly-localized nature of the d-electrons of the ruthenium atom, the charge analysis methods are also compared with Hubbard-U correction. We also discuss how the solvation by water molecules influences the oxidation state characterization for these organometallic complexes.

9:00AM A24.00006 Revised Basin Hopping Monte Carlo Algorithm Applied for Nanoparticles[1] , JUAREZ L. F. DA SILVA, Institute of Chemistry of Sao Carlos, USP, Brazil, GUSTAVO G. RONDINA, Institute of Physics of Sao Carlos, USP, Brazil — The Basin Hopping Monte Carlo (BHMC) algorithm has been very successful in obtaining the atomic structure of nanoparticles (NPs), however, its application for unbiased randomly initialized NPs have been restricted to few hundreds atoms employing empirical pair-potentials (EPP) and for small clusters employing first-principles interacting potentials based on density functional theory (DFT). In this talk, we will present our suggestions for bringing improvements to the the BHMC algorithm, which successfully extend its application for relatively large systems employing EPP and DFT potenticals. Using our implementation from scratch, we have found all the reported putative minimum energy configurations for Lennard-Jones and Sutton-Chen EPPs (N = 2 - 147, 200, 250, 300, ..., 1000). We addressed also binary systems described by the Lennard-Jones or Sutton-Chen empirical potentials, and excellent results have been obtained. Finally, our revised BHMC implementation was combined with DFT potentials (FHI-AIMS), which was employed to study the atomic structure of Al clusters from 2 - 55 atoms in the neutral and charged states. Thus, our results indicate the our suggestions provide an important contribution to improve the quality of the BHMC results employing EPP or DFT potentials.

9:12AM A24.00007 Generic parallel Wang-Landau sampling for complex systems , YING WAI LI, National Center for Computational Sciences, Oak Ridge National Laboratory, U.S.A., THOMAS VOGEL, DAVID P. LANDAU, Center for Simulational Physics, University of Georgia, U.S.A., THOMAS WÜST, Swiss Federal Research Institute WSL, Switzerland — We introduce a parallel realization for Wang-Landau sampling in Monte Carlo simulations based on a replica-exchange framework. The key idea is to split the entire energy range of the system under consideration into several smaller, overlapping sub intervals. The survey of configurational phase space can then be distributed over multiple processors, with exchanges of random walkers taking place in the overlapping energy windows. To demonstrate the robustness and advantages of this parallel scheme for the simulations of complex systems, we have applied it to protein adsorption problems using the HP lattice protein model[1]. The method gives significant speed-up and achieves strong scaling on small computer architectures like multi-core processors, with a possible improvement in accuracy. We believe that it could be potentially beneficial for large-scale petaflop machines.

9:24AM A24.00008 ABSTRACT WITHDRAWN –

9:36AM A24.00009 A Scientific Cloud Computing Platform for Condensed Matter Physics[1] , K. JORISSEN, W. JOHNSON, F. D. VILA, J. J. REHR, U. Washington — Scientific Cloud Computing (SCC) makes possible calculations with high performance computational tools, without the need to purchase or maintain sophisticated hardware and software. We have recently developed an interface dubbed SC2IT [1] that controls on-demand virtual Linux clusters within the Amazon EC2 cloud platform [2]. Using this interface we have developed a more advanced, user-friendly SCC Platform configured especially for condensed matter calculations. This platform contains a GUI, based on a new Java version of SC2IT, that permits calculations of various materials properties. The cloud platform includes Virtual Machines preconfigured for parallel calculations and several precompiled and optimized materials science codes for electronic structure and x-ray and electron spectroscopy. Consequently this SCC makes state-of-the-art condensed matter calculations easy to access for general users. Proof-of-principle performance benchmarks [1] show excellent parallelization and communication performance. [1] K. Jorissen, F.D. Vila, and J.J. Rehr, Comp. Phys. 9:48AM A24.00010 Anderson Localization: Dynamical Cluster Approximation - Typical Medium Theory Perspective[1] , CHINEDU EKUMA, ZIYANG MENG, Center for Computation & Technology and Department of Physics and Astronomy, Louisiana State University, HANNA TERLETSKA, Department of Physics and Astronomy, Louisiana State University, JUANA MORENO, MARK JARRELL, Center for Computation & Technology and Department of Physics and Astronomy, Louisiana State University, VLADIMIR DOBROSAVLJEVIC, Department of Physics, Florida State University — Mean field theories like the coherent potential approximation (CPA) and its cluster extensions, including the dynamical cluster approximation (DCA), fail to describe the Anderson localization transition in disordered systems. This failure is intrinsic to these theories as the algebraically averaged quantities used in them always favor the metallic state, and hence cannot describe the localization transition. Here we extend the Typical Medium Theory (TMT), which replaces the average quantities with their corresponding typical (geometrically averaged) equivalents, to its cluster form such that non-local correlations can be incorporated systematically. We apply our method to study the localization phenomena in various dimensions. Such an approach opens a new avenue to study localization effect both in model and in real materials.

10:00AM A24.00011 Gradient-Stable Linear Time Steps for Phase Field Models , BENJAMIN VOLLMAYR-LEE, Bucknell University — Phase field models, which are nonlinear partial-differential equations, are a widely used for modeling the dynamics and equilibrium properties of materials. Unfortunately, time marching the equations of motion by explicit methods is usually numerically unstable unless the size of the time step is kept below a lattice-dependent threshold. Consequently, the amount of numerical computation is determined by avoidance of the instability rather than by the natural time scale of the dynamics. This can be a severe overhead. In contrast, a gradient stable method ensures a decreasing free energy, consistent with the relaxational dynamics of the continuous time model. Eyre's theorem proved that gradient stable schemes are possible, and Eyre presented a framework for constructing gradient-stable, semi-implicit time steps for a given phase-field model. Here I present a new theorem that provides a broader class of gradient-stable steps, in particular ones in which the implicit part of the equation is linear. This enables use of fast Fourier transforms to solve for the updated field, providing a considerable advantage in speed and simplicity. Examples will be presented for the Allen-Cahn and Cahn-Hilliard equations, an Ehrlich-Schwoebel-type interface growth model, and block copolymers.

10:12AM A24.00012 Total energy and force calculations for correlated materials[1] , IVAN LEONOV, TP III, Center for Electronic Correlations and Magnetism, Uni Augsburg, Germany, VLADIMIR I. ANISIMOV, Institute of Metal Physics, Russian Academy of Sciences, Yekaterinburg, Russia, DIETER VOLLHARDT, TP III, Center for Electronic Correlations and Magnetism, Uni Augsburg, Germany — We present a computational scheme for the investigation of complex materials with strongly interacting electrons which is able to treat atomic displacements, and hence structural relaxation, caused by electronic correlations. It combines *ab initio* band structure and dynamical mean-field theory and is implemented with the linear response formalism regarding atomic displacements. We employ this approach to compute the equilibrium crystal structure and phase stability of a couple of correlated electron materials, such as elemental hydrogen, $SrVO_3$, and $KCuF_3$. Our results show an overall good agreement between the total energy and force computations of the equilibrium atomic position for these materials. The approach presented here allows one to study the structural properties of materials with strongly correlated electrons such as lattice instabilities observed at correlation induced metal-insulator phase transitions from first principles.

10:24AM A24.00013 Self-consistent implementation of the vector disordered local moment method for magnetic alloys and its applications to magnetic thermodynamics , KIRILL BELASHCHENKO, BHALCHANDRA PUJARI, University of Nebraska-Lincoln, PAUL LARSON, Colorado School of Mines, VLADIMIR ANTROPOV, Ames Laboratory, MARK VAN SCHILFGAARDE, King's College London — We describe an implementation of the coherent potential approximation within the LMTO formalism, which combines chemical and magnetic disorder treated within the vector disordered local moment model. It allows for arbitrary degree of magnetic order for Heisenberg spins specified by axially symmetric spin distribution functions. The atomic charges and potentials are determined self-consistently, and the transverse constraining fields are included as required by density functional theory. Total energies and spectral functions are available, and the spin distribution functions can be used as variational parameters to determine the magnetic state at the given temperature by minimizing the free energy. The performance of this method is illustrated using several examples. The predictions of the Curie temperatures by different approximations for several materials (such as Fe, Co, Gd, FePt, FePd, CoPt) are compared, including the effect of the constraining fields. We also discuss competing magnetic interactions in the $Fe_{1-x}Mn_xPt$ alloy, which is known from experiment to present five magnetic phases, including two noncollinear ones. We construct the magnetic phase diagram using the variational minimization of the free energy and obtain the correct sequence of phases.

10:36AM A24.00014 Large-scale Atomic Effective Pseudopotential Method for the Electronic Structure of Semiconductor Nanostructures , GABRIEL BESTER, R. CARDENAS, F. ZIRKELBACH, P.-Y. PRODHOMME, P. HAN, R. CHERIAN, Max-Planck-Institut für Festkörperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany — In the *Large-scale Atomic Effective Pseudopotential Method*, the Schrödinger equation of an electronic system is solved within an effective single-particle approach. *Atomic Effective Pseudopotentials* are utilized, which are derived from screened local effective crystal potentials obtained from self-consistent density functional theory calculations on elongated and slightly deformed bulk structures. A self-consistency cycle is not required, which reduces the computational effort. Furthermore, iterative solvers can be used to focus only on a few eigenstates of interest, e.g., states in the vicinity of the band gap of a semiconductor. Hence, this approach is particularly well suited for first-principles investigations of the electronic structure of nanostructures consisting of up to ten thousands of atoms, when the knowledge of the total energy of the system is not required. The treatment includes semi-local pseudopotentials (Kleinman Bylander separable form in real space) as well as the spin-orbit interaction. The obtained single-particle wavefunctions are then used to treat excited state properties by means of a configuration interaction approach. We will illustrate the capabilities of the method on some selected semiconductor nanostructures.

10:48AM A24.00015 Fidelity susceptibility of one-dimensional models with twisted boundary conditions[1] , DIPTIMAN SEN, MANISHA THAKURATHI, Indian Institute of Science, Bangalore, AMIT DUTTA, Indian Institute of Technology, Kanpur — It is well-known that the ground state fidelity of a quantum many-body system can be used to detect its quantum critical points (QCPs). If g denotes the parameter in the Hamiltonian with respect to which the fidelity is computed, we find that for one-dimensional models with a large but finite size, the fidelity susceptibility χ_F can detect a QCP provided that the correlation length exponent satisfies $\nu < 2$. We then show that χ_F can be used to locate a QCP even if $\nu \geq 2$ if we introduce boundary conditions labeled by a twist angle $N\theta$, where N is the system size. If the QCP lies at $g = 0$, we find that if N is kept constant, χ_F has a scaling form given by $\chi_F \sim \theta^{-2/\nu} f(g/\theta^{1/\nu})$ if $\theta \ll 2\pi/N$. We illustrate this in a tight-binding model of fermions with a spatially varying chemical potential with amplitude h and period $2q$ in which $\nu = q$. Finally we show that when q is very large, the model has two QCPs at $h = \pm 2$ which cannot be detected by studying the energy spectrum but are clearly detected by χ_F. The peak value and width of χ_F scale as non-trivial powers of q at these QCPs. We argue that these QCPs mark a transition between extended and localized states at the Fermi energy.

Session A25 GQI: Superconducting Qubits: Magnetic Flux and Vortex Noise on Qubits and Resonators, Quasiparticles, and Qubit-Resonator Designs 327 - Britton Plourde, Syracuse University

8:00AM A25.00001 Simulations of Noise in the 2D XY Spin Model[1] , CHUNTAI SHI, SUNGHO HAN, CLARE C. YU, Department of Physics and Astronomy, University of California Irvine — Experiments implicate spins on the surface of metals as the source of flux and inductance noise in SQUIDs. There is experimental evidence that interactions between these surface spins cannot be ignored. As a candidate model of the surface spins, we present Monte Carlo simulations of the classical 2D XY spin model on a square lattice. We investigate the magnetization noise as a function of frequency and temperature. Finite size effects are considered through studies of different size systems.

[1]This work is supported by Army Research Office Grant No. W911NF-10-1-0494.

8:12AM A25.00002 Surface spins in superconducting qubits: noise of noise and noise of inductance , ALEXANDER SHNIRMAN, PABLO SCHAD, BORIS NAROZHNY, GERD SCHOEN, Karlsruhe Institute of Technology — In the last several years a growing bulk of experimental evidence has emerged explaining the 1/f magnetic flux noise in superconducting circuits, e.g., qubits, by a very high density of paramagnetic impurities on the surfaces or interfaces of the superconducting metal. A theoretical picture of this phenomenon is still missing. Here we study a model of weakly interacting dissipative spins or spin clusters with the aim to determine their noise properties. In particular we compare the noise of noise (second spectrum) with the noise of the magnetic susceptibility measured as noise of inductance. Both of these were recently studied in experiments. We argue that the noise of noise is dominated by a simple gaussian background, whereas the noise of susceptibility can provide a hint about the microscopic nature of the spins. In particular we discuss the influence of the spin-spin interactions on the susceptibility noise.

8:24AM A25.00003 Experimental results on decoherence and readout of coupled superconducting flux qubits in a circuit-QED setup[1] , JEAN-LUC ORGIAZZI, DAVID LAYDEN, Institute for Quantum Computing, University of Waterloo, RYAN MARCHILDON, University of Toronto, MUSTAFA BAL, CHUNQING DENG, FLORIAN ONG, ADRIAN LUPASCU, Institute for Quantum Computing, University of Waterloo — We present the results of experiments with two superconducting flux qubits coupled to a high-quality factor aluminum coplanar waveguide resonator. The flux qubits have a loop area of ~ 24 μm^2. The coupling to the resonator is implemented using the inductance of a shared line. The qubits are independently controlled via on-chip fast flux bias lines. Readout is performed by homodyne detection at large resonator driving power. Readout contrast exceeds 70% for each qubit. We observed long relaxation times, approaching 10 microseconds. The coherence time at the symmetry point exceeds 1 microsecond. Away from the symmetry point, decoherence is due to $1/f$ flux noise, with a measured density of 2.6×10^{-6} Φ_0 $/\sqrt{\text{Hz}}$ at 1 Hz. We discuss the implementation of a two-qubit controlled-NOT gate using the selective darkening technique [1]. [1] P. C. de Groot, J. Lisenfeld, R. N. Schouten, S. Ashhab, A. Lupascu, C. J. P. M. Harmans, and J. E. Mooij. Nat. Phys., 6(10):763-766, October 2010.

8:36AM A25.00004 Ultrasensitive detection of magnetic field using a single artificial atom , MUSTAFA BAL, CHUNQING DENG, JEAN-LUC ORGIAZZI, FLORIAN ONG, ADRIAN LUPASCU, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo — We employ a single artificial atom to implement ultrasensitive magnetic field detection. The artificial atom is a persistent current qubit with a size in the micron range, which couples very strongly to magnetic field, with an equivalent magnetic moment of 3.8×10^5 Bohr magnetons. Sensitive detection is realized by employing the field-dependent coherent evolution of the artificial atom and high-fidelity quantum measurement, in a way similar to atomic magnetometry. Using an operation mode based on spin-echo manipulation and qubit reset by energy relaxation, we demonstrate a magnetic field detection sensitivity of $7.5\,pT/\sqrt{Hz}$ for an AC field at $10MHz$. The sensitivity is further improved if the reset step is eliminated and the correlation of consecutive projective measurements is used instead, reaching $3.3\,pT/\sqrt{Hz}$. The intrinsic sensitivity of this method to AC fields at frequencies in the $100\,kHz - 10\,MHz$ range compares favourably with DC-SQUIDs and atomic magnetometers of equivalent spatial resolution. More than an order of magnitude increase in sensitivity is possible using feasible improvements of qubit design and readout. This result illustrates the potential of artificial quantum systems for sensitive detection and related applications.

8:48AM A25.00005 Magnetic Field Effects on High Quality Factor Superconducting Coplanar Resonators , ANTHONY MEGRANT, CHARLES NEILL, RAMI BARENDS, YU CHEN, BEN CHIARO, JULIAN KELLY, MATTEO MARIANTONI, JOSH MUTUS, PETER O'MALLEY, DANIEL SANK, AMIT VAINSENCHER, JAMES WENNER, TED WHITE, DAVID LOW, SHINOBU OHYA, CHRISTOPHER PALMSTROM, JOHN MARTINIS, ANDREW CLELAND, UC Santa Barbara — Superconducting coplanar waveguide resonators have proven to be invaluable tools in studying some of the same decoherence mechanisms as those found in superconducting qubits. Prior improvements in fabrication led to resonator internal quality factors (Qi's) in excess of 10 million at high power, enabling us to sensitively probe environmental effects on the resonance frequency and Qi. We have found these resonators to be very susceptible to applied and stray magnetic fields, with measurable changes in the resonator's Qi and resonance frequency from fields as small as a few milligauss. I will present more recent measurements of resonators in magnetic fields.

9:00AM A25.00006 Effects of vortices trapped in superconducting microwave resonators , IBRAHIM NSANZINEZA, B.L.T. PLOURDE, Syracuse University — The microwave response of superconductors can be influenced by the presence of vortices and the dynamics they exhibit at high frequencies. We present measurements of vortices trapped in coplanar waveguide superconducting resonators fabricated from thin aluminum films, a common material for superconducting qubit circuits. In particular, by adjusting the geometry of our resonators we are able to trap only a few vortices in certain regions of the resonators. We perform field-cooled measurements to study the dependence of the microwave vortex response on magnetic field and frequency for various resonator modes. In most cases, the addition of vortices results in a downward shift in resonant frequency and a reduction in the quality factor. However, under certain circumstances, the presence of trapped vortices can actually lead to an enhancement of the resonator quality factor.

9:12AM A25.00007 Large kinetic inductance microwave resonators in magnetic field , MARTIN WEIDES, PHILIPP MAYER, FENGBIN SONG, SEBASTIAN PROBST, HANNES ROTZINGER, ALEXEY USTINOV, Karlsruhe Institute of Technology, Karlsruhe, Germany — Superconducting resonators of high quality factors are of great interest for photon detection and quantum computation. Conventionally, they operate in or close to the magnetic vacuum. However, for some circuits -for instance resonators coupled to spin ensemble crystals or Majorana fermions- the magnetic field is not negligible and the resonator's field robustness has to be well engineered. The magnetic field dependencies of resonance frequency and quality factor are of considerable interest to improve resonant quantum devices. In this presentation we will discuss thin film titanium nitride resonators operating in a homogeneous magnetic field. Titanium nitride has remarkably high internal microwave quality factors down to single photon levels, and a significant kinetic inductance contribution for thin film resonators. The microwave scattering data of frequency multiplexed resonators was taken in a Helium-3 refrigerator over a large range of photon number levels, temperatures, and magnetic fields. The resonators exhibit strong magnetic hysteresis effects in frequency and quality factor. The magnetic memory -caused by a spatial distribution of trapped vortices- is related to the resonator geometry.

9:24AM A25.00008 Flux-dependent loss in aluminum nanobridge SQUID resonators[1] , E. M. LEVENSON-FALK, R. VIJAY, I. SIDDIQI, QNL, UC Berkeley — Unlike traditional tunnel junctions, nanobridge Josephson junctions have weaker nonlinearity, higher transmittivity, and relatively few conduction channels. These parameters carry with them their own intrinsic loss mechanisms. In particular, quasiparticle trapping has been recently shown [1] to be prevalent in quantum point contact junctions operating in a similar parameter regime. We investigate losses in resonant circuits comprised of nanobridge SQUIDs. We observe an increase in loss and an anomalous frequency shift as the SQUIDs are flux-biased, which we speculate to be the result of quasiparticle trapping in a phase-biased nanobridge. We present detailed measurements of this effect, and discuss efforts towards eliminating it. [1] Bretheau et al., PRL 106, 257003 (2011)

9:36AM A25.00009 Random frequency modulation of a superconducting qubit , MATTI SILVERI, University of Oulu, JIAN LI, KARTHIKEYAN SAMPATH, JUHA-MATTI PIRKKALAINEN, ANTTI VEPSÄLÄINEN, WEI-CHENG CHIEN, Aalto University School of Science, JANI TUORILA, University of Oulu, MIKA SILLANPÄÄ, PERTTI HAKONEN, Aalto University School of Science, ERKKI THUNEBERG, University of Oulu, GHEORGHE PARAOANU, Aalto University School of Science — Superconducting circuits with Josephson junctions are a promising platform not only for developing quantum technologies, but, importantly, also for the study of effects that typically occur in complex condensed-matter systems. Here, we employ a transmon qubit to conduct an analog simulation of motional averaging, a phenomenon initially observed in nuclear magnetic resonance spectroscopy. To realize this effect, the flux bias of the transmon is modulated by a controllable pseudo-random telegraph noise, which results in stochastic jumping of the energy separation (frequency) between two discrete values. This can also be seen as a simulated fast-fluctuation environment under direct experimental control. Additionally, we discuss the population dynamics using an analytical master equation, and apply the motional averaging analysis on phenomena where the fluctuation of the energy is due to quasiparticles or to photon shot noise.

9:48AM A25.00010 Driven Dynamics and Rotary Echo of a Qubit Tunably Coupled to a Harmonic Oscillator , WILLIAM OLIVER, MIT Lincoln Laboratory, Lexington, Massachusetts, SIMON GUSTAVSSON, JONAS BYLANDER, FEI YAN, POL FORN-DIAZ, Massachusetts Institute of Technology, Cambridge, Massachusetts, VLAD BOLKHOVSKY, DANIELLE BRAJE, GEORGE FITCH, MIT Lincoln Laboratory, Lexington, Massachusetts, KHALIL HARRABI, The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama, Japan, DONNA LENNON, JOVI MILOSHI, PETER MURPHY, RICK SLATTERY, STEVEN SPECTOR, BEN TUREK, TERRY WEIR, PAUL WELANDER, MIT Lincoln Laboratory, Lexington, Massachusetts, FUMIKI YOSHIHARA, The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama, Japan, DAVID CORY, Institute for Quantum Computing and Department of Chemistry, University of Waterloo, Ontario, Canada, YASUNOBU NAKAMURA, The University of Tokyo, Komaba, Meguro-ku, Tokyo, Japan, TERRY ORLANDO, Massachusetts Institute of Technology, Cambridge, Massachusetts — We have investigated the driven dynamics of a superconducting flux qubit that is tunably coupled to a microwave resonator. We find that the qubit experiences an oscillating field mediated by off-resonant driving of the resonator, leading to strong modifications of the qubit Rabi frequency. This opens an additional noise channel, and we find that low-frequency noise in the coupling parameter causes a reduction of the coherence time during driven evolution. The noise can be mitigated with the rotary-echo pulse sequence, which, for driven systems, is analogous to the Hahn-echo sequence.

10:00AM A25.00011 Effect of environmental coupling on tunneling of quasiparticles in Josephson junctions[1] , MOHAMMAD ANSARI, University of Waterloo, FRANK WILHELM, Saarland University, URBASI SINHA, Raman Research Institute, ANINDA SINHA, Indian Institute of Science — We study quasiparticle tunneling in Josephson tunnel junctions embedded in an electromagnetic environment. We identify tunneling processes that transfer electrical charge and couple to the environment in a way similar to that of normal electrons, and processes that mix electrons and holes and are thus creating charge superpositions. The latter are sensitive for the phase difference between the superconductor and are thus limited by phase diffusion even at zero temperature. We show that that term is suppressed in many environments, thus leading to lower quasiparticle decay rates and thus better qubit coherence than previously expected.

[1]supported by NSERC, ODNI, IARPA

10:12AM A25.00012 Real-time measurement of quasiparticle tunneling in a single-junction transmon qubit using feedback[1] , DIEGO RISTÈ, NIELS BULTINK, MARIJN TIGGELMAN, RAYMOND SCHOUTEN, Kavli Institute of Nanoscience, Delft University of Technology, KONRAD LEHNERT, JILA, NIST and the University of Colorado, Boulder, LEONARDO DICARLO, Kavli Institute of Nanoscience, Delft University of Technology — With coherence times of superconducting qubits now exceeding $100\ \mu$s, the contribution of quasiparticle (QP) tunneling to qubit relaxation and dephasing becomes potentially relevant. We report the real-time measurement of QP tunneling across the single junction of a 3D transmon qubit. We integrate recent developments in projective qubit readout with 99% fidelity and feedback-based reset to transform the qubit into a charge-parity detector with $6\ \mu$s resolution. We detect a symmetric random telegraph signal matching a QP tunneling time of 0.8 ms. By measuring the correlation function of charge parity conditioned on specific initial and final qubit states, we determine that most QP tunneling does not induce qubit transitions, in contradiction with recent theory [1]. We extract a QP-induced qubit relaxation time $T_1^{\rm qp} \sim 3$ ms, decidedly not limiting the measured $T_1 = 0.14$ ms.

10:24AM A25.00013 Interfacing Superconducting Qubits and Resonator Qudit , FREDERICK STRAUCH, Williams College, XIAOTING WANG, KURT JACOBS, University of Massachusetts at Boston — We consider methods to transfer multi-qubit states into the higher-dimensional state space of a superconducting resonator, acting as a qudit. Several methods are proposed, using different combinations of resonant, dispersive, and auxiliary interactions. The complexity of such schemes are explored using analytical and numerically optimized control sequences. Extension to resonator measurement and qudit logic will be also be described.

10:36AM A25.00014 Frequency multiplexed dispersive readout of transmon qubits with the UCSB paramp , DANIEL SANK, UCSB, R. BARENDS, J. BOCHMANN, B. CAMPBELL, Y. CHEN, B. CHIARO, E. JEFFREY, J. KELLY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, A. VAINSENCHER, J. WENNER, T. WHITE, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — Our new Xmon qubit shows good coherence, controllability and simplified coupling to other circuit elements, making it a good candidate for a large scale quantum computer. Like all qubits, it requires high fidelity readout. To this end we have developed a new parametric amplifier circuit. Simplified input coupling of the amplifier allows straightforward interfacing with our frequency multiplexed dispersive readout circuitry. The amplifier features five different modes of pump power delivery, some of which allow us to reduce the microwave component count in our readout chain. We characterize our readout system using each of these modes of operation, as well as multi qubit readout.

10:48AM A25.00015 Engineering and control of coupled superconducting qubits arrays for quantum simulation[1] , E. HENRY, A. SCHMIDT, QNL, UC Berkeley, O. VIEHMANN, Ludwig-Maximilians-Universität, I. SIDDIQI, QNL, UC Berkeley — Superconducting qubit technology allows for engineering experimentally accessible, macroscopic quantum systems to arbitrary specifications within a large parameter space. By coupling multiple superconducting qubits in a periodic array, it is possible to fabricate physical objects which mimic the properties of naturally occurring systems not readily accessible to measurement or parameter variation, or theoretical systems not occurring in nature. We discuss design, fabrication, and measurement of a physical realization of the quantum Ising model in zero and one dimension. This is accomplished using a chain of identical transmon qubits acting as artificial spins whose interaction is dominated by nearest neighbor coupling. Control and readout of the system is accomplished by coupling only one of the artificial spins to a microwave resonator in a circuit QED architecture.

Session A26 GQI: Focus Session: Semiconductor Qubits - Optical Hybridization 328 - Thaddeus Ladd, HRL Laboratories, LLC

8:00AM A26.00001 Observation of quantum dot spin-photon entanglement , ATAC IMAMOGLU, ETH Zurich — Entanglement plays a central role in the burgeoning field of quantum information processing. A possible route towards a scalable architecture is provided by the concept of distributed quantum computation, based on small-scale few-qubit quantum processor nodes interconnected by single photon pulses. Generation of quantum correlated spin-photon pairs is a key step in such an approach. In this talk, we report the observation of quantum entanglement between a semiconductor quantum dot spin and the color of a propagating optical photon. The demonstration of entanglement relies on the use of fast single-photon detection which allows us to project the photon into a superposition of its two frequency components. Our results extend the previous demonstrations of single-spin photon entanglement in trapped ions, neutral atoms and nitrogen vacancy centers to the domain of artificial atoms in semiconductor nano-structures that allow for on-chip integration of electronic and photonic elements.

8:36AM A26.00002 Entanglement between a single quantum spin and a photon through ultra-fast frequency downconversion to telecom wavelengths , KRISTIAAN DE GREVE, Stanford University (currently at Harvard University), LEO YU, PETER MCMAHON, Stanford University, JASON PELC, Stanford University (currently at HP Labs, Palo Alto), CHANDRA NATARAJAN, NA YOUNG KIM, Stanford University, EISUKE ABE, Stanford University and NII, Tokyo, Japan, SEBASTIAN MAIER, CHRISTIAN SCHNEIDER, MARTIN KAMP, Universitaet Wuerzburg, SVEN HOEFLING, Stanford University and Universitaet Wuerzburg, ROBERT HADFIELD, Heriot-Watt University, ALFRED FORCHEL, Universitaet Wuerzburg, MARTIN FEJER, Stanford University, YOSHIHISA YAMAMOTO, Stanford University and NII, Tokyo, Japan — We demonstrate high-fidelity entanglement between a single InAs quantum dot electron spin, and the polarization of a spontaneously emitted single photon. With a magnetic field in Voigt geometry, the quantum dot's excited (trion) states are connected to the spin states in a lambda-configuration. We use these lambda-systems for all-optical spin manipulation, and spontaneous emission from one of the trion states gives rise to entanglement between both the polarization and color of the photon, as well as the spin state. Leakage of which-path information through e.g. the color of the photon obscures the spin-photon-polarization entanglement, which we overcome by a quantum erasure procedure. By time-resolved frequency conversion to a low-fiber-loss wavelength (1560 nm), we measure the photon arrival time with sub-10 ps resolution. Such ultrafast detection is inherently broadband, and incapable of distinguishing between the respective colors of the decay paths, providing the necessary quantum erasure. The conversion to 1560 nm also provides a means to extend the distance over which spin-photon entanglement can be maintained.

8:48AM A26.00003 Tomography of a high-fidelity spin-photon entangled state[1] , PETER MCMAHON, KRISTIAAN DE GREVE, LEO YU, JASON PELC, CHANDRA NATARAJAN, NA YOUNG KIM, EISUKE ABE, Stanford University, SEBASTIAN MAIER, CHRISTIAN SCHNEIDER, MARTIN KAMP, SVEN HOEFLING, Universitaet Wuerzburg, ROBERT HADFIELD, Heriot-Watt University, ALFRED FORCHEL, Universitaet Wuerzburg, M.M. FEJER, YOSHIHISA YAMAMOTO, Stanford University — The generation of entanglement between a quantum memory and a flying qubit is an important step towards building a quantum repeater node. Entanglement between a photon and a matter qubit has been demonstrated in several systems, including neutral atoms, trapped ions, NV centers and quantum dots. Quantum dots have a natural advantage that their radiative lifetimes are short, and therefore the rate of entanglement generation can be much faster than in other systems. We have recently demonstrated entanglement between an electron spin in a quantum dot, and the polarization of an emitted photon. In addition, the photon is converted to the low-loss 1550 nm band, which is important for implementing long-distance quantum communication systems. In this talk, I will present the reconstruction of the full density matrix of the entangled spin-photon state that we produce. We calculate the fidelity of the state from the density matrix, and conclude that it is $> 90\%$.

9:00AM A26.00004 Ultrafast downconversion quantum interface for a single quantum dot spin and 1550-nm single-photon channel , L. YU, J.S. PELC, K. DE GREVE, P.L. MCMAHON, M.M. FEJER, E. L. Ginzton Laboratory, Stanford University, Y. YAMAMOTO, E. L. Ginzton Laboratory, Stanford University and National Institute of Informatics, Tokyo, S. MAIER, C. SCHNEIDER, M. KAMP, S. HOFLING, A. FORCHEL, Technische Physik, Physikalisches Institut, Wilhelm Conrad Rontgen Research Center for Complex Material Systems, Universitat Wurzburg, C.M. NATARAJAN, R.H. HADFIELD, Scottish Universities Physics Alliance and School of Engineering and Physical Sciences, Heriot-Watt University — Long-distance quantum communication networks require appropriate interfaces between matter qubit-based nodes and low-loss photonic quantum channels. Quantum frequency conversion (QFC), whereby a photonic qubit's carrier frequency is translated while maintaining its quantum state, is well-suited to the task. Quantum dots have been studied extensively as potential quantum network nodes, but they do not emit indistinguishable single photons at telecomm wavelengths. We report an ultrafast, low-noise downconversion quantum interface, in which 910-nm single photons from a quantum dot are downconverted to the 1.5-μm lowest-loss telecom band, showing near-perfect preservation of antibunched photon statistics. Moreover, the resulting time resolution could also improve photon indistinguishability. Together with the III-V semiconductor quantum dot spin system, this ultrafast downconversion quantum interface provides new possibility to realize long-distance quantum communication networks.

9:12AM A26.00005 Observation of quantum entanglement between a photon and a single electron spin confined to an InAs quantum dot[1] , JOHN SCHAIBLEY, ALEX BURGERS, GREG MCCRACKEN[2], LUMING DUAN, PAUL BERMAN, DUNCAN STEEL, University of Michigan, ALLAN BRACKER, DANIEL GAMMON, Naval Research Lab, LU SHAM, University of California, San Diego — A single electron spin confined to a single InAs quantum dot (QD) can serve as a qubit for quantum information processing. By utilizing the QD's optically excited trion states in the presence of an externally applied magnetic field, the QD spin can be rapidly initialized, manipulated and read out. A key resource for quantum information is the ability to entangle distinct QD spins. One approach relies on intermediate spin-photon entanglement to mediate the entanglement between distant QD spin qubits. We report a demonstration of quantum entanglement between a photon's polarization state and the spin state of a single electron confined to a single QD. Here, the photon is spontaneously emitted from one of the QD's trion states. The emitted photon's polarization along the detection axis is entangled with the resulting spin state of the QD. By performing projective measurements on the photon's polarization state and correlating these measurements with the state of the QD spin in two different bases, we obtain a lower bound on the entanglement fidelity of 0.59 (after background correction). The fidelity bound is limited almost entirely by the timing resolution of our single photon detector. The spin-photon entanglement generation rate is 3×10^3 s^{-1}.

9:24AM A26.00006 A Spin Qubit Coupled to a Photonic Crystal Cavity , TIMOTHY SWEENEY, NRC postdoc at the Naval Research Lab, Washington, DC 20375, SAMUEL CARTER, NRL, MIJIN KIM, Sotera Defense Solutions, Annapolis Junction, MD 20701, CHUL SOO KIM, NRL, DMITRY SOLENOV, NRC postdoc at NRL, SOPHIA ECONOMOU, THOMAS REINEKE, NRL, LILY YANG, NRC postdoc at NRL, ALLAN BRACKER, DANIEL GAMMON, NRL — The development of a scalable light-matter quantum interface is an important goal of quantum information research. Photonic crystal (PC) membranes provide an architecture in which the interaction of photons with an optically active matter qubit can be controlled through the introduction of optical cavities and waveguides. Charge neutral quantum dots are commonly integrated into PC architectures and are useful for sources and switches, but do not demonstrate long-lived coherences. A charged quantum dot in a PC environment could lead to a spin-photon quantum interface, where it is the long-lived spin of the electron, not the exciton that serves as a qubit. We demonstrate optical spin initialization and coherent control of an electron in a quantum dot that is embedded in and coupled to a 2D PC membrane cavity. The PC membrane is incorporated into an asymmetric NIP diode that allows for charging of an InAs quantum dot via an applied bias. Resonant laser spectroscopy performed in a transverse magnetic field enables the optical measurement and initialization of the electron spin. Furthermore, with the introduction of detuned control pulses, we perform coherent rotations of the electron spin state. These studies demonstrate several essential accomplishments toward a spin-photon interface.

9:36AM A26.00007 Quantum Dots in H1 Photonic Crystal Microcavities for Quantum Information , JENNA HAGEMEIER, Physics Department, University of California Santa Barbara, USA, CRISTIAN BONATO, Huygens Laboratory, Leiden University, The Netherlands, TUAN-ANH TRUONG, Materials Department, University of California Santa Barbara, USA, HYOCHUL KIM, Physics Department, University of California Santa Barbara, USA, MORTEN BAKKER, GARETH J. BEIRNE, MARTIN P. VAN EXTER, Huygens Laboratory, Leiden University, The Netherlands, PIERRE PETROFF, ECE Department, University of California Santa Barbara, USA, DIRK BOUWMEESTER, Physics Department, University of California Santa Barbara, USA; Huygens Laboratory, Leiden University, The Netherlands — Coupling semiconductor quantum dots to optical microcavities is a promising technique for implementing quantum information processing protocols in the solid-state. By placing one or more emitters in a cavity, it is possible to create an efficient source of single photons or to explore collective interactions of few-emitter systems. Our devices consist of two layers of quantum dots, embedded in the cavity region of H1 photonic crystal microcavities. One of the quantum dot layers can be frequency-tuned deterministically, allowing two resonant quantum dots to be coupled to a single cavity mode. Because good mode-matching between the cavity mode and the input/output channel is necessary for many applications, we optimize the far-field profiles of our H1 cavities and demonstrate strong enhancement of the external mode matching properties. We will discuss our far-field optimization results as well as our ongoing work to study interactions of multiple emitters in a cavity.

9:48AM A26.00008 Dynamical effects of Stark-shifted quantum dots strongly coupled to photonic crystal cavities , KAUSHIK ROY CHOUDHURY, RANOJOY BOSE, EDO WAKS, Department of Electrical and Computer Engineering, IREAP, University of Maryland, College Park, Maryland 20742, USA — Single semiconductor quantum-dots (QDs) strongly coupled to photonic crystal cavities are a strong candidate for single photon generation, ultra-fast all optical switching and quantum information processing. Recent experiments on coupled-cavity quantum dot systems show possible manipulation of emission wavelength of the dot through optical Stark effect. Interesting dynamical features arise when the Stark pulse duration is comparable to QD-cavity interaction time. Here, we present a theoretical treatment of these dynamical effects and investigate dynamical emission spectrum, energy transfer and single photon generation. We study these effects through numerical solution of the full master equation. We demonstrate that dynamic Stark effects can be used to generate ultra-fast indistinguishable single photons using rapid Stark tuning of the quantum dot. The theoretical limit for the speed is shown to be faster than adiabatic rapid passage technique used for microwave photon generation in circuit QED. A systematic study of role of device parameters such as pulse-shape, dot-cavity coupling and incoherent losses on the efficiency and speed of single photon generation is also presented for possible experimental realization.

10:00AM A26.00009 Optical tuning of single quantum dots coupled to photonic crystal molecules using the optical Stark effect , RANOJOY BOSE, University of Maryland,College Park, KAUSHIK ROY, TAO CAI, University of Maryland, College Park, GLENN S. SOLOMON, NIST-Gaithersburg, and Joint Quantum Institute, University of Maryland, College Park, EDO WAKS, University of Maryland, College Park — The interaction of semiconductor quantum dots (QD) with photonic crystal resonator systems provides a highly integrated, solid-state platform for studies in ultra-low energy nonlinear optics and quantum optical phenomena. Here, we present a method to tune a semiconductor quantum dot (QD) all-optically into resonance with a cavity mode using the non-resonant optical Stark effect. We use a system comprised of two evanescently coupled photonic crystal cavities containing a single QD in one of the cavities. One mode of the coupled cavity system is used to generate a cavity-enhanced optical Stark shift, enabling the QD to be resonantly tuned to the other cavity mode. We show that the optical tuning of the QD results in a large radiative enhancement of the QD photon emission via the Purcell effect. We will further discuss dynamic experiments in the system using a Stark laser that has a time-duration on the order of the system decay rates. We will show that under this scenario, the cavity-QD spectrum provides a rich array of information on the system dynamics. The experiments are promising for a variety of applications in highly-efficient single photon generation, cavity quantum electrodynamics, ultra-fast optical switching, and classical and quantum information processing.

10:12AM A26.00010 Controlling interactions between coupled photonic crystal cavities using photochromic tuning , TAO CAI, RANOJOY BOSE, Department of Electrical Engineering, University of Maryland, College Park, GLENN SOLOMON, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology; National Institute of Standards and Technology, EDO WAKS, Department of Electrical Engineering, University of Maryland, College Park — Strongly coupled photonic crystal (PhC) resonator systems provide a promising platform for studying cavity quantum electrodynamics (QED) using semiconductor quantum dots (QDs). These device structures enable important applications such as photon blockade, quantum simulation, quantum-optical Josephson interferometer, and quantum phase transition of light. Many of these applications require the ability to accurately tune the resonant frequencies of individual cavities in the array, which provides a method to control their coupling interactions. This tuning method must be sufficiently local to address individual cavities spaced by less than 1 micron spatial separation. Here, we present a method for controlling the coupling interaction of photonic crystal cavity arrays by using a local and reversible photochromic tuning technique. By locally altering the refractive index of the photochromic material all-optically, the coupling interaction between two cavity modes could be modified over a tuning range as large as 700 GHz. By using this technique, we demonstrate the ability to couple photonic crystal cavities with a normal mode splitting of only 31.50 GHz. We further demonstrate that this tuning method can be extended to control the coupling interaction in larger cavity arrays.

10:24AM A26.00011 A qubit-photon controlled-NOT gate using a quantum dot strongly coupled to a cavity , HYOCHUL KIM, RANOJOY BOSE, THOMAS SHEN, University of Maryland, GLENN SOLOMON, Joint Quantum Institute, NIST, EDO WAKS, University of Maryland — Strong interactions between matter quantum bits (qubits) and photons play an essential role in quantum information. Quantum dots (QDs) provide a promising implementation of a matter qubit that can be strongly coupled to optical nanocavities, providing a direct light-matter interface. We use this light-matter interface to demonstrate a picosecond timescale controlled NOT logic gate between a QD and a photon, which is a fundamental building block for complex quantum logic. Coherent control of the QD qubit state by optical pulses results in a modification of cavity reflectivity, enabling a conditional bit-flip on the polarization state of a photon incident on the cavity.

10:36AM A26.00012 All-optical, arbitrary-basis initialization and readout of a diamond spin qubit[1] , C.G. YALE, B.B. BUCKLEY, D.J. CHRISTLE, F.J. HEREMANS, L.C. BASSETT, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106, G. BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — The nitrogen-vacancy (NV) center in diamond is a promising spin qubit candidate, in large part due to its optical addressability via a spin-selective intersystem crossing. Here we demonstrate a general all-optical technique to initialize and readout the NV spin state along an arbitrarily-chosen basis using coherent light fields[2] below 10 K, which negates the need for this special addressability. By tuning the NV center's excited-state structure to a lambda (Λ) configuration with a magnetic field, we use coherent population trapping (CPT) to initialize its spin into any desired superposition. We investigate the CPT time dynamics and use quantum state tomography to characterize the resultant state. We also demonstrate spin-state readout along an arbitrarily-chosen basis by measuring photoluminescence emitted during the transient period of the CPT interaction. Since these techniques do not rely on the intersystem crossing, they provide a pathway for all-optical control of other potential defect spin qubits, which may lack the NV center's unique structure.

10:48AM A26.00013 Defect qubit-nanophotonic structures based on silicon carbide[1] , G. CALUSINE, A. POLITI, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106 — Defect qubits in silicon carbide (SiC) have recently emerged as a promising alternative to the nitrogen vacancy center in diamond for applications in solid state quantum information technologies[2]. One common polytype of SiC, commonly referred to as 3C, is commercially available as a high quality single crystal epitaxial film grown on silicon substrates. We demonstrate that various techniques used to create, polarize, manipulate, and measure nitrogen vacancy centers can be similarly applied to defect spin qubits in 3C silicon carbide, even up to room temperature[3]. Additionally, we exploit 3C SiC's availability as a heteroepitaxial layer on silicon to incorporate these defect qubits into nanophotonic devices. We present the results of simulations and measurements on nano-fabricated optical devices incorporating defect qubits. These results demonstrate a promising route towards silicon carbide based hybrid light-matter quantum systems.

Session A27 GQI: Focus Session: Adiabatic Quantum Computing I 329 - Sergio Boixo, Information Sciences Institute, University of Southern California

8:00AM A27.00001 Adiabatic Quantum Computation with Neutral Atoms[1] , GRANT BIEDERMANN, Sandia National Laboratories — We are implementing a new platform for adiabatic quantum computation (AQC)[2] based on trapped neutral atoms whose coupling is mediated by the dipole-dipole interactions of Rydberg states. Ground state cesium atoms are dressed by laser fields in a manner conditional on the Rydberg blockade mechanism,[3,4] thereby providing the requisite entangling interactions. As a benchmark we study a Quadratic Unconstrained Binary Optimization (QUBO) problem whose solution is found in the ground state spin configuration of an Ising-like model.

8:36AM A27.00002 On scalable, universal adiabatic quantum computation , ARI MIZEL, Laboratory for Physical Sciences — We investigate scalable, universal adiabatic quantum computation. We exhibit a specific Hamiltonian of local one- and two-body interactions for which the ground state (a) yields the correct answer with high probability and (b) is provably fault-tolerant against local excitations. The effects of finite temperature are discussed.

8:48AM A27.00003 Ground State Spin Logic , JAMES WHITFIELD, University of Vienna, MAURO FACCIN, JACOB BIAMONTE, Institute for Scientific Interchange — Designing and optimizing cost functions and energy landscapes is a problem encountered in many fields of science and engineering. These landscapes and cost functions can be embedded and annealed in experimentally controllable spin Hamiltonians. Using an approach based on group theory and symmetries, we examine the embedding of Boolean logic gates into the ground-state subspace of such spin systems. We describe parameterized families of diagonal Hamiltonians and symmetry operations which preserve the ground-state subspace encoding the truth tables of Boolean formulas. The ground-state embeddings of adder circuits are used to illustrate how gates are combined and simplified using symmetry. Our work is relevant for experimental demonstrations of ground-state embeddings found in both classical optimization as well as adiabatic quantum optimization.

9:00AM A27.00004 Experimental signatures of quantum annealing[1] , SERGIO BOIXO, ISI - USC — Quantum annealing is a general strategy for solving optimization problems with the aid of quantum adiabatic evolution. How effective is rapid decoherence in precluding quantum effects in a quantum annealing experiment, and will engineered quantum annealing devices effectively perform classical thermalization when coupled to a decohering thermal environment? Using the D-Wave machine, we report experimental results for a simple problem which takes advantage of the fact that for quantum annealing the measurement statistics are determined by the energy spectrum along the quantum evolution, while in classical thermalization they are determined by the spectrum of the final Hamiltonian only. We establish an experimental signature which is consistent with quantum annealing, and at the same time inconsistent with classical thermalization, in spite of a decoherence timescale which is orders of magnitude shorter than the adiabatic evolution time. For larger and more difficult problems, we compare the measurements statistics of the D-Wave machine to large-scale numerical simulations of simulated annealing and simulated quantum annealing, implemented through classical and quantum Monte Carlo simulations. For our test cases the statistics of the machine are - within calibration uncertainties - indistinguishable from a simulated quantum annealer with suitably chosen parameters, but significantly different from a classical annealer.

[1]Work in collaboration with T. Albash, N. Chancellor, S. Isakov, D. Lidar, T. Roennow, F. Spedalieri, M. Troyer and Z. Wang.

9:36AM A27.00005 Benchmarking the D-Wave adiabatic quantum optimizer via 2D-Ising spin glasses , ZHIHUI WANG, SERGIO BOIXO, TAMEEM ALBASH, DANIEL LIDAR, Universiy of Southern California — We present results on benchmarking the D-Wave One quantum optimizer chip using random 2D Ising spin problems. Finding the ground state of the 2D Ising model with randomly assigned local fields and couplings is NP-hard. The chip attempts to find the ground state via quantum annealing, interpolating between a transverse field and the final Ising Hamiltonian. The experimentally obtained final states are checked against exact results and the performance of the chip is characterized by the probability of finding the ground state and the estimated annealing time for finding the ground state with high probability. By analyzing results for 8 to 108 spins, the scaling of the estimated annealing time as a function of the number of spins is compared with the computation time required by classical solvers. The correlation between classical and quantum hardness is also studied. Furthermore, we analyze the correlation between the experimental success probability and the minimum energy gap during the quantum annealing, as well as the interplay between the adiabatic condition and thermalization.

9:48AM A27.00006 Using coupling strength to tell apart experimental quantum annealing and classical thermalization models , MILAD MARVIAN, SERGIO BOIXO, TAMEEM ALBASH, DANIEL LIDAR, University of Southern California — Working with a two-qubit Ising Hamiltonian as the target Hamiltonian of quantum annealing implemented on a D-Wave One chip, we study how the qubit-qubit coupling strength affects the probability of finding the ground state. We solve the same problem analytically and numerically using classical thermalization models, and discuss conditions under which the classical prediction for the ground state probability, as a function of coupling strength, differs from the experimental results. For certain reasonable noise models this allows us to tell apart quantum annealing and classical thermalization.

10:00AM A27.00007 Computational performance and scaling of adiabatic quantum annealing processors[1] , TROELS FRIMODT RØNNOW, SERGEI ISAKOV, Institut f. Theoretische Physik, ETH Zürich, DAVE WECKER, Microsoft Corporation, SERGIO BOIXO, Center for Quantum Information Science & Technology - Information Sciences Institute, MATTHIAS TROYER, Institut f. Theoretische Physik, ETH Zürich — We characterise the recent 128 qubit quantum annealing processor, D-Wave One, through investigation of hardness and scaling of "time-to-solution" for several thousand realisations of $\pm J$ spin glass problems, ranging from 8 to 108 qubits in size. We compare statistics of the results to classical- and simulated quantum annealing. Within the processors noise and calibration uncertainties, we find that the results generated by the D-Wave One are statistically indistinguishable from results generated by a simulated quantum annealer while significantly different from those of a classical annealer. An intriguing feature is strong bimodal separation of the instances into two categories: hard and easy. This feature is not observed for the classical annealer. Based on the similarities between the simulated quantum annealer and D-Wave One, we make predictions for the 512 qubit processor, D-Wave Two.

10:12AM A27.00008 Error correction in adiabatic quantum computation , KEVIN YOUNG, MOHAN SAROVAR, ROBIN BLUME-KOHOUT, Sandia National Laboratories, SANDIA NATIONAL LABORATORIES TEAM — In conventional quantum computing models (e.g. the circuit-model) it is well understood that error suppression techniques by themselves are insufficient for fault-tolerant quantum computing. From a thermodynamic perspective this is because error suppression alone does not provide a mechanism to remove the entropy generated by errors from the encoded system . Since the thermodynamic argument is independent of the computational model it is expected that error suppression alone is insufficient for fault-tolerant quantum computing in the adiabatic quantum computing (AQC) model also. In this talk we provide a scheme for performing error correction for AQC and discuss the differences between our method and those used in quantum circuit model implementations.

10:24AM A27.00009 Experimental Quantum Error Correction , KRISTEN PUDENZ, DANIEL LIDAR, University of Southern California — We demonstrate an experimentally implemented quantum error correcting code (QECC) in an adiabatic quantum computation (AQC) setting. In AQC, the computation proceeds by slowly changing the controls of the system to move from an initial Hamiltonian with an easily prepared ground state to a final Hamiltonian whose ground state embodies the solution to the problem. Our QECC is a repetition code in the computational basis, and encodes the final Hamiltonian of the computation. In this way, we provide an energy penalty for excursions outside the codespace which increases as the AQC progresses. We supplement this with classical decoding of the results at the end of the computation, so that the computation may finish in a state other than the ground state and still solve the problem, as long as it stays within the low-lying spectrum of decodable states. We will show experimental results demonstrating that AQCs encoded with our QECC exhibit better success rates than both unencoded and classically encoded versions.

10:36AM A27.00010 Adiabatic quantum computational properties of Hopf link , OMAR SHEHAB, University of Maryland, Baltimore County — Topological quantum computation has recently become an active field of research with a promise of tackling decoherence. Another track of research effort has presented adiabatic quantum computation as a candidate for implementing quantum computers with presently available technologies. We investigate the potential of combining the strengths of both regime. This report conducts adiabatic evolution on low dimensional topological constructs. We study the properties of a Hopf link related to adiabatic quantum computation. The graph and Seifert surface for the link are calculated. The Ising model representing the Hopf link is then derived from the surface. The Edwards-Anderson Hamiltonian is also solved for the Ising model. The associated eigenfunction and eigenvalues are then used to investigate computational problems which can be represented by the ground state of the adiabatic Hamiltonian. We also consider a type II Reidemeister move on the link. The graph and Seifert surface are calculated for the new link. Then the Edwards-Anderson Hamiltonian is solved for the associated Ising model. The constraints of adiabatic evolution are calculated for both cases. Finally, computational problems are investigated which can be represented by the ground state of the adiabatic Hamiltonian.

10:48AM A27.00011 Symmetry and Controllability for Quantum Spin Networks , XIAOTING WANG, University of Massachusetts at Boston, SOPHIE SCHIRMER, Swansea University, DANIEL BURGARTH, Aberystwyth University, PETER PEMBERTON-ROSS, University of Basel, KURT JACOBS, University of Massachusetts at Boston — Symmetry is found to be an important tool to study the controllability problems in quantum control. Based on quantum spin networks subject to control of a single node by a local potential (Z-control), we have considered the relation of symmetriy and subspace controllability. Focusing on the single excitation subspace it is shown that for single-node Z-controls external symmetries are characterized by eigenstates of the system Hamiltonian that have zero overlap with the control node, and there are no internal symmetries. For uniformly coupled XXZ chains a characterization of all possible symmetries is derived from Bethe ansatz. Moreover, for uniform Heisenberg and XX chains, basic number theory can be used to prove that the lack of symmetry is equivalent to subspace controllability. On the other hand, symmetries in the Hamiltonian can be classified into two types: the internal and the external symmetries. Based on the external symmetries, we can rigorously prove the subspace controllability in each of the invariant subspaces for both XXZ and XYZ chains, but not for XX or Ising chains. All these results are useful to design the appropriate control strategy when implementing QIP in real physical systems.

Session A28 Focus Session: Statistical Physics of Active Systems Away from Detailed Balance

336 - Aparna Baskaran, Brandeis University

8:00AM A28.00001 Motility-Induced Phase Separation in Active Matter: a generic formalism for active brownian particles and run-and-tumble particles , JULIEN TAILLEUR, CNRS - Université Paris Diderot — In this talk I will show that several classes of active particles admit an identical coarse-grained description in terms of fluctuating hydrodynamic fields. This equivalence holds as long as the microscopic parameters (e.g. swim speed v, diffusivity or tumbling rate), that may be spatially varying, depend on the local density ρ of particles but not on their orientation. This equivalence can thus extend to interacting particles and shows that motility-induced phase separation is generic in these systems: a steeply enough decreasing $v(\rho)$ generates phase separation in dimensions d=1,2,3. I will discuss the consequences of this phenomenon for pattern formation in bacterial colony and effective temperatures in Active Matter.

8:36AM A28.00002 Defect Interactions in Active Nematics[1] , XU MA, MARK J. BOWICK, Syracuse Univ., LUCA GIOMI, Harvard Univ., M. CRISTINA MARCHETTI, Syracuse Univ. — Topological defects play prominent roles in passive nematic systems, but defect-antidefect pairs ultimately attract and annihilate in a finite time as the system coarsens and approaches its uniform ground state. The situation changes in active systems, which generate energy at the level of the microscopic constituents. We discuss analytic and numerical studies of two-dimensional active nematics focusing on the ability of activity to generate both defect production and annihilation and to stabilize defect-antidefect pairs at arbitrarily long times. In particular we analyze the dynamics of defect pair annihilation as a function of activity and friction and compare to experimental systems consisting of active bundled microtubule suspensions.

[1]This work was supported by the NSF through grants DMR-1004789 and DMR-0808812 and by the Syracuse Soft Matter Program.

8:48AM A28.00003 Structure and Dynamics of a Phase-Separating Active Colloidal Fluid , GABRIEL REDNER, MICHAEL HAGAN, APARNA BASKARAN, Brandeis University — We examine a minimal model for an active colloidal fluid in the form of self-propelled Brownian spheres that interact purely through excluded volume. Despite the absence of an aligning interaction, this system shows the signature behaviors of an active fluid, including anomalous number fluctuations and phase separation. Using simulations and analytic modeling, we quantify the phase diagram and separation kinetics. We show that this nonequilibrium active system undergoes an analog of an equilibrium continuous phase transition, with a critical point and a binodal beneath which the system separates into dense and dilute phases whose concentrations depend only on activity. The dense phase is a unique material that we call an active solid, which exhibits the structural signatures of a crystalline solid near the crystal-hexatic transition point, and anomalous dynamics including superdiffusive motion on intermediate timescales.

9:00AM A28.00004 Thermally Active Colloids , JACK COHEN, RAMIN GOLESTANIAN, University of Oxford, Theoretical Physics — We present a model of thermally active colloids that can propel and act as heat sources through absorption of light. We study the resulting dynamics of a system of many of these interacting colloids. The interplay between light absorption, long range fields and diffusion leads to novel collective dynamics.

9:12AM A28.00005 Active Colloids, a new building block for smarter materials , JEREMIE PALACCI, CSMR, NYU — Self-propelled micro-particles are intrinsically out-of-equilibrium. This renders their physics far richer than that of passive colloids while relaxing some thermodynamical constraints and give rise to the emergence of complex phenomena e.g. collective behavior, swarming... I will present a new form of self-assembly originating from non-equilibrium driving forces. When activated by light, a set of new self-propelled particles spontaneously assemble into *living crystals* which form, break, explode and reform somewhere else. We will show that this complex dynamics originates in the competition between self-propulsion of the particles attractive interactions induced respectively by osmotic and phoretic effects. The particles can moreover be steered by an external magnetic field. Light activated and steerable self propelled particles new perspectives in the design and the properties of smarter materials.

9:48AM A28.00006 Asymmetric gears in a bacterial bath: Crossover between equilibrium and active motion[1] , AYHAN DUZGUN, JONATHAN SELINGER, Kent State University — A fundamental distinction between active matter and equilibrium systems is that active matter is not governed by the conventional laws of thermodynamics. As a specific example, recent experiments have put asymmetric gears into a "bacterial bath," in which bacteria consume food, propel themselves forward, collide into the gears, and induce asymmetric rotation, thus converting chemical energy into mechanical work (Sokolov et al, 2010). By comparison, the same gears would not rotate in a thermal bath, because the second law of thermodynamics prohibits converting equilibrium thermal energy into mechanical work. This experiment leads to the basic question of what makes the difference between self-propelled motion and equilibrium thermal motion. To address this question, we perform simulations of a gear in a bacterial bath, following the approach of Angelani et al (2009); these simulations confirm that bacterial motion leads asymmetric rotation. We then modify the equations of motion, interpolating between bacteria and equilibrium Brownian particles, and determine the motion of the gear. These results help to identify what features of active bacterial motion are necessary to violate the laws of thermodynamics and generate rotation, and how these features can be controlled.

[1]This work was supported by NSF DMR-1106014.

10:00AM A28.00007 Microfluidic ratchets: from bacterial separation to sperm guidance[1] , CARLOS CONDAT, IVAN BERDAKIN, VERONICA MARCONI, IFEG-CONICET and FaMAF-Universidad Nacional de Cordoba, Cordoba, Argentina, ALEJANDRO GUIDOBALDI, LAURA GIOJALAS, CEBICEM - CONICET and FCEFyN -Universidad Nacional de Cordoba, Cordoba, Argentina, ALEJANDRO SILHANEK, Department of Physics, University of Liege, Liege, Belgium, YOGESH JEYARAM, VICTOR MOSHCHALKOV, Institute of Nanoscale Physics and Chemistry, Katholieke Universiteit Leuven, Leuven, Belgium, LYN VENKEN, JOZEF VANDERLEYDEN, Faculty of Bioscience Engineering, Katholieke Universiteit Leuven, Leuven, Belgium — It has been shown that a suitably built asymmetric microdevice can be used to separate and select self-propelled microorganisms. The efficiency of this rectification effect depends on the detailed dynamics of the individual microorganism. In the case of run-and-tumble bacteria we show that the distribution of run lengths and the partial preservation of run orientation memory through a tumble are important factors when computing the rectification efficiency. In addition, we show that this ratchet effect can be used to separate or concentrate sperm cells. Using a simple phenomenological model we optimize the geometry of the confining habitat in order to accumulate the cells. Both swimming strategy and swimmer size should be taken into account to optimize the design of a micro-patterned architecture for a device that can be used for effective physical bacterial separation or sperm guidance.

[1]We acknowledge support from UNC, MINCyT and CONICET, Argentina, and FWO and KUL, Belgium.

10:12AM A28.00008 Establishing the Turing mechanism using synthetic cells , CAMILLE GIRABAWE, NATHAN TOMPKINS, NING LI, Brandeis University, G. BARD ERMENTROUT, University of Pittsburgh, IRVING R. EPSTEIN, SETH FRADEN, Brandeis University — In 1952 Alan Turing published his seminal pape *The Chemical Basis of Morphogenesi* in which he described a basis for physical morphogenesis due solely to a reaction-diffusion system. His mechanism has been tested extensively but remains controversial and not fully demonstrated for cellular systems. Now 60 years after its debu, we describe an experimental system that demonstrates all six of his phenomenological predictions with additional support that these observations are due specifically to the Turing mechanism itsel. Further we demonstrate a nonlinear phenomena in the same system that was not predicted by Turing and which is not explained by a linear solution analysis of the governing system equations. Finally we also demonstrate that this system undergoes chemical and physical morphogenesis as Turing suggeste.

10:24AM A28.00009 Do Ion Channels Spin? , ROBERT SHAW, None — Ionic current flowing through a membrane pore with a helical architecture may impart considerable torque to the pore structure itself. If the channel protein is free to rotate, it will spin at significant speeds. Order of magnitude estimates of possible rotation rates are presented, as well as a few arguments why such motion could improve ion transport.

10:36AM A28.00010 Interactions Between Flocks and Obstacles , PEARSON MILLER, Department of Physics, Yale University, NICHOLAS OUELLETTE, Department of Mechanical Engineering & Materials Science, Yale University — The collective behavior of interacting active particles has generated considerable interest in recent years. Many models for such behavior have been proposed, ranging from simple systems of discrete particles with ad hoc interaction rules to continuum models with assumed interaction potentials to complex, bio-inspired models of collective animal motion. But in almost all cases, the resulting emergent behavior is studied in isolated systems far from boundaries. In contrast, we present results from a computational study of a simple discrete flocking model in the presence of obstacles. We consider both the behavior of the system in restricted domains bounded by solid walls and the scattering of developed flocks off of stationary targets, and discuss discuss the relationship of our results to liquid and granular systems.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A29 DCMP: Three Dimensional Topological Insulators: Chalcogenides 337 - Cihan Kurter, University of Illinois

8:00AM A29.00001 Superconductivity in a topological insulator Sb_2Te_3[1] , LUKAS ZHAO, HAIMING DENG, MILAN BEGLIARBEKOV, INNA KORZHOVSKA, ZHIYI CHEN, JEFFREY SECOR, LIA KRUSIN-ELBAUM, CCNY — We report an observation of superconductivity in a topological material Sb_2Te_3 synthesized under modest pressure ($\sim$ 5.5 MPA) that has the zero-field superconducting transition temperature $T_c = 8.3$ K – the highest among any topological systems reported thus far. High resolution TEM and XRD Rietveld refinement analysis of the superconducting crystals show that while there is a 0.2% elongation of the lattice parameter in the *c*-direction, the rhombohedral van der Walls unit cell structure is preserved. The upper critical field H_{c2} anisotropy is surprisingly small, only ~ 1.5, much smaller than the crystalline anisotropy of ~ 8. This anisotropy appears consistent with the paramagnetically limited critical field, given the reported large value (~ 10) of the *g*-factor. The diamagnetic state of this new superconductor is also unusual, since even in the normal state the system supports large orbital currents. We will discuss our observations in the context of topological superconductivity and Dirac energy-momentum dispersion of the surface states.

[1]Supported in part by NSF-DMR-1122594

8:12AM A29.00002 $Bi_{1-x}Sb_x$(110): A non-closed packed surface of a topological insulator , LUCAS BARRETO, WENDELL SIMOES E SILVA, MALTHE STENSGAARD, SØREN ULSTRUP, MARCO BIANCHI, XIE-GANG ZHU, MATTEO MICHIARDI, MACIEJ DENDZIK, PHILIP HOFMANN, Department of Physics and Astronomy, Aarhus University, Denmark — Topological insulators are characterised by an insulating bulk band structure, but topological considerations require their surfaces to support gap-less, metallic states. Meanwhile, many examples of such materials have been predicted and found experimentally, but experimental effort has concentrated on the closed-packed (111) surface of these materials. Thus, the theoretical picture of an insulating bulk embedded in a metallic surface from all sides of a crystal still needs to be confirmed. Here we present angle-resolved photoemission spectroscopy results from the (110) surface of the topological insulator $Bi_{1-x}Sb_x$ ($x \approx 0.15$). The observed band structure and Fermi contour are in excellent agreement with theoretical predictions and slightly different from the electronic structure of the parent surface Bi(110), in particular around the X_1 time-reversal invariant momentum. We argue that the preparation of surfaces different from (111) opens the possibility to tailor the detailed electronic structure and properties of the topological surface states.

8:24AM A29.00003 Mass acquisition of Dirac fermions in the presence of magnetic doping in the topological insulator Sb_2Te_3 , YEPING JIANG, CNAM, University of Maryland, ZHI LI, CANLI SONG, KE HE, LILI WANG, Institute of Physics, CAS, XI CHEN, Department of Physics, Tsinghua University, XUCUN MA, Institute of Physics, CAS, QIKUN XUE, Department of Physics, Tsinghua University — The nontrivial bulk band topology and time reversal symmetry yield gapless surface states in three dimensional topological insulators. The gapless nature of surface states in strong topological insulator is predicted to be violated by time-reversal-symmetry breaking perturbations, which opens back-scattering channels between Kramers pairs and induces a massive gap near the Dirac point of surface states. Such a massive Dirac fermion system gives rise to an unconventional magnetoelectric response relating to many exotic phenomena such as half-quantized anomalous Hall effect, topological quantized magnetoelectric effect and even the magnetic monopole. Here we introduce time-reversal-symmetry breaking by doping Cr atoms into the topmost quintuple layer or into the bulk of Sb_2Te_3 thin films. We demonstrate for the first time by Landau level spectroscopy the deviation of zero modes, which indicates the acquirement of a mass term in the presence of surface or bulk magnetic doping. We also show that the magnitude of the mass term in the surface states depends on both the Cr doping level and the magnetic field, offering a new way of measuring the doping- and field-dependence of local magnetization of dopants. Our observation suggests Cr-doped Sb_2Te_3 is a promising candidate for realization of proposed novel magnetoelectric effects.

8:36AM A29.00004 ABSTRACT WITHDRAWN –

8:48AM A29.00005 Possible topological insulating state in bismuth doped with arsenic: magneto-optical study , G.M. FOSTER, S.V. DORDEVIC, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, M.V. NIKOLIC, Institute for Multidisciplinary Research, University of Belgrade, S.S. VUJATOVIC, Z.Z. DJURIC, P.M. NIKOLIC, Serbian Academy of Sciences and Arts, Z. CHEN, Z.Q. LI, National High Magnetic Field Laboratory, Tallahassee — Bismuth and its alloys with antimony have attracted attention in recent years due to possible realization of topological insulating state. In this study we have used infrared and magneto-optical spectroscopies to probe the electrodynamic response of bismuth doped with 1.0 % of arsenic. The spectra will be presented for temperatures down to 5 K, and in magnetic fields as high as 18 Tesla. The results reveal strong magneto-optical activity, especially around the plasma minimum in reflectance. These findings will be compared and contrasted with magneto-optical results on topological insulator $Bi_{1-x}Sb_x$.

9:00AM A29.00006 Exotic magnetic properties of diluted magnetic binary chalcogenides , MAIA G. VERGNIORY, Max Planck Institute of Microstructure Physics, XABIER ZUBIZARRETA, Max Planck Institute of Microstructure Physics, 06120 Halle, Germany, MIKHAIL M. OTROKOV, Tomsk State University, 634050 Tomsk, Russia, IGOR V. MAZNICHENKO, JÜRGEN HENK, Institut für Physik, Martin-Luther-Universität Halle-Witternberg, 06009 Halle, Germany, EVGUENI V. CHULKOV, Donostia International Physics Center, 20018 Donostia-San Sebastian, Spain, ARTHUR ERNST, Max Planck Institute of Microstructure Physics, 06120 Halle, Germany — Using first-principles Green function approach we studied electronic and magnetic properties of diluted magnetic binary chalcogenides A_2B_3, doped with transition metals substituing the A element. The electronic structure of the impurities in the chalcogenides is mainly featured by the crystal field splitting. We found that two main mechanisms are responsible for long-range magnetic order in these materials: hole mediated magnetism within the layer of A atoms and indirect interaction between magnetic moments via a B atom. We also estimated Curie temperature of these systems, which was found in good agreement with the available experimental data. Our results shed light on the understanding of magnetic interaction and control in toplogical insulators.

9:12AM A29.00007 Magneto-transport properties of the ternary topological insulator $(Bi_{0.5}Sb_{0.5})_2Te_3$ in the presence of electrostatic gating and magnetic impurity , LIUQI YU, JORGE BARREDA, LONGQIAN HU, P. XIONG, Department of Physics, Florida State University, USA, TONG GUAN, XIAOYUE HE, K. WU, Y. LI, Institute of Physics, Chinese Academy of Sciences, China — A three-dimensional topological insulator, $(Bi_{0.5}Sb_{0.5})_2Te_3$, is used to characterize the electronic properties of the spin helical conducting surface state. Epitaxial films are grown via MBE on (111) $SrTiO_3$ substrate, which serves as the gate dielectric. Magnetoresistance (MR) and Hall effect measurements have been performed at various back gate voltages. Ambipolar field effect has been observed, enabling effective tuning of the Fermi level across the band gap. Weak antilocalization effect is identified and used to differentiate the surface state. The Hikami-Larkin-Nagaoka (HLN) equation is used to analyze the MR data and the results show the top and bottom surfaces become decoupled when the Fermi level is in the bulk band gap. We also examine the effects of paramagnetic impurity (MI), which introduces time reversal symmetry breaking scattering, on the TI surface states. Taking advantage of the unique capability of *in situ* deposition in a customized dilution refrigerator, paramagnetic Cr atoms were incrementally quench-condensed onto the sample surface and transport measurements were performed at each MI density. The procedure eliminates any sample-to-sample variation and complications from air exposure. Pronounced changes in the weak antilocalization effect and the sample carrier density with increasing MI concentration were observed. Possible origins of these observations will be discussed.

9:24AM A29.00008 Visualizing Landau levels of Dirac electrons in Bi_2Te_3 in a one dimensional potential , DANIEL WALKUP, YOSHINORI OKADA, WENWEN ZHOU, CHETAN DHITAL, YING RAN, ZIQIANG WANG, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — When a magnetic field is applied to a solid, the electrons fall into discrete, highly degenerate Landau levels. In each Landau level the wavefunction has a certain characteristic spread, which increases with the energy (index) of the level. This has important physical consequences especially in the presence of spatial inhomogeneity. Using scanning tunneling spectroscopy, we have examined the Dirac electrons on Bi_2Te_3 under a magnetic field and subject to a smooth one-dimensional periodic potential. We find that the lowest Landau levels track the potential variation, but the higher levels are more homogeneous. Through a calculation of the Landau level wavefunctions, we form a coherent picture of how their spread interacts with the potential landscape, explaining the experimental data. Our findings have important implications for transport and magneto-resistance measurements in Dirac materials with engineered potential landscapes.

9:36AM A29.00009 Topological States Ruled by Stacking Faults in Bi_2Se_3 and Bi_2Te_3[1] , LEANDRO SEIXAS, LEONARDO ABDALLA, Universidade de Sao Paulo, TOME SCHMIDT, Universidade Federal de Uberlandia, ADALBERTO FAZZIO, Universidade de Sao Paulo, ROBERTO MIWA, Universidade Federal de Uberlandia — Extended defects like stacking faults (SF) can originate topologically protected metallic states in bulk topological insulators (TI). These induced topological states are a response to the weakening of the inter-layer van der Waals interactions due to the SF defect. In TI thin films the degeneracy of Dirac bands of opposite surfaces can be lifted upon the formation of SF defects. Such slab asymmetry can promote a net spin current, absent of backscattering processes, in thin film made of TIs. These results have been obtained by fully relativistic first principles calculations.

[1]The authors acknowledge financial support from CNPq/INCT, CAPES, FAPEMIG, and FAPESP, and the computational support from CENAPAD/SP.

9:48AM A29.00010 Proximity effect in MBE grown bismuth chalcogenide thin films[1] , BRIAN MULCAHY, MAO ZHENG, CAN ZHANG, ALLISON DOVE, ZACHARY R. YOSCOVITS, GUSTAF OLSON, JAMES N. ECKSTEIN, University of Illinois at Urbana-Champaign — Topological insulators (TIs) comprise a new state of matter which provides access to novel physics. Of the set of materials that have exhibited spectroscopic evidence of topologically protected surface states, bismuth chalcogenide systems have garnered particular interest due to their relatively large nominal bulk band gap and single Dirac cone near the Fermi surface. We are studying the superconducting proximity effect in MBE grown thin films of Bi_2Se_3, Bi_2Te_3, and ternary compounds. After *in situ* deposition of a low temperature superconductor, the films are patterned into devices containing a matrix of superconducting islands of tunable size and density on top of the TI layer. We discuss growth optimization, device processing, the role of the superconductor-TI interface, and proximity effect transport results.

[1]This work is supported by the NSF.

10:00AM A29.00011 Topological phase transition induced by atomic displacements in PbS and PbTe , JINWOONG KIM, Dept. of Physics, POSTECH, SEUNG-HOON JHI, Dept. of Physics and Division of Advanced Materials Science, POSTECH — Discovery of 3D topological insulator initiates exploration of finding new materials having topological insulating phase or mechanisms for topological phase transitions. Introducing interactions or strains into non-interacting electron systems, for example, can produce non-trivial topological phases in them otherwise having trivial band insulating phase at equilibrium conditions. Using first-principles methods, we study emerging topological phases in band insulating PbS and PbTe, which are induced by selective atomic displacements. Phonon modes corresponding to the displacements are identified and conditions of inducing the topological phase transition are suggested. We show that surface states develop flickering Dirac cones at band-inversion k-points upon dynamic atomic displacements with sufficient amplitude. Our results demonstrate that elementary excitation modes like phonon can induce topological phases in trivial band insulators.

10:12AM A29.00012 Optical selection rules for electron-hole pair excitation in 3D topological insulators , HARI PAUDEL, MICHAEL LEUENBERGER, University of Central Florida — Experiments using ARPES, which is based on the photoelectric effect, have shown that the surface states in 3D topological insulators (TI) are helical. Here we consider Weyl interface fermions due to band inversion in narrow-bandgap semiconductors, such as $Pb_{1-x}Sn_xTe$ and $Bi_{1-x}Sb_x$. We determine the optical selection rules of electron-hole pair (EHP) excitation by means of the solutions of the 3D Dirac equation. While EHPs in graphene are generated through intraband transitions, we show that in 3D TI they are generated through both intraband and interband transitions. For their analysis, we calculate explicitly the electric dipole matrix elements by means of bandstructure calculations for $Pb_{1-x}Sn_xTe$. We will introduce a spin helicity operator in 3D TI. Our results are crucial for future opto-spintronic devices based on 3D TI.

10:24AM A29.00013 Disorder tuned anomalous Hall effect in thin films of Cr doped topological insulators[1] , ZHIYI CHEN, LUKAS ZHAO, INNA KORZHOVSKA, HAIMING DENG, The City College of New York - CUNY, SIMONE RAOUX, JEAN JORDAN, IBM Research - Yorktown, LIA KRUSIN, The City College of New York - CUNY — The anomalous Hall effect (AHE) – an appearance of a voltage transverse to the electric current in the absence of an external magnetic field – is a process that arises from the spin-orbit coupling between current and magnetic moments that has been fundamentally linked to the topological nature of the Hall current. Recent first-principle calculations predict that when topological insulators (TIs) are doped with transition metal ions, such as Cr or Fe, a novel *magnetically ordered* insulating state will form – a state that in thin samples may support a *quantized* anomalous Hall conductance. Here we report an observation of AHE in *rf* sputtered thin Cr doped films of Bi_2Te_3. The anomalous Hall resistivity ρ_{xy} scales with the longitudinal resistivity squared, ρ_{xx}^2, and a distinct ferromagnetic hysteretic response (loops) at temperatures below 10 K with coercive fields of the order of 0.5 T is observed. In as-deposited films the resistivity is below the resistivity quantum h/e^2. Using 2.5 MeV electron beam irradiation with varying fluence we can tune the resistivity upward by orders of magnitude. A large effect of controlled quenched point disorder on the quantization of AHE in Bi_2Te_3 will be discussed.

[1] Supported in part by NSF-DMR-112259

10:36AM A29.00014 Imaging single-atom impurities in topological materials[1] , MICHAEL YEE, ANJAN SOUMYANARAYANAN, YANG HE, Department of Physics, Harvard University, D. GARDNER, Y.S. LEE, Department of Physics, Massachusetts Institute of Technology, Z. SALMAN, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, A. KANIGEL, Department of Physics, Technion - Israel Institute of Technology, Y. ANDO, Institute of Scientific and Industrial Research, Osaka University, J.E. HOFFMAN, Department of Physics, Harvard University — We use low temperature spectroscopic scanning tunneling microscopy to study topological materials in which the surface states are protected by time reversal symmetry. We image the local density of states around a variety of single-atom impurities in the presence of a magnetic field. On a subset of these impurities, we observe broad peaks in the local density of states at energies around the Dirac point. Furthermore, we use Landau level spectroscopy and quasiparticle scattering to discuss the interplay between impurities and the surface states.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A30 DCMP: Colloids: Diffusion and Transport 338 - Kazem Edmond, New York University

8:00AM A30.00001 Long range transport of colloids in aqueous solutions , DANIEL FLOREA, SAMI MUSA, JACQUES M.R.J. HUYGHE, HANS M. WYSS, Eindhoven University of Technology — Colloids in aqueous suspensions can experience strong, extremely long range repulsive forces near interfaces such as biological tissues, gels, ion exchange resins or metals. As a result exclusion zones extending over several millimeters can be formed. While this phenomenon has been previously described, a physical understanding of this process is still lacking. This exclusion zone formation is puzzling because the typical forces acting on colloidal particles are limited to much shorter distances and external fields that could drive the particles are absent. Here we study the exclusion zone formation in detail by following the time and distance-dependent forces acting on the particles. We present a simple model that accounts for our experimental data and directly links the exclusion zone formation to an already known physical transport phenomenon. We show that the effect can be tuned by changing the zeta potential of the particles or by varying the species present in the aqueous solution. We thus provide a direct physical explanation for the intriguing exclusion zone formation and we illustrate how this effect can be exploited in a range of industrial applications.

8:12AM A30.00002 Transport of charged colloidal particles in a nonpolar solvent in response to an electric field , TINA LIN, THOMAS KODGER, DAVID WEITZ, Harvard University — In nonpolar solvents, particle charging is often controlled through the addition of suitable surfactants, which form charge-stabilizing reverse micelles. By combining microfluidics and confocal microscopy, we directly visualize the dynamics of charged colloidal particles in a nonpolar solvent with reverse micelles in response to an external electric field; this enables us to probe the internal electric field as well as the charging properties of the particle solution. We discover some surprising particle behavior: despite a constant applied electric field, particle transport through the fluid is nonlinear and the apparent particle mobility decays in time; subsequently, the charged particles appear to diffuse freely within the bulk solution. We characterize this behavior and find that the charged reverse micelles play a significant role.

8:24AM A30.00003 Revisiting Taylor Dispersion: Differential enhancement of rotational and translational diffusion under oscillatory shear[1] , BRIAN LEAHY, Department of Physics, Cornell University, DESMOND ONG, Cornell University, XIANG CHENG, ITAI COHEN, Department of Physics, Cornell University — The idea of Taylor dispersion - enhancement of translational diffusion under shear - has found applications in fields from pharmacology to chemical engineering. Here, in a combination of experiment and simulations, we study the translational and rotational diffusion of colloidal dimers under triangle-wave oscillatory shear. We find that the rotational diffusion is enhanced, in addition to the enhanced translational diffusion. This "rotational Taylor dispersion" depends strongly on the strain rate (Peclet number), aspect ratio, and the shear strain, in contradistinction to translational Taylor dispersion in a shear flow, which depends only weakly on strain rate and aspect ratio. This separate tunability of translations and orientations promises important applications in mixing and self-assembly of solutions of anisometric colloids. We discuss the corresponding effect on the structure and rheology of denser suspensions of rod-like particles.

8:36AM A30.00004 Hydrodynamic Behavior of Colloidal Nanorods and Characterization of Length Distributions , CARLOS SILVERA BATISTA, CONSTANTINE KHRIPIN, XIAOMIN TU, MING ZHENG, JEFFREY FAGAN, National Institute of Standards and Technology — Single-walled carbon nanotubes (SWCNTs) are 1D, cylindrical, structures of carbon with long persistence lengths and consistent diameters. In this talk, I will discuss the use of doubly sorted SWCNTs (by buoyancy and length), which are effectively colloidal rods, to explore experimentally the effectiveness of theoretical approximations for the hydrodynamic drag of a freely rotating rod. The objective of this work is to establish and validate the use of Analytical Ultracentrifugation (AUC) as a technique to measure the length distribution of rodlike colloidal particles including SWCNT dispersions. This is particularly necessary for applications of nanotube dispersions, as the transport, optical, and thermal properties, as well as the toxicity of SWCNTs have all been demonstrated to depend on the length. Contrary to AFM, the technique most commonly used to measure length distributions, AUC is able to measure the whole population of particles as they exist in liquid phase. I will present measurements and analysis of SWCNT samples with narrow distributions in length, diameter and buoyancy as measured through AUC and compare them against independent measurements conducted with AFM. Using this data, the validity of hydrodynamic theory for this application is verified.

8:48AM A30.00005 Clustering of Attractive Colloids in Flow , MING HAN, Northwestern University, JONATHAN K. WHITMER, University of Wisconsin–Madison, ERIK LUIJTEN, Northwestern University — The behavior of colloidal suspensions under flow is important for numerous applications, including direct-write techniques employing "colloidal ink." Here we investigate the behavior of colloids flowing through narrow channels. When colloidal particles experience sufficiently strong attractive interactions, cluster formation and ultimately gelation may result. We employ computer simulations to investigate how the size and structure of these clusters, as well as their distribution in the flow, is influenced by various experimental variables, including flow velocity, attraction strength, fluid viscosity, and channel diameter. These simulations incorporate explicit hydrodynamics through the multiparticle collision dynamics (MPC) algorithm. Particular attention is paid to the role of channel boundaries and to the dimensionless parameters characterizing the suspension.

9:00AM A30.00006 Measurements of anisotropic Brownian motion of colloidal clusters , JEROME FUNG, THOMAS G. DIMIDUK, Harvard University, Dept. of Physics, REBECCA W. PERRY, Harvard University, School of Engineering and Applied Sciences, VINOTHAN N. MANOHARAN, Harvard University, School of Engineering and Applied Sciences and Dept. of Physics — Nonspherical colloidal particles can exhibit anisotropic Brownian motion characterized by different translational and rotational diffusion constants about different particle axes. We discuss measurements of anisotropic translational and rotational diffusion constants in triangular colloidal clusters made from three micron-sized colloidal spheres. We use digital holographic microscopy (DHM) and electromagnetic scattering solutions to image the three-dimensional Brownian motion of isolated clusters. We track the cluster centers of mass with $\sim$20 nm precision and the cluster orientations with an angular resolution of $\sim$0.1 radians. We also use DHM to measure the diffusion of colloidal spheres bound to the surface of an emulsion droplet and show that the sphere behavior differs significantly from diffusion on planar surfaces at long time scales.

9:12AM A30.00007 Determination of the hydrodynamic friction matrix for various anisotropic particles[1] , DANIELA KRAFT, Center for Soft Matter Research, New York University, USA, RAPHAEL WITTKOWKSI, HARTMUT LÖWEN, Heinrich Heine University Düsseldorf, Germany, DAVID PINE, Center for Soft Matter Research, New York University, USA — The relationship between the shape of a colloidal particle and its Brownian motion can be captured by the hydrodynamic friction matrix. It fully describes the translational and rotational diffusion along the particle's main axes as well as the coupling between rotational and translational diffusion. We observed a wide variety of anisotropic colloidal particles with confocal microscopy and calculated the hydrodynamic friction matrix from the particle trajectories. We find that symmetries in the particle shape are reflected in the entries of the friction matrix. We compare our experimentally obtained results with numerical simulations and theoretical predictions.

9:24AM A30.00008 Enhanced Diffusion in Quasi-Two-Dimensional Suspensions , ADAR SONN, HAIM DIAMANT, YAEL ROICHMAN, School of Chemistry, Tel Aviv University — We study the Brownian motion of quasi-two-dimensional suspensions of micron-sized particles parallel to a single wall. The dynamics of a suspension near a single wall has two characteristics; the self diffusivity is smaller than in unconfined suspensions, and the hydrodynamic interactions between particles decay with inter-particle distance r, as $1/r^3$. We track the motion of silica beads that sediment to the sample floor due to their high density. Screened Coulomb interactions between the bottom glass wall and the heavily charged surface of the beads maintain the beads floating a few hundred nanometers above the wall. We follow the change in the self diffusivity and hydrodynamic interactions as a function of particle area fraction in the sedimented monolayer, ϕ. As expected, the self diffusion decreases as ϕ increases; however, at large ϕ, we observed an increase in self diffusivity. We also observe strongly correlated motion between particles separated by a distance much larger than their distance from the wall. This long-range hydrodynamic coupling has non-trivial dependence on particles' density. Some possible explanations for these observations will be discussed.

9:36AM A30.00009 Vibrational properties of dense colloidal suspensions with short-range interparticle attraction[1] , MARTIN IWANICKI, Department of Physics, Saint Joseph's University, KE CHEN, Institute of Physics, Chinese Academy of Sciences, ARJUN G. YODH, Department of Physics and Astronomy, University of Pennsylvania, PIOTR HABDAS, Department of Physics, Saint Joseph's University — We investigate vibrational properties of dense colloidal suspensions with short-range attractive particle interactions. Preliminary results show that the so-called boson peak in the attractive glass density of states is weaker than in comparable repulsively-interacting disordered suspensions. Interestingly, the position of the peak shifts to higher frequencies with increasing interparticle attraction strength. The participation ratio, which measures the degree of spatial localization, also shifts to higher frequencies with increasing interparticle attraction. Interestingly, characteristics of quasi-localized modes do not seem to depend on the attraction strength between particles. The observations are consistent with studies in hard-sphere colloidal suspensions where the boson peak frequency decreased with increasing volume fraction, and was understood in the jamming framework.

9:48AM A30.00010 Dynamics of Repulsing Charged Particles: a Fluorescence Cross-Correlation Spectroscopy Study[1] , JINGFA YANG, Institute of Chemistry, Chinese Academy of Sciences, China, LIGANG FENG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, ANDEAS BEST, HANS-JURGEN BUTT, KALOIAN KOYNOV, Max-Planck Institute for Polymer Research, INSTITUTE OF CHEMISTRY, CHINESE ACADEMY OF SCIENCES COLLABORATION, MAX-PLANCK INSTITUTE FOR POLYMER RESEARCH COLLABORATION — Electrostatic interaction controls the stability of charged colloidal particles dispensed in an aqueous solution. In our study, we measured the interaction between charged polystyrene particles by fluorescence cross-correlation spectroscopy (FCCS). Negative correlation function was observed for these repulsing particles and a detailed analysis by Brownian dynamics simulation provided a few important factors of the system: the correlation length at which the interaction dominates and the cage effect in the diffusion of the particles.

10:00AM A30.00011 Order Preservation Between Brownian Particles Modeled By Langevin Dynamics[1] , WILLIAM MAULBETSCH, WILLIAM POOLE, JOSEPH BUSH, DEREK STEIN, Brown University — We studied the dynamics of two overdamped Brownian particles in an elongational force gradient following their release from some initial separation. Using a modified one-dimensional Langevin equation, we computed the probability that the particles maintain their order as a function of time. The probability approaches unity when the work required to bring the particles together against the force gradient greatly exceeds the thermal energy, k_BT. The time window within which the particles are most likely to reverse their order is given by the time to diffuse the initial separation. We apply our theoretical model to the dynamics of DNA monomers approaching the vertex of the Taylor cone in an electrospray ionization mass spectrometer. The likelihood of preserving the sequential order is estimated to be 95% when the neighboring monomers of a stretched polymer are cleaved within 10 nm of the vertex. The implications of these results to a DNA sequencing strategy will be discussed.

10:12AM A30.00012 Eliminating cracking during drying , QIU JIN, PENG TAN, Department of Physics, The Chinese University of Hong Kong, Hong Kong, ANDREW B. SCHOFIELD, The School of Physics and Astronomy, University of Edinburgh, Edinburgh, UK, LEI XU, Department of Physics, The Chinese University of Hong Kong, Hong Kong — When colloidal suspensions dry, stresses build up and cracks often occur - a phenomenon undesirable for important industries such as paint and ceramics. We demonstrate that the two viscoelastic moduli, G' and G'', determine the cracking behavior. By adding emulsion droplets into colloidal suspensions, we systematically decrease the storage modulus, G', and increase the importance of the loss modulus, G'', and effectively decrease the amount of cracks. At a critical droplet concentration, cracking disappears completely. Furthermore,adding droplets also varies the speed of air invasion and provides a powerful method to adjust drying rate. With the effective control over cracking and drying rate, our experiment may find important applications in many drying and cracking related industrial processes.

10:24AM A30.00013 Aging in Colloidal Glasses: a comparison between micro and macrorheology[1] , XIAOJUN DI, XIAOGUANG PENG, GREGORY MCKENNA, Texas Tech University, TEXAS TECH UNIVERSITY TEAM — The analogy between colloidal dynamics and the dynamics of molecular glasses remains an important area of study. Of particular interest to our team is the aging responses of the two systems. We have been investigating the dynamics of colloidal systems composed of thermosensitive particles that change diameter upon change of temperature and comparing the behavior to what is expected in molecular glass-formers. In particular, we have found that concentration jumps in these systems mimic three important behaviors of molecular glasses: the intrinsic isotherm, the asymmetry of approach, and memory effect. In our early work, we were able to show, using multispeckle diffusing wave spectroscopy, that although the three signatures are observed in the concentration jump conditions, they are not identical to the observations in molecular glasses. In the present work, in order to get better resolution for the temperature dependent properties, we are employing PNIPAAM/PS particles with core-shell structure to lessen the temperature sensitivity of the system. A series of different particles with different PNIPAAM fractions (different thermal sensitivity) is being investigated and a comparison of the aging between the microrheology and the macrorheology will be made.

10:36AM A30.00014 When Colloids Can Deform , JIE ZHANG, CHANGQIAN YU, SUNG CHUL BAE, STEVE GRANICK, UIUC — Most colloidal systems that have been explored so far are hard-spheres, which limits their phase behavior and other physical properties to be not so rich as atomic and molecular systems. Here we present a new class of soft and deformable microgel colloidal particles with thermo-sensitivity and ability to display autonomous oscillation when driven by special fuels. The deformability, size changes and structure formation of micron-sized poly(NiPAM) particles and dumbbells of polystyrene-poly(NiPAM) interpenetrating networks can be imaged in situ and analyzed. Other mechanical and other physical properties attributable to deformability can be measured.

Monday, March 18, 2013 8:00AM - 10:36AM –

Session A31 DPOLY GERA: Polymer Membranes for Clean Energy and Water I 339 - Xinran Zhang, Georgetown University

8:00AM A31.00001 Conductivity Scaling Relationships for Nanostructured Block Copolymer/Ionic Liquid Membranes , MEGAN HOARFROST, University of Minnesota, RACHEL SEGALMAN, University of California, Berkeley — Nanostructured membranes containing structural and ion-conducting domains are of great interest for a wide range of applications requiring high conductivity coupled with high thermal stability. To optimize the properties of such membranes, it is essential to understand scaling relationships between composition, structure, temperature, and ionic conductivity. The conductivity behaviors of mixtures of two block copolymer chemistries with two different ionic liquids have been investigated. The conductivities of all the mixtures are described by a single expression, which combines the Vogel-Tamman-Fulcher (VTF) equation with percolation theory. The VTF equation takes into account the effect of the glass transition temperature of the conducting phase on the temperature dependence of conductivity, while percolation theory reflects the power law dependence of conductivity on the overall volume fraction of ionic liquid in the membrane. The dominance of the overall volume fraction of ionic liquid in determining conductivity indicates that there is incredible flexibility in designing highly conductive block copolymer/ionic liquid membranes.

8:12AM A31.00002 Ionic Block Copolymers for Anion Exchange Membranes[1] , TSUNG-HAN TSAI, Department of Polymer Science and Engineering, University of Massachusetts-Amherst, DAN HERBST, University of Chicago, GUINEVERE A. GIFFIN, VITO DI NOTO, Department of Chemical Sciences, University of Padova, TOM WITTEN, University of Chicago, E. BRYAN COUGHLIN, Department of Polymer Science and Engineering, University of Massachusetts-Amherst — Anion exchange membrane (AEM) fuel cells have regained interest because it allows the use of non-noble metal catalysts. Until now, most of the studies on AEM were based on random polyelectrolytes. In this work, Poly(vinylbenzyltrimethylammonium bromide)-b- (methylbutylene) ([PVBTMA][Br]-b-PMB) was studied by SAXS, TEM and dielectric spectroscopy to understand the fundamental structure-conductivity relationship of ion transport mechanisms within well-ordered block copolymers. The ionic conductivity and the formation of order structure were dependent on the casting solvent. Higher ion exchange capacity (IEC) of the membranes showed higher conductivity at as IEC values below 1.8mmol/g, as above this, the ionic conductivity decreases due to more water uptake leading to dilution of charge density. The humidity dependence of morphology exhibited the shifting of d-spacing to higher value and the alteration in higher characteristic peak of SAXS plot as the humidity increase from the dry to wet state. This phenomenon can be further explained by a newly developed polymer brush theory. Three ionic conduction pathways with different conduction mechanism within the membranes can be confirmed by broadband electric spectroscopy.

8:24AM A31.00003 Anion Exchange Membranes Based on Reactive Block Copolymers , RICK BEYER, SAMUEL PRICE, AARON JACKSON, XIAOMING REN, DERYN CHU, Army Research Laboratory, YUESHENG YE, YOSSEF ELABD, Drexel University — The unmet needs for polymeric AEMs include high hydroxide conductivity, chemical stability under strongly basic conditions, and sufficient mechanical properties to withstand the temperature and humidity fluctuations in a fuel cell. This presentation will include our most recent findings from an effort to develop cation-containing polymers based on phosphonium and ammonium derivatives of styrene using co-polymerization of reactive, ion-containing block copolymers with a small molecule "matrix" monomer. By creating polymer membranes with co-continuous cation-containing domains in a cross-linked matrix, we hope to demonstrate high conductivity simultaneously with the robust mechanical properties required in the fuel cell environment. Morphological data from SAXS and TEM, mechanical property measurements, in- and through-plane charge transport measurements, and the results of fuel cell testing will be presented. It was found that the surface transport characteristics of these materials differ from the through-plane properties, that chemical crosslinks may not produce membranes with the required toughness, and that a polymerization technique that is highly sensitive to reaction kinetics is not ideal for the production of AEMs.

8:36AM A31.00004 Morphology and Proton Transport in Sulfonated Block Copolymer and Mesoporous Polymer Electrolyte Membranes[1] , CHELSEA CHEN, Materials Sciences Division, Lawrence Berkeley National Laboratory, DAVID WONG, Department of Chemical and Biomolecular Engineering, University of California, Berkeley, KEITH BEERS, Exponent, NITASH BALSARA, Department of Chemical and Biomolecular Engineering, University of California, Berkeley — In an effort to understand the fundamentals of proton transport in polymer electrolyte membranes (PEMs), we have developed a series of poly(styrene-b–ethylene-b–styrene) (SES) membranes. The SES membranes were subsequently sulfonated to yield proton conducting S-SES membranes. We examine the effects of sulfonation level, temperature and thermal history on the morphology of S-SES membranes in both dry and hydrated states. The effects of these parameters on water uptake and proton transport characteristics of the membranes are also examined. Furthermore, building upon the strategy we deployed in sulfonating the SES membranes, we fabricated mesoporous S-SES membranes, with pores lined up with the proton conducting channels. These membranes have three distinct phases: structural block, proton-conducting block, and void. We examine the effects of pore size, domain structure and sulfonation level on water uptake and proton conductivity of the mesoporous PEMs at different temperatures.

[1]This work is funded by Department of Energy.

8:48AM A31.00005 Characterization of Hybrid Polyhedral Oligomeric Silsesquioxane (POSS)-Polybenzimidazole (PBI)-Phosphoric Acid (PA) Materials Intended for Proton Exchange Membranes (PEM) , ROBERT BUBECK, EDMUND STARK, Michigan Molecular Institute, BERRYINNE DECKER, Chemsultants International, CLAIRE HARTMANN-THOMPSON, Michigan Molecular Institute — Isophthalic acid and 3,3'-diaminobenzidine (DAB) were polymerized in the presence of polyphosphoric acid (PPA) and various additives, degree of polymerization was monitored by viscosity and torque change measurements, and membranes were prepared by casting the reaction solution and allowing PPA to hydrolyze to PA under ambient conditions. As a function of relative humidity, the membranes were characterized for (1) acid content, (2) in-plane conductivity and (3) complex shear modulus G* obtained via oscillatory parallel plate dynamic mechanical spectroscopy. The addition of sulfonated octaphenyl polyhedral oligomeric silsesquixane (S-POSS) to m-polybenzimidazole (PBI)-phosphoric acid (PA) membranes resulted in increased in-plane proton conductivity at high temperatures (120-150 °C) and increased G* relative to a m-PBI control membrane and to m-PBI control membranes carrying comparable weight loadings of non-proton conducting octaphenyl-POSS nanoadditive or silica.

9:00AM A31.00006 Molecular Dynamics Simulation of Polysulfone-Based Anion Exchange Membrane Fuel Cell , SEUNG SOON JANG, KYUNG WON HAN, JI IL CHOI, School of Materials Science and Engineering, Georgia Institute of Technology, 771 Ferst Drive NW, Atlanta, GA 30332-0245, COMPUTATIONAL NANOBIO TECHNOLOGY LABORATORY TEAM — In this study, we investigate the nanophase-segregated structures and transport properties of quaternary ammonium grafted polysulfone membranes using molecular dynamics simulation method. For this, we develop a new force field from a reference density functional theory modeling with B3LYP and 6-31G** in order to describe the hydroxide anion. The bond stretching force constant is determined to reproduce the quantum mechanical vibrational frequency. The atomic charges are determined by Mulliken population analysis. Through the annealing procedure, the nanophase-segregated structure is developed as a function of water contents such as 10 and 20 wt %. The extent of nanophase-segregation is evaluated by the structure factor analysis, which can be compared with the experimental small angle scattering data. Once the equilibrium structures are obtained, we run long MD simulations to analyze the diffusion of water and hydroxide using the mean-square displacement analysis with an assumption of Gaussian diffusion. The nanophase-segregated structures and the transport properties will be compared to the proton exchange membrane consisting of the same polymer backbone except for the acidic functional group.

9:12AM A31.00007 Predicting inhomogeneous water absorption in an ionic diblock polymer membrane[1] , DANIEL HERBST, THOMAS WITTEN, University of Chicago Physics Department and James Franck Institute — Fuel cells convert fuel directly into electrical power. Their performance depends on a permeable (yet strong) membrane to allow ion conduction (while preventing combustion). Anion-exchange membrane fuel-cells are especially economical to produce, but technological hurdles currently limit durability and OH^- conductivity of the membrane. One solution to these problems is a diblock morphology. Layers of stiff hydrophobic polymer provide structure, while interspersed layers of polyelectrolyte provide avenues for conduction. Previously, little was known about the structure within the conducting layer. We adapted Scheutjens-Fleer polymer-brush theory to a lamellar geometry. The calculation tells where the polyelectrolytes congregate within a lamella, and hence how conduction occurs. This talk focuses on a new diblock material, PMB-PVBTMA. We show how the features of the material determine the intra-lamellar structure. We conclude that at low humidity, the bulkiness of PVBTMA causes it to adopt a near-uniform distribution within the conducting block. At high humidity, however, a phase separation may induce abrupt water channels. Understanding the architecture within the conducting layer will help guide research into better anion-exchange membranes materials.

[1]The authors would like to thank the Army Research Office for support of this research under the MURI #W911NF-10-1-0520.

9:24AM A31.00008 Swelling of ultrathin crosslinked polyamide water purification membranes , EDWIN CHAN[1], CHRISTOPHER STAFFORD[2], National Institute of Standards and Technology — Polyamide (PA) ultrathin films represent the state-of-the-art nanofiltration and reverse osmosis membranes used in water desalination. The performance of these materials, such as permselectivity, is intimately linked with extent of swelling of the PA network. Thus, quantifying their swelling behavior would be a useful and simple route to understanding the specific network structural parameters that control membrane performance. In this work, we measure the swelling behavior of PA ultrathin films using X-ray reflectivity as a function of water hydration. By applying the Flory-Rehner theory used to describe the swelling behavior of polymer networks, we quantify the PA network properties including Flory interaction parameter and the monomer units between crosslinks. Finally, we demonstrate application of this measurement approach for characterizing the network properties of different types of PA ultrathin films relevant to water purification and discuss the relationship between network and transport properties.

9:36AM A31.00009 Molecular Dynamics Simulations of a Single Chain Pentablock Ionomer in Dilute Solutions[1] , DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — Co-polymers are in the core of many applications such as fuel cells, batteries and purification membranes that require transport across membranes. The challenge remains however that under the condition that transport is optimized, the stability of the membranes is compromised. To surmount this challenge, co-polymers with blocks targeting specific roles have been designed. Using molecular dynamics simulations we have studies the structure and dynamics of ionic single chain pentablock copolymer *(A-B-C-B-A)* containing randomly sulfonated polystyrene in the center, tethered to poly-ethylene-r-propylene end-capped by poly$-t-$butyl styrene. The ionic block facilitates transport while the A and B componenet are incorporated for mechanical stability. The conformation and dynamics of single pentablock ionomer of molecular weight M_w = 50,000g/mol in an implicit poor solvent with dielectric constant of 1 and 77.7, water, and mixture (1:1) of cyclohexane and n-heptane at 300K and 500K will be presented. The effect of solvents on conformation of a single molecule of pentablock was determined and compared with experiment, providing a stepping stone to the understanding phase behavior of this polymer.

[1]This work is partially supported by DOE DE-FG02-12ER46843.

9:48AM A31.00010 Gas Permeation through Polystyrene-Poly(ethylene oxide) Block Copolymers , DANIEL HALLINAN JR., Dept. of Chem. and Biomed. Eng., FAMU/FSU, MATTEO MINELLI, MARCO GIACINTI-BASCHETTI, DICMA, University of Bologna, NITASH BALSARA, Dept. of Chem. Eng,, UC Berkeley — Lithium air batteries are a potential technology for affordable energy storage. They consist of a lithium metal anode and a porous air cathode separated by a solid polymer electrolyte membrane, such as PEO/LiTFSI (PEO = poly(ethylene oxide), LiTFSI = lithium bis-trifluoromethane sulfonimide). For extended operation of such a battery, the polymer electrolyte must conduct lithium ions while blocking electrons and gases present in air. In order to maintain a pressure difference the membrane must be mechanically robust, which can be achieved by incorporating the PEO into a block copolymer with a glassy block such as PS (PS = polystyrene). To protect the lithium electrode, the membrane must have low permeability to gases in air such as CO_2, N_2, and O_2. We have therefore studied the permeation of pure gases through a PS-PEO block copolymer. A high molecular weight, symmetric block copolymer with a lamellar morphology was used to cast free-standing membranes. Gas permeability was measured through these membranes with a standard, pressure-based technique. A model was developed to account for transport through the polymer membrane consisting of semi-crystalline PEO lamellae and amorphous PS lamellae. PEO crystallinity was extracted from the permeation model and compares well with values from differential scanning calorimetry measurements.

10:00AM A31.00011 Nanoporous thin films from nanophase-separated hybrids of block copolymer/metal salt , YOSHIO SAGESHIMA, ATSUSHI NORO, YUSHU MATSUSHITA, Nagoya University — Block copolymers self-assemble into periodic nanostructures, i.e. nanophase-separated structures, which can be scaffolds for nano-applications such as nanoporous membranes, nanolithographic masks, photonic crystals, etc. In this study, we report facile preparation to achieve nanoporous thin films from nanophase-separated hybrids comprising polystyrene-b-poly(4-vinylpyridine) (PS-P4VP, M_n =54k, PDI=1.13, f_s =0.61) and water-soluble iron(III) chloride ($FeCl_3$), where $FeCl_3$ are incorporated into a P4VP phase via metal-to-ligand coordination. To obtain a nanoporous film, firstly a hybrid thin film was prepared by microtoming. Then, the film was immersed into water to remove metal salts, this simple procedure can produce nanoporous thin film. Morphological observations were conducted by using transmission electron microscopy (TEM). Ordered cylindrical nanopores were observed in the thin film of the water-immersed hybrid, which originally presents cylindrical nanodomains. The nanoporous film was modified by loading another metal salt, samarium(III) nitrate, into nanopores via coordination between the metal salt and P4VP tethered to the pore walls. The structure of the sample after modification was evaluated by TEM and an energy dispersive X-ray spectroscopy.

10:12AM A31.00012 Highly-Ordered Thin Films from Photocleavable Block Copolymers[1] , WEIYIN GU, University of Massachusetts at Amherst, HUI ZHAO, University of Hamburg, E. BRYAN COUGHLIN, University of Massachusetts at Amherst, PATRICK THEATO, University of Hamburg, THOMAS RUSSELL, University of Massachusetts at Amherst, UNIVERSITY OF MASSACHUSETTS AT AMHERST TEAM, UNIVERSITY OF HAMBURG TEAM — A robust route for the preparation of nanoscopic dot/line patterns with long range lateral order from poly(styrene-block-ethylene oxide) (PS-b-PEO) with an o-nitrobenzyl ester junction (PS-hν-PEO) is demonstrated. Solvent annealing condition is optimized to achieve the highly ordered cylindrical block copolymer (BCP) microdomains oriented normal or parallel to the silicon substrates. Following a very mild UV exposure and successive washing with methanol, PS-hv-PEO thin films were transformed into highly ordered porous or trench templates. Afterwards the pores or trenches were either filled with PDMS by spin-coating or exposed to direct metal deposition of Au. After a plasma etching or lift-off process to remove the polymer templates, highly ordered arrays of silica or Au nanopatterns were obtained. This represents the first template application example from highly ordered nanoporous thin films derived from block copolymers featuring a photocleavable junction.

10:24AM A31.00013 Understanding the Internal Structure of Layered Organic Compounds deposited on mineral surface using Neutron Reflectivity[1] , HAILE AMBAYE, SNS, ORNL, Oak Ridge, SINDHU JAGADAMMA, LOUKAS PETRIDIS, MELANIE MAYES, Energy and Environmental Sciences Directorate, ORNL, Oak Ridge, VALERIA LAUTER, SNS, ORNL, Oak Ridge — Organic carbon (OC) stabilization in soils plays a significant role in the global C cycle, therefore the understanding of the structure and function of the OC-soil mineral interface is of high importance. To study the internal structure, films with different combination of simple OC compounds, natural organic matter (NOM), Bi-layers of SA (Stearic Acid) on Glucose and NOM/Hydrophilic-NOM/Hydrophobic-NOM were deposited onto sapphire using spin coating. The phobic and phylic fractions of the NOM are operationally separated by exchange resins. We obtained detailed structural depth profile of the films using the depth-sensitive technique of the neutron reflectometry. The neutron reflectivity data were collected at the MAGICS Reflectometer at Spallation Neutron Source at the ORNL. Self-assembled ordering of SA in a repeating bi-layer structure was observed when it was deposited on NOM, phylic-NOM and Glucose. However, when SA was added to phobic-NOM no ordering of SA was detected. The formation of distinct, immiscible layers is due to insolubility of SA with NOM/Hydrophilic-NOM and Glucose. Our results reveal that the OC-mineral interface form complex layering and that the sequence of the layering depends on the compounds.

Session A32 DPOLY: Focus Session: Crystallization and Directed Assembly of Multicomponent Systems 340 - Christopher Li, Drexel University

8:00AM A32.00001 Kinetically Trapped Morphologies in Organic Photovoltaics , THOMAS RUSSELL, University of Massachusetts Amherst — Controlling the morphology in the active layer of organic photovoltaic (OPV) devise is key in optimizing the performance. To this end, bicontinuous morphologies with characteristic length scales of several tens of nanometers of the electron and hole conducting materials, where the order and orientation of both components are optimized to absorb light over the broadest possible range of the visible spectrum and to transport holes and electrons, after exciton dissociation, Yet, these morphologies are trapped in morphologies that are far removed from equilibrium where multiple kinetic processes, including ordering, phase separation, and the segregation of components to interfaces are arrested as solvent, co-solvents and additives are removed during the preparation of the active layer. Time resolved hard x-ray scattering, resonance soft x-ray scattering and high resolution transmission electron microscopy, along with mobility and transport measurements, have been used to understand the parameters that lead to the development of and can be used to control the morphology of the active layers. In addition, by using ternary mixtures of two polymers active in different parts of the solar spectrum along with an electron transporting material, like PCBM, morphologies can be developed to further enhance the efficiency of these devices.

8:36AM A32.00002 ABSTRACT WITHDRAWN –

8:48AM A32.00003 Polythiophene-CdSe Nanorod Assembly Using Electric Field[1] , SIRINYA CHANTARAK, TODD EMRICK, THOMAS P. RUSSELL, University of Massachusetts Amherst — We report controlled solvent evaporation and electric-field assisted vertical alignment of CdSe nanorods (NRs) in a poly(3-hexylthiophene) (P3HT) matrix over large micron areas. NRs of well-defined sizes were synthesized to optimize the geometries of devices made from these nanorods. Regioregular P3HT chains and oligothiophene were functionalized with ligating end-groups to provide contact to the NRs. Hexagonal arrays of these nanocomposites were characterized by transmission electron microscopy (TEM).

9:00AM A32.00004 SANS and SAXS Studies of DNA-Templated Silver Nanoclusters , HONGYU GUO, SUNIL K. SINHA, Department of Physics, UC San Diego, JASWINDER SHARMA, JENNIFER S. MARTINEZ, ANDREW P. SHREVE, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Due to the high affinity of silver cations (Ag+) for DNA bases, following reduction of the Ag+, silver atoms may form short oligonucleotide-encapsulated Ag nanoclusters (<1 nm) without the formation of large particles. Such DNA-templated silver nanoclusters have received significant attention as potential fluorescent labels due to their useful properties, including high molar absorptivities, good quantum yields and photostability, and small size. It is thus of great interest to find out the configuration of the Ag nanoclusters which associate with the DNA strands. We have conducted Small Angle Neutron Scattering (SANS) and X-ray Scattering (SAXS) experiments to investigate the formation of the Nanoclusters. By comparing SANS and SAXS data from conjugated samples, pure DNA and DNA/Ag complex, we can characterize the size and position of the Ag clusters along the DNA strand. The time evolution of the DNA/Ag complex can also be studied and can be understood as due to silver oxidation, reduction, or regrouping. We find that the formation and aging of the Ag Nanoclusters are also strongly dependent on the DNA template sequence.

9:12AM A32.00005 Polymer Crystallization at Curved Liquid-Liquid Interface , CHRISTOPHER LI, WENDA WANG, HAO QI, ZIYIN HUANG, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA 19104, USA — Curved space is incommensurate with typical ordered structures with three-dimensional (3D) translational symmetry. However, upon assembly, soft matter, including colloids, amphiphiles, and block copolymers (BCPs), often forms structures depicting curved surface/interface. Examples include liposomes, colloidosomes, spherical micelles, worm-like micelles, and vesicles (also known as polymersomes). For crystalline BCPs, crystallization oftentimes overwrites curved geometries since the latter is incommensurate with crystalline order. On the other hand, twisted and curved crystals are often observed in crystalline polymers. Various mechanisms have been proposed for these non-flat crystalline morphologies. In this presentation, we will demonstrate that curved liquid/liquid (L/L) interface can guide polymer single crystal growth. The crystal morphology is strongly dependent on the nucleation mechanism. A myriad of controlled curved single crystals can be readily obtained.

9:24AM A32.00006 Dynamic Temperature Gradient Effects on Directed Self Assembly of Thin Films of Block Copolymer/Au Nanoparticle Multicomponent Systems , REN ZHANG, GURPREET SINGH, University of Akron, ALEI DANG, MICHAEL BOCKSTALLER, Carnegie Mellon University, ALAMGIR KARIM, University of Akron — The influence of temperature and Au nanoparticle (NP) concentration on the morphology and properties of poly(styrene-b-methylmethacrylate) (PS-PMMA) block copolymer (BCP) thin films (thickness 80100nm) were investigated. The Au core was grafted with thiol-terminated polystyrene to ensure the preferential interaction to the PS domains. The concentration of Au NPs was varied between 0-10% with respect to PS-PMMA by weight. To induce microphase separation, both static oven annealing and a dynamic thermal field termed cold zone annealing (CZA) were performed. At low temperature annealing ($< 150^{\circ}$C), horizontal cylindrical morphologies were observed, while at high temperature annealing (150-210°C), an orientation transition of cylindrical microdomains from vertical to horizontal were observed with increasing Au NPs concentration coupled with an increase in reflective index. The morphology transition is attributed to the decreased thermal conductivity caused by the increasing heterogeneity and growing number of scattering centers. Additionally, we demonstrate unidirectional alignment of BCP/Au NP domains by a novel modification of the CZA method. The dispersion of Au NPs was investigated via TEM and AFM.

9:36AM A32.00007 A Study on the Packing and Phase Separation of Dissimilar Nanoparticles , XIAOBO SHEN, Department of Polymer Science and Engineering, University of Massachusetts-Amherst, DONG WANG, WPI-Advanced Institute for Materials Research (WPI-AIMR), Tohoku University, DHANDAPANI VENKATARAMAN, Department of Chemistry, University of Massachusetts-Amherst, TADAFUMI ADSCHIRI, KEN NAKAJIMA, WPI-Advanced Institute for Materials Research (WPI-AIMR), Tohoku University, THOMAS RUSSELL, Department of Polymer Science and Engineering, University of Massachusetts-Amherst — To develop a novel approach for the preparation of organic photovoltaic active layer using binary functional nanoparticle assemblies, the nature and characteristics of the interactions and packing between dissimilar nanoparticles must be understood. Here, polymer-based, namely polystyrene (PS), and inorganic-based, namely zinc oxide (ZnO) and titanium oxide (TiO2), nanoparticles are prepared by miniemulsion and hydrothermal reaction methods, respectively. Different functionalities on the particle surface are imparted by further functionalization. The binary assembly of the dissimilar particles is carried out in a variety of ways including solution mixing, non-solvent precipitation, thermal- and solvent annealing, etc. and characterized by Force Volume-AFM (FV-AFM), SEM, TEM and GISAXS techniques. The resulting packing and segregation of the dissimilar particles are shown to be effectively dependent on the molecular weight, inter-particle interactions, particle aspect ratios and sizes, etc.

9:48AM A32.00008 Self-Assembly of Giant Molecular Shape Amphiphiles based on Polystyrene Tethered Hydrophilic POSS/C_{60} Nanoparticles , XINFEI YU, I-FAN HSIEH, KAN YUE, WEN-BIN ZHANG, STEPHEN CHENG, The University of Akron — Giant molecular shape amphiphiles (GMSAs) are molecules with two blocks which have different chemical properties and shapes. These molecules are precisely synthesized by controlled/living polymerization and "click" chemistry. Self-assembly behaviors of GMSAs are explored in solution, bulk, and thin film states. Micelles (spheres, cylinders, and vesicles) are obtained in the solutions, which are controlled by molecular topology, polymer length, and solvent properties. Nanophase separated structures at 10 nm scale are obtained in the bulk state, which are dependent on volume fractions of each block as well as molecular topology. The nanophase separated structures of GMSAs in the bulk state imply their potential applications in thin-film nano-patterning. Compared with traditional block copolymers, the shape-persistent feature of the molecular nanoparticles might help to reduce the line-edge roughness. Shape and interactions are conclude as two important factors to determine the self-assembly of these molecules.

10:00AM A32.00009 Self-assembly of ABA amphiphilic block copolymers and its metastable behavior , WEI JIANG, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — Amphiphilic triblock copolymer can self-assemble into a vast variety of micelles in selective solvents. We investigated, both theoretically and experimentally, the kinetics of the vesicle formation of ABA amphiphilic triblock copolymers in a selective solvent by cooling the system from an initially homogeneous state at different rates. It was found that the pathway of spontaneous vesicle formation depended on the cooling rate. This road path difference for vesicle formation can be attributed to the existence of many metastable states in the system. Moreover, it was found that in uniform shear flow, the size distribution of the vesicles was much narrower than that in nonuniform shear flow and the uniformity of the vesicles increased with increasing shear rate. The results show that the metastable states in the system can be modulated and the morphological polydispersity of amphiphilic ABA triblock copolymer vesicles can be controlled by shear flow.

10:12AM A32.00010 ABSTRACT WITHDRAWN –

10:24AM A32.00011 Phase Separation in a Dynamically Asymmetric Polymer Blend: a Stepwise Growth Mechanism , CHARLES HAN, Institute of chemistry, chinese Academy of Sciences, ICCAS, WEICHAO SHI, ICCAS — Phase separation dynamics of a polymer blend can be mediated under competition between thermodynamic perturbation and asymmetric viscoelasticity due the contrast in the glass transition temperatures of the two polymer components. The viscous fluidic and soft elastic properties will meet in the phase separation dynamics in this study. Between the two cases, we further revealed a stepwise concentration growth phenomenon, which consists of two individual growths and a "frozen" period in between. This stepwise growth should be a general mechanism for asymmetric polymer blends.

10:36AM A32.00012 Rigid Amorphous Fraction in PLA Electrospun Fibers[1] , PEGGY CEBE, QIAN MA, Tufts University, ERIKA SIMONA COZZA, University of Genoa, MAREK PYDA, BIN MAO, YAZHE ZHU, Tufts University, ORIETTA MONTICELLI, University of Genoa — Electrospun fibers of poly(lactic acid) (PLA) were formed by adopting a high-speed rotating wheel as the counter-electrode. The molecular orientation, crystallization mechanism, and phase structure and transitions of the aligned ES fibers were investigated. Using thermal analysis and wide angle X-ray scattering (WAXS), we evaluated the confinement that exists in as-spun amorphous, and heat-treated semicrystalline, fibers. Differential scanning calorimetry confirmed the existence of a constrained amorphous phase in as-spun aligned fibers, without the presence of crystals or fillers to serve as fixed physical constraints. Using WAXS, for the first time the mesophase fraction, consisting of oriented amorphous PLA chains, was quantitatively characterized in nanofibers.

10:48AM A32.00013 Diameter-Dependent Modulus and Melting Behavior in Electrospun Semicrystalline Polymer Fibers[1] , YING LIU, SHUANG CHEN, Department of Material Science and Engineering, Stony Brook University, EYAL ZUSSMAN, Department of Mechanical Engineering, Technion-Israel Institute of Technology, CHAD KORACH, WEI ZHAO, Department of Mechanical Engineering, Stony Brook University, YICHEN GUO, MIRIAM RAFAILOVICH, Department of Material Science and Engineering, Stony Brook University — Confinement of the semicrystalline polymers, poly-(ethylene-co-vinyl acetate) (PEVA) and low-density polyethylene (LDPE), produced by electrospinning has been observed to produce fibers with large protrusions, which have not been previously observed in fibers of comparable diameters produced by other methods. SAXS spectra confirmed the crystalline structure and determined that the lamellar spacing was almost unchanged from the bulk. Measurement of the mechanical properties of these fibers, by both shear modulation force microscopy (SMFM) and atomic force acoustic microscopy (AFAM), indicates that the modulii of these fibers increases with decreasing diameter, with the onset at $\sim$10 μm, which is an order of magnitude larger than previously reported. Melting point measurements indicate a decrease of more than 7% in T_m/T_0 (where Tm is the melting point of semicrystalline polymer fibers and T_0 is the melting point of the bulk polymer) for fibers ranging from 4 to 10 μm in diameter. The functional form of the decrease followed a universal curve for PEVA, when scaled with T_0.

Session A33 DPOLY DMP: Focus Session: Dielectric and Ferroelectric Polymers for Electrical Applications: Dielectrics 341 - Lei Zhu, Case Western Reserve University

8:00AM A33.00001 Imaging the Effect of Electrical Breakdown in Multilayer Polymer Capacitor Films[1] , MASON WOLAK, US Naval Research Lab — Multilayer polymer films show great promise as the dielectric material in high energy density capacitors. Such films show enhancement in both dielectric strength (E_B) and energy density (U_d) relative to monolithic films of either source polymer. Composites are typically comprised of alternating layers of a high E_B polymer and a high permittivity polymer. Here, we discuss a multilayer system based on polycarbonate (PC) interleaved with polyvinylidene fluoride-hexafluoropropylene (PVDF-HFP). The dielectric properties of the PC/PVDF-HFP films are influenced by both composition and individual layer thickness. Optimized films show E_B =750 kV/mm and U_d =13 J/cm^3. Further enhancements in E_B and U_d are expected through optimization of the component polymers, composition, and layer structure. To guide next generation design, it is important to understand the breakdown mechanism, as it directly influences E_B. To elucidate the role of the layer structure during electrical breakdown, we use a tandem focused ion beam (FIB) / scanning electron microscope (SEM) imaging technique. The technique allows us to image the internal layer structure of both 'as fabricated' control films, and those subjected to high electric fields. It is therefore a powerful tool to assess film quality and analyze failure mechanisms. Specifically, the FIB is used to mill site-specific holes in a film and the resulting cross-sections are imaged via SEM. Individual layers are easily resolved down to 50 nm. For films subjected to electrical breakdown, the location and propagation of damage is tracked with sequential FIB milling and SEM imaging. Spatially resolved FIB/SEM imaging allows preparation of quasi-3D maps displaying the evolution of internal voids in areas adjacent to the breakdown location (pinhole of d = 30-80 microns). A majority of the voids are localized at the interfaces between layers and may propagate as far as 30-50 microns from the pinhole. The data suggest that the enhancement in dielectric strength arises from a barrier effect, whereby the propagation of an electrical breakdown in the direction of the applied field is impeded by the layer interfaces. We will also discuss recent TEM imaging results that are used to characterize the interfacial length scale and chemical makeup, factors that may influence breakdown.

8:36AM A33.00002 Accelerating Dielectrics Design Using Thinking Machines[1] , R. RAMPRASAD, University of Connecticut — High energy density capacitors are required for several pulsed power and energy storage applications, including food preservation, nuclear test simulations, electric propulsion of ships and hybrid electric vehicles. The maximum electrostatic energy that can be stored in a capacitor dielectric is proportional to its dielectric constant and the square of its breakdown field. The current standard material for capacitive energy storage is polypropylene which has a large breakdown field but low dielectric constant. We are involved in a search for new classes of polymers superior to polypropylene using first principles computations combined with statistical and machine learning methods. Essential to this search are schemes to efficiently compute the dielectric constant of polymers and the intrinsic dielectric breakdown field, as well as methods to determine the stable structures of new classes of polymers and strategies to efficiently navigate through the polymer chemical space offered by the periodic table. These methodologies have been combined with statistical learning paradigms in order to make property predictions rapidly, and promising classes of polymeric systems for energy storage applications have been identified.

9:12AM A33.00003 Dielectric Properties of Poly(carbonate) Containing Oxide Nanoparticles , STEVE GREENBAUM, Hunter College of CUNY, JOHN FONTANELLA, JJFontanella LLC, Annapolis, MD, JOHN BENDLER, BSC, Inc., Rapid City, SD, CHARLES EDMONDSON, MARY WINTERSGILL, U.S. Naval Academy, DAVID BOYLES, TSVETANKA FILIPOVA, South Dakota School of Mines and Technology, MARK WESTGATE, U.S. Naval Academy, ARMANDO RUA, XAVIER BOGLE, Hunter College of CUNY — Nanocomposite of poly(carbonate) (PC) and nanoscopic $BaTiO_3$ have been studied. The complex relative permittivity, $\varepsilon^* = \varepsilon' - j\varepsilon''$, at audio frequencies from 5K to about 500K and the room temperature breakdown strength have been determined. In addition, SEM, DSC and TGA studies have been carried out as well as variable temperature and pressure proton NMR relaxation measurements. ε' is 11 for PC containing 59 wt% of 50-70 nm diameter $BaTiO_3$ and ε' vs. nanoparticle content for the untreated nanoparticles is larger than would be expected on the basis of a recently proposed modified Hanai equation. In addition, the breakdown strength is low and decreases as nanoparticle content increases. Higher breakdown strength is observed when using surface treated nanoparticles. The gamma relaxation (200K and 1000 Hz) does not change as nanoparticle content increases to 59 wt-%. Also, a low temperature relaxation region (in the vicinity of 20K) is found in the heat-treated nanocomposites, which is associated with the nanoparticles themselves. Next, the breakdown strength increases as $BaTiO_3$ nanoparticle size increases from 50 nm to 500 nm. Finally, data for PC containing $SrTiO_3$, $BaZrO_3$, ZrO_2, TiO_2 or SiO_2 may be presented.

9:24AM A33.00004 Theoretical considerations in the design of polymer dielectrics[1] , PHILIP TAYLOR, GAVIN BROWN, JIAYUAN MIAO, ELSHAD ALLAHYAROV, Case Western Reserve University — An ideal dielectric is one that reversibly stores a large amount of energy when exposed to a modest electric field. We have used theory and molecular dynamics simulation as an aid to the development of polymeric materials with favorable properties for energy storage with low dielectric losses. Because the stored energy in a capacitor resides mostly in the energy of distortion of the molecular bonds within the material, it is necessary to optimize the size of the deformable polar units. We achieve this by modeling some of the copolymers of polyvinylidene fluoride, and identifying the preferred density and nature of the cross-linking that pins certain regions of the polymer chains to prevent their rotation when exposed to fields. We then relate this to the electrostatic interactions within chains and between chains in order to take account of the depolarizing fields. We find the optimal length of chain between pinning points to be a function of the applied field strength, and to vary from about ten monomer units at the highest of fields to over a hundred monomers at very weak fields.

9:36AM A33.00005 Properties of Poly(carbonate) Containing Oxide Nanoparticles[1] , JOSEPH LOMAX, Chemistry Department, U.S. Naval Academy, JOHN BENDLER, BSC, Inc, JOHN FONTANELLA, CHARLES EDMONDSON, MARY WINTERSGILL, MARK WESTGATE, Physics Department, U.S. Naval Academy — Nanocomposites composed of poly(carbonate) (PC) and oxide nanoparticles have been studied. For $BaTiO_3$ both as-received and surface-treated (3-aminopropyl-trimethoxysilane) nanoparticles were utilized. The complex relative permittivity, $\varepsilon^* = \varepsilon' - j\varepsilon''$, at audio frequencies from 5K to about 500K and the room temperature breakdown strength have been determined. Also, SEM, DSC and TGA studies have been carried out. ε' is 11 for PC containing 59 wt-% of untreated 50-70 nm diameter $BaTiO_3$ and ε' vs. nanoparticle content is larger than would be expected on the basis of the modified Hanai equation. Also, the breakdown strength is low and decreases as nanoparticle content increases. However, ε' is low and the breakdown strength is high for PC containing the surface-treated nanoparticles. The gamma relaxation (200K and 1000 Hz) does not change as nanoparticle content increases to 59 wt-%. Also, a low temperature relaxation region (in the vicinity of 20K) associated with the nanoparticles is found in the nanocomposites. Next, the breakdown strength increases as $BaTiO_3$ nanoparticle size increases from 50 nm to 500 nm.

9:48AM A33.00006 Morphology of candidate high dielectric constant polymers[1] , DANIEL W. SINKOVITS, MANISH AGARWAL, MAYANK MISRA, SANAT KUMAR, Columbia University — We perform all-atom molecular dynamics simulations of polymers which have been identified as promising candidates for high dielectric constant capacitor applications by single-chain density functional theory calculations. These include both organic polymers and those with SnF_2 substitutions. We determine the large-scale morphology of these polymers using both NPT molecular dynamics simulations and a multistep thermodynamic integration technique.

[1]Multidisciplinary University Research Initiative (MURI)

10:00AM A33.00007 Aromatic Polythiourea Dielectrics with High Energy Density, High Breakdown Strength, and Low Dielectric Loss , SHAN WU, QUINN BURLINGAME, MINREN LIN, QIMING ZHANG, The Pennsylvania State University — There is an increasing demand on dielectric materials with high electric energy density and low loss for a broad range of applications in modern electronics and electrical power systems such as hybrid electric vehicles (HEV), medical defibrillators, filters, and switched-mode power supplies. One major challenge in developing dielectric polymers is how to achieve high energy density U_e while maintaining low dielectric loss, even at very high-applied electric fields. Here we show that amorphous polar-polymers with very low impurity concentration can be promising for realizing such a dielectric polymer. Polar-polymer with high dipole moment and weak dipole coupling can provide relatively high dielectric constant for high U_e, eliminate polarization and conduction losses due to weak dipolar coupling and strong polar-scattering to charge carriers. Indeed, an aromatic polythiourea thin film can maintain low loss to high fields ($>$1 GV/m) with a high U_e ($\sim$ 24 J/cm^3), which is very attractive for energy storage capacitors.

10:12AM A33.00008 Exploration of the Chemical Space of Group 4 Polymer Dielectrics , CHENCHEN WANG, GHANSHYAM PILANIA, RAMPI RAMPRASAD, University of Connecticut — The current standards for capacitive energy storage applications are polypropylene (PP) and polyethylene (PE) which have large band gap and high breakdown strength, but a small dielectric constant. The envisaged next generation dielectric should provide high dielectric constant, while still preserving the insulating characteristics of PP and PE. To meet these growing needs, we use high throughput density functional theory (DFT) calculations in combination with machine learning (ML) methods to identify classes of polymers with large dielectric constant and band gap. In our work, we consider various possible local chemical modifications to polyethylene (PE). To be specific, we allow the -CH_2- unit in the PE backbone segment to be replaced by -SiF_2-, -$SiCl_2$-, -GeF_2-, -$GeCl_2$-, -SnF_2-, or -$SnCl_2$- units in a systematic manner. High throughput methods were used first to accurately determine the dielectric constant and band gap of the chemically modified PE chains for a set of limited compositions and configurations. ML methods were then used to predict the properties of systems spanning a much larger part of the configurational and compositional space. A set of most promising PE modifications (with simultaneously large dielectric constant and band gap) is identified using this strategy.

10:24AM A33.00009 General methodology for creating improved polymeric dielectrics[1] , MAYANK MISRA, MANISH AGARWAL, DANIEL SINKOVITS, SANAT KUMAR, Columbia University — We use molecular dynamics and density functional theory to show that the addition of a small number of polar -OH groups to an apolar, hydrocarbon polymer increases the dielectric constant by a factor of 2, but without substantially increasing the dielectric loss. While these results, which are in good agreement with experiments, point to a specific route to creating improved capacitors, more generally, these results suggest that improved polymeric based dielectric materials can be designed by incorporating polar groups on the chain, but only those whose relaxations can be substantially slowed due to cooperative effects, e.g., through long-lived hydrogen bonds.

10:36AM A33.00010 Large, Uni-directional Actuation In Dielectric Elastomers Achieved By Fiber Stiffening[1] , JIANGSHUI HUANG, DAVID CLARKE, ZHIGANG SUO, Harvard University — Cylindrical actuators are made with dielectric elastomer sheets stiffened with fibers in the hoop direction. When a voltage is applied through the thickness of the sheets, large actuation strains are achievable in the axial direction, with or without pre-straining and mechanical loading. For example, actuation strains of 35.8% for a cylinder with a prestrain of 40%, and 28.6% for a cylinder without pre-strain have been achieved without any optimization. Furthermore, the actuation strain is independent of the aspect ratio of the cylinder, so that both large strains and large displacements are readily actuated by using long cylinders.

[1]Large, Uni-Directional Actuation In Dielectric Elastomers Achieved By Fiber Stiffening

10:48AM A33.00011 Dielectric Performance of Matrix Free, Hairy Nanoparticle Films[1] , CHRISTOPHER GRABOWSKI, ELIZABETH OPSITNICK, HILMAR KOERNER, MICHAEL DURSTOCK, RICHARD VAIA, Air Force Research Laboratory — Addressing the increasing electrical energy storage and power delivery needs of industry has driven development of novel insulating materials. The voltage breakdown characteristics of two-component polymer nanocomposites (PNCs) – nanoparticles dispersed in a polymer matrix – have been previously explored. Control of morphology and dispersion is challenging, however, due to aggregation at high inorganic fractions ($>$ 5% v/v). To fully establish the potential of these nanostructure hybrid materials, we examine the dielectric performance of matrix free, hairy nanoparticle films. These single-component PNCs are comprised of silica nanoparticles with a polystyrene corona such that coronas of adjacent nanoparticles interpenetrate and entangle. Grafting the polymer directly to the nanoparticle provides certain benefits, including more uniform/predictable film morphologies and higher achievable nanoparticle loading. Energy storage capabilities will be assessed from dielectric experimental methods, which include measuring the characteristic dielectric film strength and dielectric permittivity for varying volume fractions of silica.

Session A34 DPOLY: Focus Session: Dynamics of Glassy Polymers Under Nanoscale Confinement: Glass Transition 342 - Robert Riggleman, University of Pennsylvania

8:00AM A34.00001 Calorimetry of Polymer Nanoparticles , RODNEY PRIESTLEY, Princeton University — Significant understanding regarding the dynamics of glassy polymers geometrically confined to the nanoscale has been obtained by investigating thin films. While thin films are an attractive model system to investigate the influence of confinement on material properties, measurements on other geometries is important from both scientific and technological viewpoints. Investigating glassy dynamics of polymer nanoparticles is useful for exploring the influence of geometry on the behavior of confined polymer, and thus, to gain insight into the generality of size-effects on material properties irrespective of the confining shape. Here, we use calorimetry to measure the glassy dynamics (e.g., glass transition temperature, fragility and structural relaxation) of polymers confined to the nanosphere geometry. We illustrate how nanoscale confinement can significantly alter the glassy dynamics of polymer nanoparticles. Our results suggest that interfaces are a key factor in modifying the glassy dynamics of confined polymer, irrespective of geometry.

8:36AM A34.00002 Viscoelasticity of Ultra Thin Films Probed via Temperature-Controlled Quartz Crystal Microbalance With Dissipation[1] , JODIE LUTKENHAUS, JOE PUHR, AJAY VIDYASAGAR, Texas A&M Unversity, LUTKENHAUS LABORATORY TEAM — Temperature-controlled quartz crystal microbalance with dissipation (QCM-D) is a powerful technique for probing glass transitions in ultra thin films via changes in viscoelasticity. QCM-D has the added benefit of monitoring such changes as a function of overtone, which allows for one to probe transitions at different locations vertically throughout the film. Here, we present a general approach towards discerning glass transitions in layer-by-layer (LbL) assemblies, which are formed via the alternate adsorption of oppositely charged polyelectrolytes. LbL assemblies consisting of strong polyelectrolytes or of weak polyelectrolytes are presented. A glass transition was only observed in the presence of water, which extensively plasticized the film and facilitates the breaking and reformation of ion pairs. Early results of glass transitions in homopolymers such as polystyrene are also presented. A strong dependence of glass transition temperature on overtone number was observed, suggesting a range of changes in viscoelasticity with respect to temperature and distance from the substrate.

8:48AM A34.00003 Making the Tg-Confinement Effect Disappear in Thin Polystyrene Films: Good Physics vs. Inappropriate Analysis , JOHN TORKELSON, LAWRENCE CHEN, Northwestern University — The Tg-confinement effect in polymers was first characterized in supported polystyrene (PS) films by Keddie et al. in 1994. Since then, many researchers have shown that (pseudo-)thermodynamic Tg measurements of supported PS films taken on cooling consistently yield the same qualitative results, with a decrease from bulk Tg beginning at 40-60 nm thickness and becoming very strong below 20 nm thickness. Some quantitative differences have been noted between studies, which may be ascribed to measurement method or the analysis employed. In 2004, we showed that the Tg-confinement effect in PS may be suppressed by adding several wt% of small-molecule diluents such as dioctyl phthalate. Recently, Kremer and co-workers (Macromolecules 2010, 43, 9937) reported that there was no Tg-confinement in supported PS films based on an analysis of the second derivative of ellipsometry data and use of a ninth order polynomial fit. Here, we demonstrate a new method for suppressing the Tg-confinement effect. In particular, PS made by emulsion polymerization yields no Tg-confinement effect as measured by ellipsometry or fluorescence, while PS made by anionic or conventional free radical polymerization yield strong Tg-confinement effects. The difference is hypothesized to result from surfactant in the emulsion polymerized PS. We also show that the absence of the Tg-confinement effect reported by Kremer is due to inappropriate analysis of ellipsometry data and that correct analysis yields Tg-confinement effects.

9:00AM A34.00004 Reduced Calorimetric Tg in Confined Thin Polymer Films with Controlled Interface , GI XUE, JIAO CHEN, DONGSHAN ZHOU, Department of Polymer Science and Engineering, Nanjing University — When most prior studies on thin polymer film have shown that glass transition temperature (Tg) decreases under nano-confinement, differential alternating current (AC) chip calorimetric method shows little dependence of Tg on thickness for supported film. To reveal this contradiction, we have manipulated a free-interface by spin-coating polystyrene with an immiscible surfactant [tetraoctylammonium bromide (TOAB)], which had a melting point lower than Tg of polystyrene. When the sample was heated during AC chip measurement, TOAB molecules assembled on the interface and became a mobile layer. As a result, Tg was reduced for ultra thin polymer film. Moreover, stacked free-standing polymer films also show Tg dependence on thickness. The releasing of interface stresses caused by spin-coating is the major reason for reduction of calorimetric Tg. These data unambiguously show that thickness dependence of Tg is an intrinsic property of thin polymer film confined by geometry and dimensions.

9:12AM A34.00005 The Calorimetric Glass Transition of Polystyrene Ultrathin Films , SIYANG GAO, YUNG P. KOH, SINDEE S. SIMON, Texas Tech University, TEXAS TECH UNIVERSITY TEAM — The glass transition temperature (Tg) for nanoconfined materials have been widely studied since the early 1990s. For supported polystyrene ultrathin films, Tg differs from bulk value. Recent work has attributed nanoconstrained Tg effects to artifact. In this study, we attempted to resolve this controversy and measure Tg for single polystyrene ultrathin films using Flash DSC. Films have been prepared in two ways: spincast films placed on a layer of inert oil or grease and films directly spincast on the back of the calorimetric chip. For the films on oil or on grease, the 160 nm thick films show no Tg depression. On the other hand, thinner films on oil and on grease show a Tg depression which decreases with increasing cooling rate. The depression reverts to the bulk values over the course of a day at 160 $^{\circ}$C due to dewetting and thickening. For directly spincast films, no Tg depression is observed, consistent with results from other nanocalorimetry work. Our results are consistent with literature results that Tg decreases with decreasing substrate surface energy, and they also demonstrate that the Tg depression observed is not due to degradation or to plasticization effects.

9:24AM A34.00006 Local Variation of Fragility and Glass Transition Temperature of Ultra-thin Supported Polymer Films , PAUL HANAKATA, Department of Physics, Wesleyan University, Middletown, CT 06459, USA, JACK DOUGLAS, Polymers Division, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, FRANCIS STARR, Department of Physics, Wesleyan University, Middletown, CT 06459, USA — Extensive studies have shown that the properties of ultra-thin polymer films can differ significantly from the bulk. The effect of the film thickness h on the glass transition temperature has been widely examined, but this does not account for the fragility of glass-formation, which quantifies how rapidly relaxation time varies with temperature T. Accordingly, we simulate polymer films of a bead-spring model on a smooth or rough surface and determine both T_g and fragility, both as function of h and film depth. We find that the commonly invoked free-volume layer model does not describe our results. In addition, as opposed to the bulk, we find that T_g and fragility do not generally vary proportionally. Therefore, determination of fragility is essential for the characterization of dynamic changes in film. Finally, we relate these changes of fragility to changes in the cooperative monomer dynamics.

9:36AM A34.00007 Fragility of an Isochorically Confined Polymer Glass , CHUAN ZHANG, YUNLONG GUO, RODNEY PRIESTLEY, Princeton University — When polymers are confined to the nanometer length-scale, the glass transition temperature (T_g) and its associated dynamics can deviate substantially from the bulk. As confined polymers continue to play an important role as enabling materials in technologies ranging from drug delivery to plastic electronics, a greater understanding of size effects on glass transition dynamics is warranted. Here, we present the effect of isochoric confinement on the dynamic fragility of a polymeric glass-former, $i.e.$, polystyrene (PS). Utilizing silica-capped PS nanospheres as a model system, the fictive temperature (T_f) and the isochoric heat capacity (C_v) are measured as a function of diameter *via* differential scanning calorimetry (DSC). By examining T_f as a function of cooling rate for each sample, the isochoric fragility (m_v) is obtained, which decreases significantly as the diameter of the nanospheres is reduced from 462 nm to 129 nm. Hence, the contribution of thermal effects on structural relaxation is reduced with isochoric confinement for PS geometrically restricted by silica. Furthermore, we explore the impact of chemical structure, *via* PS derivatives, on the observed confinement effect on the dynamic fragility.

9:48AM A34.00008 Effects of aging on glass-forming polymers , AMIT SHAVIT, ROBERT RIGGLEMAN, University of Pennsylvania — Despite nearly twenty years of active research, the effects of nanoscale confinement on the properties of glass forming polymers remain poorly understood. Furthermore, molecular simulations have so far only played a limited role in our understanding of these confinement effects, which are important for applications in both membrane separation and semiconductor manufacturing. We have used molecular dynamics simulations to investigate the effects of aging on bulk and free-standing thin-film glass-forming polymers. We demonstrate that in the vicinity of the bulk glass transition temperature, there are regimes where the free surface is in equilibrium while the center of the film exhibits bulk-like aging. We compare our results with those published from recent experiments, and we provide a microscopic picture on the differences in physical aging in bulk and free-standing polymer films.

10:00AM A34.00009 Physical Aging of Thin Polystyrene Films Quenched and Measured Free-Standing , JUSTIN PYE, CONNIE ROTH, Dept of Physics, Emory University — High molecular weight (MW) free-standing polymer films exhibit unusual and yet unexplained nanoconfinement effects. We have recently demonstrated that such ultrathin, high MW free-standing polystyrene (PS) films show two reduced glass transition temperatures (Tgs) which can be separated by more than 60 K, indicating that two separate mechanisms act simultaneously to propagate enhanced mobility into the film from the free surface. These studies indicate that the majority of the film transitions to a glass at the upper Tg leaving only a small fraction of the material mobile to much lower temperatures. In an effort to gain insight into the properties of these films between the two reduced Tgs, we aim to measure the physical aging characteristics at temperatures both above and below the lower transition temperature. To this end, we have developed a method using ellipsometry to measure the physical aging rate of thin free-standing PS films that remain free-standing after being thermally quenched. Measurements on thicker free-standing films, greater than 500 nm, supported by rigid, circular sample holders show no thickness dependence to the aging rate, consistent with the thickness independent stress applied to these films by the thermal expansion mismatch between film and holder. Measurements on thinner films will also be presented.

10:12AM A34.00010 Glass transition temperatures in nanoscale equilibrated polystyrene droplets , CHAD DALEY, JAMES FORREST, University of Waterloo — Measurements of thin film glass transition temperature (Tg) in thin polymer films are only made possible through the metastability of the film with respect to dewetting. Even in the melt state, such samples are not in thermal equilibrium, and resulting Tg values may not be conclusive. In this talk we discuss recent measurements of Tg for equilibrium polystyrene droplets on silicon substrates as measured through their thermal expansion with true non-contact atomic force microscopy. These measurements show promise to not only definitively address the continuing controversy surrounding thin film Tg measurements, but are also readily applied to study non-polymeric glass formers.

10:24AM A34.00011 Confinement effects on the glass transition of nanolayered polymers , DAVID SIMMONS, University of Akron Department of Polymer Engineering, RYAN LANG, MARK MACKURA, The University of Akron Department of Polymer Engineering — Despite numerous studies of glass transition confinement effects in liquids confined in freestanding films, on rigid substrates, and in pores, many outstanding questions remain regarding the origin, nature, and magnitude of these effects. In recent years, studies have demonstrated that these effects are also present in materials under soft confinement, including in internally nanostructured polymers such as nanolayered polymers and block copolymers. This latter class of materials offers a new platform for exploration of confinement effects in the absence of issues surrounding substrate selection and preparation. In this talk, we describe the results of coarse-grained molecular dynamics simulations probing the glass-formation behavior of nanolayered polymers, with a focus on the role of 'cooperatively rearranging regions' in nanoconfinement effects in these systems. Furthermore, we discuss the role of miscibility and bulk T_g of the nanolayered polymers in determining the magnitude and direction of changes to T_g and mobility of polymers under this form of 'soft' nanoconfinement.

10:36AM A34.00012 Dynamic Cluster Size Effects on the Glass Transition of Thin Films , RICHARD WOOL, University of Delaware — During cooling from the melt of amorphous materials, it has been shown experimentally that dynamic rigid clusters form in equilibrium with the liquid and their relaxation behavior determines the kinetic nature of T_g [Stanzione et al, J. Non Cryst Solids 357(2): 311-319 2011]. The fractal clusters of size R $\sim$ 5-60 nm (polystyrene) have relaxation times $\tau \sim R^{1.8}$ (solid-to-liquid). They are analogous to sub critical size embryos during crystallization as the amorphous material tries to crystallize due to the strong intermolecular forces at $T < T_m$; they are not related to density fluctuations or surface capillary waves. In free-standing thin films of thickness h, several important events occur: (a) The large clusters with R $>$ h are excluded and the thin films have an average faster relaxation time compared to the bulk; consequently T_g decreases as h decreases. (b) The segmental dynamics at the 1 nm scale are largely not affected by nanoconfinement since T_g is determined only by the cluster dynamics with R $\gg$ 1 nm. (c) The mobile layer on the surface of free standing films is due to the presence of smaller clusters on the surface which will disappear with increasing rate of testing. (d) With adhesion to a solid substrate, the surface mobile layer disappears as the surface clusters size grow and the change in T_g is suppressed. (e) Physical aging is controlled by the relaxation of the rigid fractal clusters and in thin films, physical aging will occur more rapidly compared to the bulk. (f) The large effect of molecular weight M on T_g appears to be related to the effect on the cluster size distribution giving smaller clusters and faster relation times with increasing M. These results are in accord with the Twinkling Fractal theory of the glass transition.

10:48AM A34.00013 How does Tg reduction affect the chain mobility in confined PS films? , BULENT AKGUN, Department of Materials Science and Engineering, University of Maryland, MICHAEL DIMITRIOU, SUSHIL K. SATIJA, NIST Center for Neutron Research — It is well established that the glass transition temperature (Tg) of supported polystyrene (PS) thin films decrease with decreasing film thickness. This Tg reduction due to the free surface effect is associated with enhanced mobility. However, the correlation between the enhanced mobility and Tg reduction has not been studied yet. To understand the effect of Tg reduction on the vertical mobility of PS chains across the interfaces we have investigated the interdiffusion between PS and deuterated PS (dPS) films in bilayer and trilayer geometries using neutron reflectivity (NR). Bilayer films of 42 nm thick dPS bottom layer and 20 nm thick PS top layer are created in such a way to mimic the films where large Tg reductions has been demonstrated by recent fluorescence measurements. Trilayer films were created using the same bottom layer but floating a 10 nm thick PS middle layer and 10 nm thick dPS top layer to compare the mobilities at the interfaces between the top/middle and middle/bottom layers. NR results showed that there is almost no mixing between the layers up to 90-95 C for both bilayer and trilayer films which is not consistent with large Tg reductions observed in the literature. Our results also indicate no difference in the mobility of PS chains at the top/middle and middle/bottom interfaces in the trilayer film which argues against the enhanced mobility reported in the literature for the top 10 nm of PS thin films. Diffusion of PS chains across the interface gets faster as the MW decreases.

Monday, March 18, 2013 8:00AM - 10:48AM –

Session A35 DCMP: Superconductivity: Tunneling Phenomena 343 - John Zasadzinski, Illinois Institute of Technology

8:00AM A35.00001 Scanning Tunneling Microscopy of Fe Impurities in $Bi_2Sr_2CaCu_2O_{8+d}$, MICHAEL BOYER, BRIAN KOOPMAN, LING FU, Clark University, W.D. WISE, KAMALESH CHATTERJEE, MIT, GENDA GU, Brookhaven National Laboratory, E.W. HUDSON, Penn State University — We utilize scanning tunneling microscopy measurements to probe the effects of intentionally doped magnetic Fe impurities in the high-temperature superconductor $Bi_2Sr_2CaCu_2O_{8+d}$. Our spectroscopy measurements indicate an absence of particle-hole symmetry in impurity affected regions. In addition, we find evidence that the Fe impurities which substitute for Cu atoms in the CuO_2 plane are shifted from their expected locations. Both of these findings are in contrast to previous STM measurements on magnetic Ni impurities in $Bi_2Sr_2CaCu_2O_{8+d}$ which find spectra which are overall particle-hole symmetric and centered at Cu sites.[1] Interpretations of our measurements may help us understand on a local scale why introduced Fe impurities are more detrimental to superconductivity than Ni impurities as determined by bulk measurements.[2] [1] E.W. Hudson et al., Nature 411, 920 – 924 (2001). [2] T.D. Hien et al., J. Magn. Magn. Mater. 262, 508 – 513 (2003).

8:12AM A35.00002 Can STM detect nematic ordering in underdoped $Bi_2Sr_2CaCu_2O_{8+x}$ or other correlated systems?[1] , EDUARDO DA SILVA NETO, PEGOR AYNAJIAN, Princeton University, SHIMPEI ONO, CRIEPI, Japan, RYAN BAUMBACH, ERIC BAUER, Los Alamos National Laboratory, JOHN MYDOSH, Kamerlingh Onnes Laboratory, Leiden University, ALI YAZDANI, Princeton University — Electronic nematic phases, where, for example, the electronic states undergo a spontaneous four-fold (C_4) to two-fold (C_2) symmetry breaking, have recently gained vast interest as a possible candidate for various hidden order states in several correlated electron systems such as cuprates, pnictides, and heavy fermions. Such states are difficult to detect using non-local probes because of possible twin domain structures in macroscopic samples. STM spectroscopy has been proposed as a possible approach to detect such nematic orders, with several recent experiments reporting signals in the cuprates and iron-based superconductors. We specifically investigate the situation in which STM topographic data shows C_4 symmetry while energy-resolved spectroscopic maps signal C_2 symmetry. We find that such behavior can in fact occur for asymmetric tip geometries and discuss both model calculations and experimental results that provide evidence for this false nematic signature. We discuss possible future STM experiments that could unambiguously detect electronic nematic order.

[1]Work supported by the Office of Basic Energy Science of the DOE and NSF-DMR.

8:24AM A35.00003 STM investigation of incipient order in $Bi_2Sr_2CaCu_2O_{8+x}$, PEGOR AYNAJIAN, EDUARDO H. DA SILVA NETO, Princeton University, SHIMPEI ONO, Komae, Tokyo, JINSHENG WEN, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory, ALI YAZDANI, Princeton University — We investigate the spatial and momentum structure of electronic excitations in underdoped samples of the high-temperature superconductor $Bi_2Sr_2CaCu_2O_{8+x}$ using spectroscopic mapping with the scanning tunneling microscope. A defining feature of the electronic states in these samples is a strong Cu-O bond oriented modulation of the local density of states (Q*). Characterizing Q* as a function of temperature and doping we have established that it appears at the onset of the pseudogap phase at T*, above the regime attributed to fluctuating superconductivity [1]. Model calculations that include both the effects of impurity-induced quasiparticle scattering and incipient order reproduce the energy-dispersion of the measured Q* below and above Tc near optimal doping — where incipient order effects are weak [2]. To extend our understanding to the underdoped samples, we have carried out new high-resolution spectroscopic mapping measurements as a function of doping which more clearly identify the low-energy signatures of the incipient order.

8:36AM A35.00004 Studies of Magnetic Impurities in $Bi_2Sr_2CaCu_2O_{8+\delta}$, EDUARDO CALLEJA, JIXIA DAI, University of Colorado at Boulder, GENDA GU, Brookhaven National Laboratory, KYLE MCELROY, University of Colorado at Boulder — Impurities in high temperatures superconductors, studied with spectroscopic imaging scanning tunneling spectroscopy (SI-STS) have served as a valuable tool to investigate the electronic structure of these materials (E.W. Hudson *et al.*, Nature **411**, 920 (2001), S.H.Pan *et al.*, Nature **403**,746 (2000)). These experiments revealed the appearance of a quasi-localized bound state near the impurity site whose structure is sensitive to the superconducting gap symmetry and the band structure and originates from the charge scattering nature of these impurities. We studied the effects of Fe impurities in $Bi_2Sr_2CaCu_2O_{8+\delta}$ and discovered that the impurities have a different behavior than those previously observed. In particular the quasi bound state near the impurity seems to be behaving as that predicted for a magnetic impurity. The superconducting gap and local electronic density of states was studied in the vicinity of the impurities using SI-STS and will be presented.

8:48AM A35.00005 Persistent electrical doping of Bi2Sr2CaCu2O8+x mesa structures , HOLGER MOTZKAU, THORSTEN JACOBS, SVEN-OLOF KATTERWE, ANDREAS RYDH, VLADIMIR M. KRASNOV, Stockholm University, 106 91 Stockholm, Sweden — We study resistive switching phenomena in small $Bi_2Sr_2CaCu_2O_{8+x}$ (Bi-2212) mesa structures. Applying a significantly large bias voltage or short current pulses, we are able to controllably and reversibly manipulate the normal state resistance and doping state of the same single crystal from an underdoped to the overdoped state without changing its chemical composition. We employ this effect for an analysis of the doping dependence of the electronic spectra of Bi-2212 single crystals by means of intrinsic tunneling spectroscopy. It is observed that such a physical doping is affecting superconductivity in Bi-2212 similar to chemical doping by oxygen impurities: with overdoping the c-axis critical current rapidly increases, while the critical temperature, the superconducting gap and the pseudogap decrease, indicating the presence of the critical doping point. We distinguish two main mechanisms of persistent electric doping: (i) even in voltage contribution, attributed to a charge transfer effect, and (ii) odd in voltage contribution, attributed to reordering of oxygen impurities.

9:00AM A35.00006 Tunneling Spectroscopy of Heavily Underdoped Bi2212 Films , NICKOLAS GROLL, Argonne National Laboratory, CHAOYUE CAO, IIT Chicago and Argonne National Laboratory, MIKE HINTON, THOMAS LEMBERGER, Ohio State University, THOMAS PROSLIER, Argonne National Laboratory, JOHN ZASADZINSKI, IIT Chicago and Argonne National Laboratory — SIS break junctions exhibiting quasiparticle and Josephson tunneling were obtained on heavily underdoped Bi2212 films grown by sputtering, with Tc values as low as 5K. Well defined, but extraordinarily large gap values (Δ) were reproducibly observed, even as the Josephons $I_cR_n \ll \Delta$. The largest values of Δ were close to J, the antiferromagnetic exchange energy. When the new data are combined with previous break junction data on Bi2212 crystals an abrupt change of slope of Δ vs. doping is found, suggesting a second, magnetic energy scale is being observed in the underdoped region.

9:12AM A35.00007 Imaging chemical disorder in cuprates using scanning tunneling microscopy[1] , ILIJA ZELJKOVIC, DENNIS HUANG, CAN-LI SONG, Harvard University, TAY-RONG CHANG, National Tsing Hua University, Taiwan, HORNG-TAY JENG, Institute of Physics, Academia Sinica, Taipei, ZHIJUN XU, JINSHENG WEN, GENDA GU, Brookhaven National Laboratory, JOUKO NIEMINEN, Tampere University of Technology, Finland, ARUN BANSIL, ROBERT MARKIEWICZ, Northeastern University, JENNIFER HOFFMAN, Harvard University — High-T_c cuprate superconductors are chemically, electronically and structurally inhomogeneous at the nanoscale. Although a body of theoretical work has predicted that local and global superconductivity may be dramatically impacted by particular dopant configurations, the exact positions of dopants introduced into cuprates to induce superconductivity are generally unknown. Here we use scanning tunneling microscopy to reveal the intra-unit-cell location of two different types of oxygen dopants in $Bi_{2+y}Sr_{2-y}CaCu_2O_{8+x}$. Furthermore, we show the relationship between these interstitial oxygen dopants, oxygen vacancies, and a global structural buckling known as the supermodulation. We compare our findings to theoretical simulations.

9:24AM A35.00008 Cryomagnetic STM spectroscopy study of multiband pairing in layered superconductors[1] , IGOR FRIDMAN, University of Toronto, VLADIMIR LUKIC, Stevens Institute of Technology, CHRISTIAN KLOC, Nanyang Technological University, Singapore, CEDOMIR PETROVIC, Brookhaven National Laboratory, PENGCHENG DAI, University of Tennessee in Knoxville, J.Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research — Cooper pairing in layered superconductors can involve multiple bands and give rise to complex gap structures in momentum space. Using scanning tunneling microscopy (STM) with a magnetic field applied parallel to the ab-plane, we investigate multiband pairing under diamagnetically-induced superfluid momentum. STM spectroscopy and conductance imaging were performed down to 300 mK and up to 9 T, on single-crystals of the Nb-chalcogenide $2H$-$NbSe_2$ and the Fe-pnictides LiFeAs and electron-doped $BaFe_2As_2$. Spectroscopy data taken on $2H$-$NbSe_2$ at 300 mK showed a distinctly two-sloped field evolution of the zero-bias conductance, consistent with Doppler-induced depairing on parts of the Fermi surface [1]. Spatial conductance maps revealed stripe patterns that originate from in-plane vortices whose cores are buried in the bulk [2] and which undergo a transition as pairing on one of the bands is suppressed. Our results demonstrate a general method for probing multiband superconductors, especially ones whose band structures host coexisting orders and also play a direct role in the pairing mechanism.

9:36AM A35.00009 Doping-dependent vortex-state scanning tunneling spectroscopic (STS) studies of cuprate superconductors , C.-C. CHEN, M. L. TEAGUE, Z.-J. FENG, R.T.-P. WU, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125 — We report STS studies of YBa2Cu3O7$-\delta$(Y-123) and Ca-doped Y-123 superconductors as a function of magnetic field (H) and hole doping level (p). Our studies suggest that the origin of the pseudogap (PG) is associated with competing orders (COs), and that the occurrence (absence) of PG above the superconducting (SC) transition T_c is associated with a CO energy Δ_{CO} larger (smaller) than the SC gap Δ_{SC}. We derive Δ_{SC} and Δ_{CO} by two approaches. For zero-field STS we apply Green function techniques to fit the "peak" features for Δ_{SC} and the "kink" features for $\Delta_{eff} \equiv [(\Delta_{SC})^2 + (\Delta_{CO})^2]^{1/2}$. For $H > 0$ we analyze the PG features in the intra-vortex STS for Δ_{CO} and the peak features in the inter-vortex STS for Δ_{SC}. Both approaches yield consistent results. For optimally and underdoped Y-123, we find that $\Delta_{SC} < \Delta_{CO}$ with dominant $d_{x^2-y^2}$-wave pairing, and that Δ_{SC} decreases with decreasing p while Δ_{CO} increases. Both Δ_{SC} and Δ_{CO} exhibit long-range spatial homogeneity. For Ca-doped Y-123, the substitution of Y by Ca contributes to excess holes and disorder. For $p > 0.16$, both Δ_{SC} and Δ_{CO} decrease with increasing p, $\Delta_{CO} < \Delta_{SC}$ for $p > 0.23$, and the pairing symmetry becomes ($d_{x^2-y^2} + s$) with increasing s-wave component, implying the diminishing Mott nature in overdoped cuprates. This work was supported by NSF through IQIM at Caltech.

9:48AM A35.00010 Spatial Complexity Due to Locally Oriented Charge Modulations in a Cuprate Superconductor , ERICA CARLSON, Purdue University, ELIZABETH MAIN, Harvard University, BENJAMIN PHILLABAUM, Purdue University, HIROSHI IKUTA, Nagoya University, KARIN DAHMEN, University of Illinois, Urbana-Champaign, ERIC HUDSON, Penn State University, JENNIFER HOFFMAN, Harvard University — Surface probes such as scanning tunneling microscopy (STM) have detected complex electronic patterns at the nanoscale in many high temperature superconductors. We use scanning tunneling microscopy to image the local orientation of the static charge modulations in $Bi_{2-y}Pb_ySr_{2-z}LazCuO_{6+x}$, for samples spanning a wide range of doping. For each sample, we compute the universal cluster properties arising from the locally x-oriented and locally y-oriented clusters in order to identify the fundamental physics controlling the complex pattern formation. By comparing these quantitative measures to known universality classes for rotational symmetry breaking, we find that the charge modulations are not confined only to the surface, but they also extend throughout the bulk of the material.

10:00AM A35.00011 Tunneling Spectroscopy of SRF Cavity Grade Niobium , CHAOYUE CAO, Illinois Institute of Technology, Argonne National Laboratory, NICK GROLL, THOMAS PROSLIER, Argonne National Laboratory, JOHN ZASADZINSKI, Illinois Institute of Technology, Argonne National Laboratory — Mechanical contact tunneling measurements are presented on high purity Nb pieces from the starting plate for superconducting radio frequency (SRF) cavity construction as well as from hot spot and cold spot regions of a tested cavity. A varying scattering rate, gamma, is found which broadens the BCS density of states. Detailed fits using Shiba theory indicate that this scattering may be due to magnetic pairbreaking. Hot spot samples reveal a zero bias conductance peak that splits in magnetic field and can be fit using Appelbaum-Anderson theory of spin flip scattering. Together these measurements indicate that the native oxide of Nb can contain varying amounts of localized magnetic moment defects, possibly due to oxygen vacancies in niobium pentoxide.

10:12AM A35.00012 Andreev Reflection Spectra of d-wave Superconductors , CHARLES SNIDER, JESSICA GIFFORD, JONNY MARTINEZ, TINGYONG CHEN, Arizona State University — At a normal metal/superconductor interface Andreev reflection occurs, which can be utilized to measure spin polarization of the normal metal and also the superconducting gap of the superconductor. An s-wave superconductor has an isotropic gap and for an unpolarized current the Andreev reflection spectrum within the gap is twice that of outside the gap. A fully spin polarized current suppresses the Andreev reflection therefore causes zero conductance within the gap. The scenario is quite different in a d-wave superconductor because the order parameter has anisotropy and phase. In this work, we calculate Andreev Reelection spectra of an interface between a normal metal and a d-wave superconductor for a current with any polarization, based on the recent Chen-Tesanovic-Chien (CTC) model. It is shown that the point angle of the interface can drastically change the Andreev spectra and a zero bias anomaly (ZBA) is observed in the tunneling regime only if the point angle is large. The spin polarization can also drastically affect the spectra and can completely suppress the ZBA. Our calculation shows that one can use both the spin polarization and the point angle to verify the ZBA in unconventional superconductors.

10:24AM A35.00013 Direct Probe of Interplay between Local Structure and Superconductivity in FeTe0.55Se0.45 , WENZHI LIN, QING LI, BRIAN SALES, STEPHEN JESSE, ATHENA SAFA-SEFAT, SERGEI KALININ, MINGHU PAN, Oak Ridge National Laboratory, Oak Ridge, TN 37831,USA — We explore the interplay between local crystallographic structure, composition and local electronic and superconductive properties. Direct structural analysis of scanning tunneling microscopy (STM) data allows local lattice distortions and structural defects across a FeTe0.55Se0.45 surface to be explored on a single unit-cell level. Concurrent superconducting gap (SG) mapping reveals suppression of the SG at well-defined structural defects, identified as a local structural distortion (Guinier-Preston zone). The strong structural distortion is related to the vanishing of the superconducting state. This study provides insight into the origins of superconductivity in iron chalcogenides by providing an example of atomic-level studies of the structure-property relationship. Research was supported (WL, BCS, AS, SVK) by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division. This research was conducted (MP, QL) at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy. 10:36AM A35.00014 ABSTRACT WITHDRAWN –

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A36 DMP: Theory and Computation of Novel Superconductivity 344 - Roser Valenti, Universitaet Frankfurt

8:00AM A36.00001 Superconductivity at the onset of spin-density-wave order in a metal[1] , YUXUAN WANG, ANDREY CHUBUKOV, University of Wisconsin-Madison — We revisit the issue of superconductivity at the quantum-critical point between a 2D paramagnet and a spin-density-wave (SDW) metal with ordering momentum (π, π). This problem is highly non-trivial because the system at criticality displays a non-Fermi liquid behavior and because the effective coupling constant λ for the pairing is generally of order one, even when the actual interaction is smaller than fermionic bandwidth. Previous study [M. A. Metlitski, S. Sachdev, Phys.Rev.B 82, 075128 (2010)] has found that the leading renormalization of the pairing vertex contains $\log^2$, like in color superconductivity. We analyze the full gap equation and argue that summing up $\log^2$ term does not lead to a pairing instability. Yet, superconductivity has no threshold, even if λ is set to be small: the subleading $\log$ terms give rise to BCS-like $T_c \propto e^{-1/\lambda}$. We argue that the analogy with BCS is not accidental as superconductivity at a QCP is a Fermi liquid phenomenon – it comes from fermions which retain Fermi liquid behavior at criticality. We compute T_c for the actual λ and find consistency with the numerical results.

8:12AM A36.00002 Coexistence of Antiferromagnetism and Superconductivity in Bilayer Cuprates and Iron Arsenides , TAKAMI TOHYAMA, HIROYUKI YOSHIZUMI, YASUNORI MATSUI, Yukawa Institute for Theoretical Physics, Kyoto University, TAKAO MORINARI, Department of Interdisciplinary Environment, Kyoto University — The coexistence of antiferromagnetism (AFM) and superconductivity (SC) is one of important issues in strongly correlated electron systems. One example is seen in multilayered cuprate superconductors, and another one is in iron-arsenide superconductors. In cuprates, motivated by the recent experiment reporting the enhancement of AFM order below the SC transition temperature, we study the proximity effect of the AFM correlation in a bilayer system and also examine the possibility of the coexistence. We present the result of mean-field theory that is consistent with the experiment and supports the proximity-effect picture [1]. In iron arsenides, we study possible coexistence of AFM with Dirac dispersions and SC with the same and different phase of pairing potential, based on the knowledge of the cuprates. [1] Y. Yoshizumi, T. Morinari, and T. Tohyama, Phys. Rev. B **85**, 184523 (2012).

8:24AM A36.00003 Robust nodal d-wave spectrum in simulations of strongly fluctuating competing order in underdoped cuprates[1] , WILLIAM ATKINSON, Trent University, J. DAVID BAZAK, McMaster University, BRIAN ANDERSEN, Neils Bohr Institute — While many experiments suggest that the pseudogap in cuprate superconductors originates from some nonsuperconducting broken-symmetry phase, clear spectral signatures of such a phase have not been observed in angle resolved photoemission experiments. We report on numerical simulations of the spectral function, in which competing superconducting and nonsuperconducting phases experience strong thermal fluctuations. In our work, we consider the competition between d-wave superconductivity and a low temperature spin density wave (SDW) phase that is widely observed in underdoped cuprates. Because of this competition, our simulations sample highly inhomogeneous states that are far from the mean-field saddle point configurations. We find that the computed spectral function is, in many cases, almost indistinguishable from that of the pure d-wave superconductor, and that there is no sign of the Fermi surface reconstruction generically expected for SDW phases. We argue that this work explains the absence of any clear experimental signature of such a reconstruction. We find that signatures of the fluctuating competing order can be found mainly in a splitting of the antinodal band and, for strong magnetic order, in small induced nodal gaps similar to those found in recent experiments

8:36AM A36.00004 Theory of nonequilibrium superconductivity in cuprates , TAKASHI OKA, Department of Applied Physics, The University of Tokyo, VILLE PIETILÄ, Department of Applied Physics, Aalto University — Recently, nonequilibrium properties of Hi Tc superconductors are attracting much interest. This is because new experimental methods such as time resolved ARPES has been applied to cuprates and succeeded in observing the dynamics of photo-excited quasiparticles as well as the temporal evolution of the d-wave superconducting order parameter (e.g., [1]). One can also realize nonequilibrium states in interfaces between cuprates and metal electrodes and control the superconducting order by changing the applied bias [2]. In order to study the dynamics of superconductivity in strongly correlated systems, we developed a novel numerical method by combining the quantum kinetic equation with the fluctuation exchange approximation (FLEX, self-consistent T-matrix approximation) [3]. This method enables us to study the interplay between pair mediating fluctuations, e.g., antiferromagnetic and charge fluctuations, and the dynamics of quasiparticles and superconducting order parameter. In the presentation, we explain the physical insights we obtain by applying this method to nonequilibrium dynamics in d-wave superconductors.

8:48AM A36.00005 Pair density wave superconducting state in a Nematic Liquid Crystal Phase[1] , RODRIGO SOTO GARRIDO, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We consider the problem of the superconducting states that arise in a fermionic system in a nematic-like $l = 2$ state in the spin-triplet channel. This nematic state is invariant under a $\pi/2$ rotation followed by a spin flip. Under these circumstances the only infinitesimal superconducting instability is in the p-wave channel. However, close enough to the nematic transition both a uniform d-wave superconducting state and a pair density wave (PDW) state (also with d-wave symmetry) can arise. We compute the phase diagram and study the competition between an uniform (BCS type) superconducting state, the PDW state and the non-superconducting state.

[1]This work was supported in part by DOE under contract No. DE-FG02-07ER46453 at the University of Illinois.

9:00AM A36.00006 Incommensurate Nematic Charge Order in the Three Band Model for Cuprate Superconductors[1] , SINAN BULUT, Trent University / Queen's University, WILLIAM A. ATKINSON, Trent University, ARNO KAMPF, Center for Electronic Correlations and Magnetism, Theoretical Physics III, Institute of Physics, University of Augsburg, — Recent experimental evidence for charge order in cuprates is a possible source of anomalous electronic properties in the underdoped regime. Intra-unit cell charge ordering tendencies point to electronic nematic order involving oxygen orbitals. In this context we investigate charge instabilities in the Emery model. The charge susceptibilities reveal three different kinds of nematic order. The first is an intra-unit cell ($q = 0$) nematic order. The second and the third are incommensurate charge orders with wavevectors that are either uniaxial or oriented along the Brillouin zone diagonal. The two latter charge patterns correspond to a spatially modulated nematic phase. The selection of the leading instability depends on the filling, the interaction parameters, and details of the band structure. For these candidate charge orderings we discuss their possible relevance for the charge ordering signatures in X-ray and STM experiments.

9:12AM A36.00007 Orbital Nematic Instability in Two-Orbital Hubbard Model: A Renormalization-Group Study , MASAHISA TSUCHIIZU, Department of Physics, Nagoya University, Japan, SEIICHIRO ONARI, Department of Applied Physics, Nagoya University, Japan, HIROSHI KONTANI, Department of Physics, Nagoya University, Japan — Motivated by the nematic electronic fluid phase in $Sr_3Ru_2O_7$, we analyze the (d_{xz}, d_{yz})-orbital Hubbard model by the one-loop renormalization-group method [1]. We find that, in the weak-interaction case, the $q = 0$ component of the orbital susceptibility $\chi^{\rm q}(q)$ is critically enhanced by the Aslamazov-Larkin (AL) type vertex correction due to the superconducting fluctuations. In the strong-interaction case, we also find the development of $\chi^{\rm q}(q)$ driven by the AL-type vertex correction due to spin fluctuations, consistently with the perturbation analysis [2]. Thus the strong orbital nematic fluctuation, i.e., orbital Pomeranchuk instability, emerges near the magnetic or superconducting quantum criticality. This mechanism of orbital nematic order presents a natural explanation for the nematic order in $Sr_3Ru_2O_7$, and is expected to be realized in various multiorbital systems, such as Fe-based superconductors [3].

9:24AM A36.00008 Superconductivity in CuCl/Si superlattices: excitonic pairing?[1] , S.H. RHIM, Northwestern University, ROLANDO SANIZ, University Antwerpen, MICHAEL WEINERT, University Wisconsin-Milwaukee, A.J. FREEMAN, Northwestern University — Two-dimensional (2D) hetero-bonded semiconductor interfaces have been suggested as candidate geometries where excitonic superconductivity [2] – and the greatly enhanced where T_C compared to phonon mechanisms mediation – can be realized. Among experimental efforts, epitaxially grown CuCl on Si (111) has reportedly exhibited excitonic superconductivity at 60∼150 K. Our first-principles calculations confirm 2D metallicity at the interfaces due to charge transfer by valence mismatch. [3] The excitonic mechanism is investigated by calculating the kernel function, $K(\omega)$, for the average of the electronic contributions to the effective interaction.[4] The attractive interaction found in the CuCl/Si superlattice indicates the feasibility of excitonic pairing for a certain frequency range.

9:36AM A36.00009 ABSTRACT WITHDRAWN –

9:48AM A36.00010 Real-Space Holon Pairing in Underdoped Cuprates[1] , TIMOTHY LOVORN, SANJOY SARKER, University of Alabama — We examine the behavior of a recently developed model for underdoped cuprates [1] in the fluctuation regime above T_c. It is characterized by a spin gap and describes sublattice preserving hopping by holons and holon pairs, accompanied by a backflow of spin singlets. The singlets form a short-range valence-bond state which is continuously connected to the correct spin state at half filling. The theory, thus constrained, leads to the correct phase diagram and also explains the two-dimensionality of the metallic states. Superconductivity is due to pair hopping, as holons form real-space pairs at low densities and undergo a Bose-Einstein condensation below T_c. The pairs exist up to a temperature $T_p > T_c$, which is consistent with the observed Nernst effect and diamagnetism above T_c. The pair spectrum is calculated by identifying poles of the pair Green's function. Here we show that the specific heat of this system is in qualitative agreement with recent measurements [2].

10:00AM A36.00011 Analyses of High-Temperature Superconductivity in Doped Hubbard Model –High-Precision Variational Monte Carlo Study– , TAKAHIRO MISAWA, MASATOSHI IMADA, Dept. of Applied Physics, Univ. of Tokyo — Two-dimensional Hubbard model, which only includes the on-site Coulomb interaction U and the nearest hopping t, is one of the simplest models proposed for describing the high-T_c superconductivity. Although numerically unbiased methods such as auxiliary-field quantum Monte Carlo(QMC)[1] and Gaussian-basis QMC [2] do not find an indication for the superconductivity for intermediate coupling region($U/t < 8$), several approaches such as the variational Monte Carlo(VMC) method[3,4] suggest that the d-wave superconductivity appears in the doped Hubbard model. To quantitatively resolve the origin of the controversy and to reveal the superconducting mechanism, by using a high-precision VMC[5], we present results which successfully reproduces the results of previous unbiased calculations[1,2], while finds the superconductivity in a strong coupling region. We focus on the relation of the superconductivity to proximity of phase separation with charge fluctuations as its mechanism. [1]N.Furukawa and M.Imada, J. Phys. Soc. Jpn. 61, 3331 (1992). 10:12AM A36.00012 Superconductivity in two-leg ladder iron selenides , WEICHENG LV, ELBIO DAGOTTO, Department of Physics and Astronomy, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, GEORGE MARTINS, Department of Physics, Oakland University — Recently, evidence of superconductivity has been discovered in the single-layer potassium-doped iron selenide that consists of weakly coupled two-leg iron ladders (Wei Li *et al.*, arXiv:1210.4619). Using a self-consistent mean-field approximation, we analyze the pairing symmetry and structure of the multi-orbital t-J model defined in these two-leg ladder systems. Similar to the case of the iron pnictides, a modified s-wave pairing state is stabilized by the next-nearest-neighbor superexchange J_2. The presence of competing states will be discussed. Our result demonstrates the potential importance of the local magnetic couplings in iron-based superconductors.

10:24AM A36.00013 Magnetic States of the Two-Leg Ladder Iron Selenides , QINLONG LUO, ANDREW NICHOLSON, JULIAN RINCON, SHUHUA LIANG, ADRIANA MOREO, ELBIO DAGOTTO, Univ. of Tennessee/ORNL, JOSE RIERA, Universidad Nacional de Rosario, GONZALO ALVAREZ, ORNL, LIMIN WANG, WEI KU, BNL — Neutron scattering experiments have unveiled a dominant spin arrangement in the two-leg ladder selenide compound $BaFe_2Se_3$, involving ferromagnetically ordered 2×2 iron-superblocks, that are antiferromagnetically coupled among them (the "block-AFM" state). Our numerical study of the electronic five-orbital Hubbard model, within the Hartree-Fock approximation and using first principles techniques for the hopping amplitudes, has shown that the exotic block-AFM state is indeed stable at realistic electronic densities $n \sim 6.0$. Another state with wavevector $(\pi, 0)$ becomes stable in other portions of the phase diagrams, including $n \sim 5.5$, as found experimentally in KFe_2Se_3. In addition, our study unveils several competing magnetic phases that could be experimentally stabilized varying either n chemically or the electronic bandwidth by pressure. Similar results were obtained using two-orbital models, studied here via Lanczos and DMRG techniques [1]. [1] Qinlong Luo, et al, arXiv: 1205.3239, and references therein.

10:36AM A36.00014 Second Corollary to the Five Principles of Photoemission Via Dipolon Theory of High Temperature Superconductivity , RAM R. SHARMA, University of Illinois at Chicago — Recently, we presented theory of dipolon-phonon interaction to explan the isotope shift in HTSC. Also we deduced five principles with one corollary [1] of photoemission (PE) from the dipolon theory [2,3] which not only explained the peak-dip-hump phenomenon [4] and low energy kink in quasiparticle energy dispersion (QED) but also predicted two more high energy kinks [1,4] that have now been observed. Here we present second corollary to the five principles of PE which states: "As one changes dipolon density of states by changing or creating interactions with the factors such as doping, occupation number of ions, vacancies, defects, impurities, phononS with and without different isotope exchange, lattice structure, lattice distortion etc. there appear corresponding changes (shifts) in PE spectra, T_C, QED and the kink structure (predictably, one may observe the apparent isotope shift negative as well as zero or positive depending on the simultaneous action of the other factors)."

10:48AM A36.00015 Different roles of Zn^{2+} and Li^{+} impurities in the CuO2 plane in undoped cuprate compounds , JIAWEI MEI, Institute for Theoretical Physics, ETH Zurich — A planar Mott insulator with easy plane Neel order can be mapped unto a Gutzwiller projected topological insulator model. Under the assumption that the projection operator can be permuted, Zn^{2+} and Li^{+} impurities can be represented as vacancies introducing a zero mode, which has a local spin moment for Zn^{2+} and a charged hole for Li^{+}, respectively. While the local spin moment for Zn^{2+} is screened by the long-range spin correlations, the active charge degree of freedom for Li^{+} impurity twists the spin background. This proposal explains the very different roles of the Zn^{2+} and Li^{+} impurities in the CuO2 plane in the undoped cuprate compounds.

Session A37 DMP DCOMP: Focus Session: Fe-based Superconductors: Coexistence with Magnetism 345/346 - Ulrich Welp, Argonne Natl Lab

8:00AM A37.00001 Various forms of coexistence of superconductivity and magnetism in iron-pnictide superconductors: a NMR study[1] , JULIEN BOBROFF, Laboratoire de Physique des Solides, Universite Paris Sud & CNRS, Orsay, France — Our NMR studies of iron pnictides allowed us to discover various forms of coexistence between superconductivity and magnetism. In Co-doped BaFe2As2, superconductivity and incommensurate antiferromagnetism coexist at the atomic level in an homogeneous state. In contrast, Ru isovalent doping leads to a disorderd situation where superconducting clusters appear in an antiferromagnetic background. Finally, in the 245 iron-selenide RbFeSe, antiferromagnetism and superconductivity separate in alternate layers of nanometer thickness. But in all these componds, the superconducting state remains similar in terms of local susceptibility and carrier doping. It looks as if, for superconductivity to appear, frozen Fe magnetic moments need to be small enough or far enough in distance, whatever the cause. Y. Texier et al., PRL 108, 237002 (2012); Y. Laplace et al., PRB Rapid Com 86, 020510(R) (2012); Y. Laplace, PRB Rapid Com 80, 140501 (2009)

8:36AM A37.00002 Nuclear magnetic resonance studies of coexisting antiferromagnetism and superconductivity in $Ba(Fe_{1-x}Co_x)_2As_2$, ADAM DIOGUARDI, JOHN CROCKER, ABIGAIL SHOCKLEY, NICHOLAS APROBERTS-WARREN, CHING LIN, KENT SHIRER, DAVID NISSON, UC Davis, ALEX THALER, PAUL CANFIELD, Ames Laboratory, NICHOLAS CURRO, UC Davis — We present ^{75}As nuclear magnetic resonance (NMR) spectra and spin lattice relaxation data from $Ba(Fe_{1-x}Co_x)_2As_2$ for $x = 0.05757$, 0.05898, and 0.06163, with $T_C = 21.5$ K, 22 K, and 22.7 K respectively. The spectra become broadened below the antiferromagnetic (AFM) phase transition. Spin lattice relaxation was measured by inversion recovery at the central line with $H \perp \hat{c}$ down to 4.5 K into the coexistence region. As temperature is decreased toward the AFM phase transition, the exponential inversion recovery curve begins to deviate from the theoretical prediction. The curves were fit to a stretched exponential to characterize this deviation as a function of temperature. This behavior persists into the coexistence region and may be related to nematic fluctuations.

8:48AM A37.00003 Novel Phase Separation and Magnetic Volume Tuning in Underdoped $NaFe_{1-x}Co_xAs$ ($x \simeq 0.01$) , LONG MA, J. DAI, X.R. LU, Department of Physics, Renmin University of China, GUOTAI TAN, YU SONG, Department of Physics and Astronomy, The University of Tennessee, PENGCHENG DAI, Department of Physics and Astronomy, The University of Tennessee Institute of Physics, Chinese Academy of Sciences, C.L. ZHANG, Department of Physics and Astronomy, The University of Tennessee, B. NORMAND, WEIQIANG YU, Department of Physics, Renmin University of China — NaFeAs is a quasi-2D pnictide parent compound with a weak magnetic moment and separate structural and antiferromagnetic transitions. Because Co doping leads to a superconductor with $T_c \simeq 20$ K at a very low optimal doping of $x = 0.02$, $NaFe_{1-x}Co_xAs$ is uniquely suited to sensitive studies of the cohabitation and competition between magnetism and superconductivity. Using NMR as a local probe of both antiferromagnetic order and superconductivity, we have compared Knight shifts and relaxation rates on the Na, As, and Co nuclei. Above T_c, we find weak doping inhomogeneity, in the form of residual paramagnetic regions with differing T_N values, and a strongly field-controlled magnetic volume. Below T_c, we observe a strong competition between antiferromagnetism and superconductivity, in which the temperature is the dominant control parameter, suppressing the magnetic volume fraction very significantly in favor of the superconducting one, while the external field suppresses T_c. Our results suggest both a microscale phase separation in real space and in reciprocal space a competition between two order parameters requiring the same electrons on the quasi-2D Fermi surface.

9:00AM A37.00004 ^{75}As and ^{23}Na NMR study in optimally Co doped $NaFe_{0.975}Co_{0.025}As$[1] , SANGWON OH, A.M. MOUNCE, JEONGSEOP A. LEE, W.P. HALPERIN, Northwestern University, C. L. ZHANG, PENGCHENG DAI, The University of Tennesee, A.P. REYES, P.L. KUHNS, National High Magnetic Field Laboratory — The normal and superconducting state of $NaFe_{0.975}Co_{0.025}As$, single crystals with exceptionally narrow ^{75}As and ^{23}Na NMR spectra, were investigated in external magnetic fields from 6.4 T to 24 T. The Knight shift (^{75}K) shows an almost linear decrease in the normal state on cooling and a sharp transition to spin-singlet superconductivity below T_c. A temperature independent ^{75}K at low temperature, below 0.4 T_c, indicates that there are no gap nodes. The penetration depth, λ_{ab}, was found to be 456 $\pm$ 7 nm at zero temperature, after convoluting the normal state spectrum with the vortex field distribution expected from Ginzburg-Landau theory. The spin lattice relaxation rate, $1/T_1$, shows a T^3 behavior in the superconducting state at low field which becomes $T^{1.5}$ at higher fields. Additionally, the average of $1/T_1$ over the vortex unit cell at T = 4 K is linear in H^2.

9:12AM A37.00005 Structural and magnetic phase transitions in TbRuAsO and DyRuAsO[1] , MICHAEL MCGUIRE, ANDREW MAY, OVIDIU GARLEA, BRIAN SALES, Oak Ridge National Laboratory — The compounds *Ln*RuAsO (*Ln* = lanthanide) are isoelectronic, isostructural, 4*d* transition metal analogues of the parent phases of 1111-type iron superconductors, but display markedly different behaviors. Recent results from crystallographic and physical properties measurements on TbRuAsO and DyRuAsO reveal particularly unusual properties in these materials. Analysis of low temperature x-ray and neutron powder diffraction data indicate a symmetry-lowering crystallographic phase transition in DyRuAsO at 25 K, and ordering of rare-earth magnetic moments at 7.0 and 10.5 K for TbRuAsO and DyRuAsO, respectively. The structural distortion observed in DyRuAsO (to space group P*mmn*) is different than the well-known distortion that occurs in *Ln*FeAsO. In addition, the findings indicate some coupling between the magnetism and the lattice, and hints of Ru magnetism are observed. A response to the structural transition is apparent in the magnetic susceptibility, and the associated heat capacity anomaly responds strongly to a magnetic field.

9:24AM A37.00006 Structural and magnetic properties of $Ba_{1-x}Na_xFe_2As_2$, OMAR CHMAISSEM, Northern Illinois University and Argonne National Laboratory (ANL), S. AVCI, Bursa technical University, Turkey, R. OSBORN, S. ROSENKRANZ, H. CLAUS, D.Y. CHUNG, ANL, M. KANATZIDIS, ANL and Northwestern University, D.D. KHALYAVIN, P. MANUEL, ISIS, Rutherford Appleton Laboratory, UK — Iron pnictides have attracted significant intrigue because of their astonishing superconducting properties in a large number of materials that support chemical substitutions at literally every site. Of particular interest is AFe2As2 (A= Ba, Sr, Ca) in which hole or electron-doping is achieved by chemical substitution of alkaline or transition metal elements at the Ba and Fe sites, respectively. Nominally isovalent P substitutions for As have also been achieved producing a phase diagram remarkably similar to the electron- or hole-doped diagrams. A universal picture has emerged: a spin density wave region is stable at low substitution levels in which the Fe magnetic moments are aligned antiferromagnetically along the a- and c-axes and ferromagnetically in the direction of the b-axis. With increased substitution, the magnetic structure progressively loses strength to a point where it's suppressed in favor of superconductivity usually extending over a broad substitution range to form a superconducting dome. In these 122 systems, samples with compositions in the crossover region have been demonstrated by neutron diffraction and other techniques to allow the microscopic coexistence of both magnetism and superconductivity. I will present insights on the structural and magnetic properties of the $Ba_{1-x}Na_xFe_2As_2$ system and discuss the results in a general context.

9:36AM A37.00007 Synthesis, structure and magnetic properties of $BaFe_2(As_{1-x}P_x)_2$ as determined by elastic and inelastic neutron scattering , KEITH M. TADDEI, Northern Illinois University, J.M. ALLRED, R. OSBORN, S. ROSENKRANZ, D. BUGARIS, H. CLAUS, Argonne National Laboratory (ANL), M. KANATZIDIS, ANL and Northwestern University, S. AVCI, Bursa technical University, Turkey, C. DE LA CRUZ, Oak Ridge National Laboratory, O. CHMAISSEM, Northern Illinois University and ANL — Unconventional superconductivity and microscopic phase coexistence have been demonstrated in a narrow compositional region of the122 system between two competing spin density wave and superconducting order parameters. Quantum critical fluctuations induced by the suppression of the antiferromagnetic order have been proposed to mediate pairing in analogy with the role played by phonons in conventional cuprates. Establishing unambiguous conclusions concerning the pairing mechanism has proven difficult in the pnictides due to the complexity of the electronic structures. Recent reports have shown that isovalent P substitution for As in $BaFe_2As_2$ suppresses the structural and magnetic transitions and lead to superconductivity similar to hole or electron doping. From the chemical point-of-view, there is no net change in the electron-to-hole ratio in this charge compensated system. I will briefly discuss synthesis details of high quality pnictides and $BaFe_2(As_{1-x}P_x)_2$ samples and present structural results obtained by neutron diffraction. Inelastic neutron measurements will also be discussed.

9:48AM A37.00008 The phase diagram of $BaFe_2(As_{1-x}P_x)_2$ as determined by neutron diffraction , JARED ALLRED, KEITH TADDEI, DANIEL BUGARIS, SEVDA AVCI, OMAR CHMAISSEM, Argonne National Lab, CLARINA DELA CRUZ, Oak Ridge National Lab, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, STEPHAN ROSENKRANZ, RAY OSBORN, Argonne National Lab — The iron-arsenides are a now famous family of high-T_c superconductors where the superconducting state is stabilized by suppressing a magnetic ground state in a parent compound. The phenomenon is quite robust, and $BaFe_2As_2$, for example, can be made superconducting either by applying pressure or by electron, hole, or isovalent doping. The isovalently doped $BaFe_2(As_{1-x}P_x)_2$ materials are particularly interesting because it is not obvious what is driving the suppression of the SDW and enhancing T_c. The driving force has been variously ascribed to chemical pressure, changes in polarity of the Fe-(As,P) bond, and other even more subtle chemical effects. Moreover, reports on various general features in the iron-arsenide phase diagram—such as short-range nematic order and the separation of the Néel transition (T_N) and the structural transition (T_s)—remain contradictory and underexplored. We have undertaken a detailed neutron diffraction study of the phase diagram in order to clarify some of the ambiguities. We find that $T_s = T_N$ and that the superconducting dome rises more sharply than for the aliovalently doped materials. Moreover, the T dependence of the structural and magnetic order parameters and a discontinuous increase in c/a below T_N suggest a first order phase transition.

10:00AM A37.00009 Magnetic neutron diffraction study of $BaFe_{2(1-x)}Co_{2x}As_2$ critical exponents through the tricritical doping , D.M. PAJEROWSKI, National Institute of Standards and Technology Center for Neutron Research, C.R. ROTUNDU, Materials Science Division, Lawrence Berkeley National Laboratory, J.W. LYNN, National Institute of Standards and Technology Center for Neutron Research, R.J. BIRGENEAU, Department of Physics, Department of Materials Science and Engineering, University of California, Berkeley — We present temperature dependent magnetic neutron diffraction measurements of $BaFe_{2(1-x)}Co_{2x}As_2$ for x = 0.039, 0.022, and 0.021 as-grown single crystals. We are motivated to investigate the magnetic tricritical point in the (x,T) plane near $x_{tr}^m \approx 0.022$,[1] as well as to systematically probe the character of the magnetic phase transition across a range of dopings. All samples show long range antiferromagnetic order that may be described near the transition by $I \propto (1 - T/T_N)^{2\beta}$ with $\beta = 0.291$ for x = 0.039, $\beta = 0.208$ for x = 0.022, and $\beta = 0.198$ for x = 0.021, showing a monotonic increase from the parent $BaFe_2As_2$ compound, $\beta = 0.103$.[2] We will discuss the results based on theoretical predictions for the behavior of the order parameter in the vicinity of a tricritical point.

[2] S.D. Wilson, Z. Yamani, C.R. Rotundu, B. Freelon, E. Bourret-Courchesne, and R.J. Birgeneau, Phys. Rev. B 79, 184519 (2009).

10:12AM A37.00010 First order quantum phase transition under the superconducting dome of $Ba(Fe_{1-x}Co_x)_2As_2$[1] , T. HU[2], H. XIAO[3], Y.P. SINGH, D.J. HANEY, X.Y. HUANG, M. DZERO, Kent State University, USA, H.H. WEN, Nanjing University, China, C.C. ALMASAN, Kent State University, USA — We present the results of magnetoresistivity and magnetization measurements performed under pressure (P) on single crystals of $Ba(Fe_{1-x}Co_x)_2As_2$ (x = 0, 0.042, 0.06, 0.08). Our results show that the antiferromagnetic phase macroscopically coexists with the superconducting phase and can be induced by the magnetic field locally nucleated in the vortex core for the x = 0.06 sample. In addition, the diamagnetic signal of the x = 0.06 sample shows a huge jump around P = 0.5 GPa, where the superconducting transition temperature displays a maximum. This suggests that a first order antiferromagnetic quantum phase transition (QPT) is present inside the superconducting dome, and that the superconductivity in this system is closely related to this QPT. A magnetic tricritical point is observed inside the superconducting dome, and no quantum critical point is expected in zero magnetic field.

10:24AM A37.00011 Intermediate orthorhombic phases in Ba-122 Iron Arsenides[1] , J.P.C. RUFF, CHESS, Cornell University, Z. ISLAM, R.K. DAS, The Advanced Photon Source, Argonne National Lab, H.-H. KUO, I.R. FISHER, Stanford University — Despite widespread interest, there are details of the tetragonal-orthorhombic structural phase transition in the iron arsenide superconductors that remain controversial. We have revisited the transition in three characteristic compositions of the canonical "122" family $Ba(Fe/Co)_2(As/P)_2$ using single crystal synchrotron x-ray diffraction. In the parent compound, we confirm previous observations of a sequence of structural transitions which are closely spaced in temperature, and uncover pronounced magnetoelastic effects in the intermediate orthorhombic phase. Modification of the structural transitions by doping is observed to differ significantly depending on whether the dopant is Co or P.

[1]Work performed at the Advanced Photon Source was supported by the DOE, under Contract No. DE-AC02-06CH11357.

10:36AM A37.00012 Effects of the adjacent antiferromagnetic layer on superconductivity for the case of $K_yFe_{2-x}Se_2$, SHIN-MING HUANG, CHUNG-YU MOU, Department of Physics, National Tsing Hua University, Hsinchu 30043, Taiwan, TING-KUO LEE, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan — A mesoscopic phase separation of superconductivity and antiferromagnetism has been recently reported as a prominence in ternary iron selenides. The iron vacancy is free in the superconducting (SC) segment, but clusters and forms order in the antiferromagnetic (AFM) segment. In this report we use a two-orbital model of one AFM layer coupled with another vacancy-free layer for superconductivity and study the effects of the interlayer coupling and the AFM order on SC instability. The SC instability is evaluated by solving the Bethe-Salpeter equation within a local pairing model. Since two individual layers have different Fermi surface (FS) structures, when coupled the FS topography will change depending on the interlayer coupling and the AFM order. We demonstrate that the superconductivity is more stable when FS sheets are disconnected. Interlayer coupling will deteriorate superconductivity and its effect becomes weak when the AFM moment is saturated. Due to lack of reflection symmetry, the SC gap is highly anisotropic and the presence of accidental nodes on disconnected FS sheets of d-wave superconductivity is possible.

10:48AM A37.00013 Resonance peak of neutron scattering in iron-based superconductors , SEIICHIRO ONARI, Department of Applied Physics, Naogya University, YUSUKE OHNO, MASAHISA TSUCHIIZU, HIROSHI KONTANI, Department of Physics, Naogya University — Recently, nematic electronic states had been discovered in various strongly correlated metals such as iron-based superconductors, $Sr_3Ru_2O_7$ and heavy fermions. These phenomena originate from the electron-electron correlation, since the lattice distortions are very small. Interestingly, many of these materials exhibit unconventional superconductivity, suggesting that the fluctuations of the nematic order parameter would cause the superconductivity. The origin of the nematic states had been unsolved since they cannot be explained by the mean-field approximation. Here, we study this issue beyond the mean-field approximation. We calculate the vertex correction (VC) for the irreducible susceptibility in various multiorbital Hubbard models, and derive the spin and orbital fluctuations self-consistently [1,2]. Near the magnetic quantum critical point, it is found that strong ferro- and antiferro-orbital fluctuations are induced by the VC in both iron-based superconductors and $Sr_3Ru_2O_7$. The divergence of the ferro-orbital fluctuations presents the orbital nematic state in these materials. [1] S. Onari and H. Kontani, Phys. Rev. Lett. 109, 137001 (2012). [2] Y. Ohno, M. Tsuchiizu, S. Session A38 GIMS: Focus Session: Instrumentation and Measurement Science for a Sustainable Energy Future 347 - Eric Palm, National High Magnetic Field Laboratory, Tallahassee

8:00AM A38.00001 Our Sustainable Earth , RAYMOND L. ORBACH, The University of Texas at Austin — Recent evidence demonstrates that the Earth has been warming monotonically since 1980. Transient to equilibrium temperature changes take centuries to develop, as the upper levels of the ocean are slow to respond to atmospheric temperature changes. Atmospheric CO_2 concentrations, from ice core and observatory measurements, display consistent increases from historical averages, beginning in about 1880. They can be associated with the use of coal ecause of the spread of the industrial revolution from Great Britain to the European continent and beyond. The climactic consequence of this human-dominated increase in atmospheric CO_2 has been suggested to define a geologic epoch, termed the "Anthropocene." This could be a short term, relatively minor change in global climate, or an extreme deviation that lasts for thousands of years. In order to stabilize global temperatures, sharp reductions in CO_2 emissions are required: an 80% reduction beginning in 2050. U.S. emissions have declined sharply recently because of market conditions leading to the substitution of natural gas for coal for electricity generation. Whether this is the best use for this resource may be questioned, but it nevertheless reduces CO_2 production by 67% from a coal-fired power plant, well on the way to the 80% reduction required for global temperature stabilization. Current methods for CO_2 capture and storage are not cost effective, and have been slow (if not absent) to introduce at scale. This paper describes research into some potentially economically feasible approaches: cost-effective capture and storage of CO_2 from injection of flue gas into subterranean methane-saturated aquifers at the surface; fuels from sunlight without CO_2 production; and large-scale electrical energy storage for intermittent (and even constant) electricity generating sources.

8:36AM A38.00002 High-Performance Electrocatalysts for Oxygen Reduction Derived from Polyaniline, Iron, and Cobalt[1] , PIOTR ZELENAY, Los Alamos National Laboratory — With the growing awareness that the use of platinum needs to either be greatly reduced or completely eliminated from the polymer electrolyte fuel cell (PEFC), non-precious metal catalysts for oxygen reduction reaction (ORR) have received lots of attention in recent years as a possible replacement of Pt and its alloys at the fuel cell cathode. A successful cathode catalyst must combine high ORR activity with good long-term stability – a major challenge in the strongly acidic environment of the PEFC cathode. In response to the possibly greatest challenge of the PEFC technology, we have developed a family of non-precious metal ORR catalysts capable of minimizing the performance gap to platinum-based catalysts at a cost sustainable for high-power fuel cell applications, possibly including the automotive power plant. The approach utilizes polyaniline (PANI) as a precursor of a carbon-nitrogen template for high-temperature synthesis of catalysts in the presence of transition metals (Fe and/or Co). The most active materials in the group allow for the ORR to occur within ca. 60 mV of the potential delivered by a state-of-the-art carbon-supported Pt catalyst. A distinctive combination of (i) high ORR activity, (ii) unique performance stability for non-precious metal catalysts (more than 700 hours at a fuel cell voltage of 0.4 V), and (iii) excellent four-electron selectivity (H_2O_2 yield less than 1.0%), make the leading catalyst in this group, PANI-FeCo(3:1), the best overall non-precious metal ORR catalyst studied to date. More recently, we have also focused on better understanding of the active ORR site via the use of advanced surface characterization techniques, such as nuclear resonance vibrational spectroscopy (NRVS), Monte Carlo pre-screening of possible active sites and more advanced DFT modeling of the most likely active-site structures. Combination of the experiment and theory is expected to aide in the rational design of the future ORR catalysts.

[1]Financial support from Los Alamos National Laboratory (LDRD Program) and US Department of Energy (Hydrogen and Fuel Cells Program) is gratefully acknowledged.

9:12AM A38.00003 Modulated photocurrent spectroscopy of thin film solar cells , BEHRANG HAMADANI, JOHN ROLLER, EL, NIST, PANAGIOTIS KOUNAVIS, University of Patras, NIKOLAI ZHITENEV, CNST, NIST, DAVID GUNDLACH, PML, NIST — We used the modulated photocurrent spectroscopy technique based on sinusoidal excitation of high-powered LEDs to investigate the dynamic response of charge carrier transport in thin film solar cells based on CdTe. The impact of light bias, voltage bias and the temperature over a broad excitation frequency bandwidth were studied. The observed features of the data, including a photocurrent phase-lead and a phase-lag over different regions of the frequency spectrum, were explored in the context of an equivalent circuit model. Comparisons between the model's predicted performance and the measured data suggest that charge carrier recombination at the cell's back metal/semiconductor contact is the main source of photocurrent loss in the cells that were investigated by our group.

9:24AM A38.00004 Ultrasensitive spectroscopy of ultrasmall quantum dots for energy conversion and lighting applications , LLOYD DAVIS, Center for Laser Applications, University of Tennessee Space Institute, NOAH ORFIELD, SANDRA ROSENTHAL, Department of Chemistry, Vanderbilt University — Quantum dots typically have narrow spectra with a peak that tunes with their size but ultrasmall semiconductor nanocrystals of diameters less than a few nanometers have size-independent spectra and many other strikingly different properties. One especially interesting feature is that ultrasmall CdSe nanocrystals emit an almost pure white-light spectrum, which has great potential for solid-state lighting that yields excellent color rendering. To gain understanding of the photophysical properties and mechanisms for broadband emission, we have constructed a modular fluorescence microscope for ultrasensitive spectroscopy of individual nanoparticles. Using 400-nm wide-field excitation from a frequency-doubled Ti-Sapphire laser and a high-efficiency electron-multiplying CCD, we observe that single CdSe nanocrystals exhibit blinking and abrupt photobleaching, often after detection of only a few hundred photons. Moreover, spectrally dispersed imaging shows that each particle emits the entire broadband spectrum. We discuss mechanisms for homogeneous broadband emission and ongoing experiments in which the instrument is configured for scanning, confocal, two-channel, time-resolved single photon counting for studies of photon antibunching, emission lifetimes, and correlations between spectral regions.

9:36AM A38.00005 Measuring Building Insulation[1] , BETH PARKS, Colgate University — Currently, the only way for homeowners to learn about the effectiveness of their home insulation is to hire an energy auditor. This difficulty deters homeowners from taking action to improve energy efficiency. In principle, measuring the temperature difference between a wall surface and the interior of a home is sufficient to determine the wall insulation, but in practice, temperature cycles from the heating system make a single measurement unreliable. I will describe a simple and inexpensive thermocouple-based device to measure this temperature difference and report results obtained by monitoring this temperature difference over multiple heating cycles in a range of buildings.

[1]Patent application 12/555371

9:48AM A38.00006 Optimized Electronic Transport Measurements in Titanium Oxide , JEFFREY LINDEMUTH, Lake Shore Cryotronics — Titanium Oxide is a material with applications in thermal electric and solar cell applications. Measurement of electronic transport properties by standard methods, for instance Hall effect are made difficult by the low mobility of the material and coupled with the thermal electric properties of the material. Measurements of the resistivity and Hall effect are optimized to reduce the thermal electric effects on the measurement. The Hall measurement is further optimized, by use of AC field Hall method, to obtain reliable mobility values and carrier type determination. Optimization of the measurement includes noise reduction and repeatability of the measurement. Both constant temperature and room temperature measurements are used in the optimization method.

10:00AM A38.00007 Neutron scattering studies of glassy Li^+ superionics , TOM HEITMANN, University of Missouri Research Reactor, LEO ZELLA, New Mexico State University, ALI ZAIDI, Missouri State University, MUNESH RATHORE, ANSHUMAN DALVI, Birla Institute of Technology and Science, SAIBAL MITRA, Missouri State University — Two distinct neutron scattering techniques were implemented in the study of glassy superionic materials composed of a complex network of their interconnected sub-units: Li_2O, $NH_4H_2PO_2$, and Li_2SO_4. The use of disordered materials underlies an effort to promote Li^+ mobility, while suppressing e^- conductivity, which makes them good candidates for use as electrolytes in lithium ion batteries. We present triple-axis spectrometer results of energy resolved vs. energy integrated neutron scattering that indicate the presence of a broad range of dynamic processes in the materials, rather than well-defined excitations. Additionally, we report on neutron diffraction data that demonstrates the formation of crystallites within the material upon annealing up to 450 °C. Such crystallites hinder the performance of the materials as electrolytes, which is evident in thin film devices where heating is unavoidable during fabrication.

10:12AM A38.00008 ABSTRACT WITHDRAWN –

10:24AM A38.00009 Lithiation of UHV-prepared CoO Conversion Battery Materials Studied by XPS and TEM[1] , RYAN THORPE, Rutgers, SYLVIE RANGAN, ROBERT BARTYNSKI, MAHSA SINA, FREDERIC COSANDEY, Rutgers University — Lithium-ion conversion batteries can store 2-3 times more energy than intercalation batteries by fully reducing their constituent divalent or trivalent transition metal compounds during discharge. A prototypical conversion compound is CoO, which follows the reaction $2Li^+ + 2e^- + Co^{(2+)}O \rightarrow 2Li_2O + Co^{(0)}$ upon discharge. However, the cycling stability of conversion electrodes is poor, and capacity losses have prevented their implementation. To study the electronic and morphological changes that occur during the conversion reaction, we have grown 5 nm polycrystalline and epitaxial CoO films and exposed them to atomic Li in UHV to simulate cell discharge. Using XPS to monitor the valence state of Co and film stoichiometry, we find that at 25°C this reaction is inhibited by the formation of a Li_2O_2 overlayer, which is a kinetic barrier for Li diffusion. This is alleviated by heating the film to 150°C, thereby enhancing Li diffusivity through the overlayer and enabling complete reduction of the film. Epitaxial films are reduced with less Li than is required by polycrystalline films, suggesting the presence of channels through which Li is able to diffuse. In both cases, no cobalt phases other than CoO and Co are observed.

10:36AM A38.00010 In situ Measurements of the Solid Electrolyte Interphase in Li-Ion Batteries Using Neutron Reflectometry , JOSEPH DURA, NIST - Center for Neutron Research, JEANETTE OWEJAN, Electrochemical Energy Research Laboratory, General Motors, STEVEN DECALUWE, Dept. of Mechanical Engineering, Colorado School of Mines, JON OWEJAN, Electrochemical Energy Research Laboratory, General Motors — The huge advantages of Li-ion batteries, i.e. high energy density and specific power are due not only to the low mass of Li, but also a direct result of the high operating voltage provided by the large electrochemical potential of Li. However, these advantages come at a cost, as all known electrolytes are unstable at these potentials. Li-ion batteries are only made possible by the solid electrolyte interphase, SEI, a passivation layer that forms from the decomposition products of certain electrolytes. Ideally the SEI offers sufficient electronic resistance when it has grown thick enough to stop additional electrolyte decomposition. However, slow continued SEI growth leads to capacity fade and increased cell resistance. Despite the SEI's critical significance, currently structural characterization is incomplete because of the reactive and delicate nature of the SEI and the electrolyte system in which it forms. Here we present the first in situ neutron reflectometry measurements of the SEI layer as function of potential in a working lithium half-cell. The SEI layer after 10 and 20 CV cycles is 4.0 and 4.5 nm, respectively, growing to 8.9 nm after a series of potentiostatic holds that approximates a charge/discharge cycle. Specified data sets show uniform mixing of SEI components.

10:48AM A38.00011 Low temperature MRFM probe development and initial characterization of organic solar cells , MARK MONTI, DIMITRI ALEXSON, DORAN SMITH, U.S. Army Research Laboratory — We report on the construction of a Magnetic Resonance Force Microscope (MRFM) for organic solar cell characterization. Organic bulk-heterojunction solar cells (OSCs) consist of a blend of two organic semiconductors- an electron donating polymer and an electron accepting fullerene. The efficiency of blended OSCs is highly dependent on the phase separation between the donor and acceptor materials. MRFM offers a unique toolset to study OSCs with the potential to gain insight into the morphology of the buried heterostructure on an actual device. The MRFM probe will operate at 4K and up to 9T using force gradient detection of magnetic resonance via an ultra sensitive single crystal silicon cantilever. We plan on performing NMR spectroscopy on OSCs using a shuttling technique whereby the sample is shuttled far from the gradient magnetic particle during the encoding portion of the NMR RF pulses. We will present on the status of the probe development and on our initial experiments on organic solar cells.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A39 GSCCM DCOMP DMP: Focus Session: Materials in Extremes: Theory and Simulations 348 - Aleksey Kolmogorov, Binghamton University-SUNY

8:00AM A39.00001 Aluminum/water reactions under extreme conditions , JOSEPH HOOPER, Naval Postgraduate School — We discuss mechanisms that may control the reaction of aluminum and water under extreme conditions. We are particularly interested in the high-temperature, high-strain regime where the native oxide layer is destroyed and fresh aluminum is initially in direct contact with liquid or supercritical water. Disparate experimental data over the years have suggested rapid oxidation of aluminum is possible in such situations, but no coherent picture has emerged as to the basic oxidation mechanism or the physical processes that govern the extent of reaction. We present theoretical and computational analysis of traditional metal/water reaction mechanisms that treat diffusion through a dynamic oxide layer or reaction limited by surface kinetics. Diffusion through a fresh solid oxide layer is shown to be far too slow to have any effect on the millisecond timescale (even at high temperatures). Quantum molecular dynamics simulations of liquid Al and water surface reactions show rapid water decomposition at the interface, catalyzed by adjacent water molecules in a Grotthus-like relay mechanism. The surface reaction barriers are far too low for this to be rate-limiting in any way. With these straightforward mechanisms ruled out, we investigate two more complex possibilities for the rate-limiting factor; first, we explore the possibility that newly formed oxide remains a metastable liquid well below its freezing point, allowing for diffusion-limited reactions through the oxide shell but on a much faster timescale. The extent of reaction would then be controlled by the solidification kinetics of alumina. Second, we discuss preliminary analysis on surface erosion and turbulent mixing, which may play a prominent role during hypervelocity penetration of solid aluminum projectiles into water.

8:36AM A39.00002 Development of a Reactive Force Field for Shock-Induced Chemistry in Ti/B Nanocomposite[1] , JASON QUENNEVILLE, Spectral Sciences, Inc. — A ReaxFF reactive force field is under development for describing the physics and chemistry of Ti/B mixtures under shock compression. In this presentation, we will summarize the parameterization of the force field for the reactants and the most stable product of the reaction, TiB_2 in the P6/mmm space group. We will describe the behavior of crystalline TiB_2 under uniaxial and hydrostatic compression and the structure of the crystal with varying void densities as calculated with periodic DFT. In addition, we will compare the results obtained for these properties and others (*e.g.*, lattice constants, elastic constants, bulk modulus) with the newly developed ReaxFF force field. The force field developed in this work for TiB_2 is combined with Ti and B ReaxFF force fields developed previously to yield a force field suitable for describing shock-induced reactions of Ti and B. Preliminary molecular dynamics studies will also be detailed.

8:48AM A39.00003 Rotational defects and plastic deformation in molecular crystal RDX[1] , ANIRBAN PAL, CATALIN PICU, Rensselaer Polytechnic Institute — Defects in molecular crystals differ in many aspects from their atomic counterparts. Molecules in the crystal lattice can undergo conformational changes or twist and rotate into various configurations during deformation. These processes play an important role in the mechanics at a larger scale by controlling critical parameters like dislocation mobility. We present a computational study of such processes in cyclo-trimethylene-trinitramine (RDX), an energetic molecular crystal. Conformational changes, rotational defects and their role in the deformation mechanics of RDX is investigated using molecular dynamics simulations. Structure and mobility of dislocations are also presented and role of conformational and rotational defects in dislocation mobility is discussed.

9:00AM A39.00004 Electronic stopping power from ab-initio Ehrenfest molecular dynamics , ANDRE SCHLEIFE, Lawrence Livermore National Laboratory, YOSUKE KANAI, The University of North Carolina at Chapel Hill, ALFREDO CORREA, Lawrence Livermore National Laboratory — Many materials are exposed to particle radiation: Metal walls of nuclear reactors in fission systems are subject to ion bombardment. Solar cells and semiconductor components in satellites are damaged by ions from cosmic rays. In order to achieve high radiation tolerance, it is essential to comprehend the interaction of fast projectiles with the ionic and electronic system of the target at a fundamental level. Based on the real-time propagation of time-dependent Kohn-Sham equations we developed a highly parallel plane-wave implementation of non-adiabatic Ehrenfest molecular dynamics, overcoming the adiabatic Born-Oppenheimer approximation. Thanks to the excellent scalability of our explicit integration scheme on supercomputers, it allows for the parameter-free computation of electronic stopping with hundreds of atoms in the calculation. We summarize our approach with some attention to important computational details. The influence of different charge states of H, He, and Li projectiles penetrating an Al target will be outlined. While we find good agreement with experiment up to the maximum of electronic stopping, deviations for high velocities are discussed in the light of the theoretical framework and off-channeling effects. Prepared by LLNL under Contract DE-AC52-07NA27344.

9:12AM A39.00005 Simulations of nonequilibrium warm dense gold produced by ultrafast heating , B. HOLST, V. RECOULES, M. TORRENT, CEA, DAM, DIF, Arpajon, France, Z. CHEN, V. SAMETOGLU, Y.Y. TSUI, University of Alberta, Canada, S.E. KIRKWOOD, University of Ottawa, Canada, M. REID, University of Northern British Columbia, Canada, S. MAZEVET, LUTH, Observatoire de Paris, France, A. NG, University of British Columbia, Canada — The interaction of femtosecond laser pulses with metals produces nonequilibrium states consisting of hot electrons and cold ions. These can last for many picoseconds before relaxing to a thermodynamic equilibrium. Recent experiments using a chirped pulse probe technique provided AC conductivity data of gold at a sufficient time resolution to observe this relaxation process. We developed an ab-initio model that characterizes thermodynamic properties of warm dense matter states in nonequilibrium. Our theoretical scheme combines a standard two temperature model with temperature dependent material parameters and an energy transfer rate that are obtained by means of ab-initio simulations. This enables us to give a prediction for the temperature evolution during the relaxation process. Additionally, we derive the AC conductivity of the nonequilibrium states from our simulations using the Kubo-Greenwood formula. It is used to test our model against measurements. We observe agreement with experiment using an energy relaxation rate, that is smaller than predicted, giving us reason to revisit its determination. We can furthermore provide thermodynamical and structural data of nonequilibrium warm dense gold which are not accessible in experiment.

9:24AM A39.00006 Finite-temperature orbital-free GGA molecular dynamics for warm dense hydrogen[1] , VALENTIN KARASIEV, T. SJOSTROM, S.B. TRICKEY, Physics and QTP, Univ. Florida — The computational description of warm dense matter (WDM) by means of a combination of the Kohn-Sham (KS) finite-temperature density functional theory (DFT) for the electrons and classical molecular dynamics (MD) for the ions becomes an intractable task at high T (typically a few hundred kK). Finite-temperature orbital free DFT (OF-DFT) is a less expensive alternative. Only two non-interacting free-energy functionals for OF-DFT had been published and used until recently: the finite-temperature Thomas-Fermi (ftTF) model (Feynman *et al.*, 1949) and ftTF with second-order gradient corrections (ftSGA) (Perrot, 1979). Here we report first results of OF-DFT MD simulations for warm dense H with a pair of newly developed ftGGA free energy functionals [1] for the non-interacting kinetic energy and entropy. The equation of state from these new functionals shows much better agreement with the reference KS MD results than results from the ftTF and ftSGA models. Other issues, *e.g.* convergence of the OF self-consistent procedure, also will be discussed.

9:36AM A39.00007 Temperature Dependence of the Kinetic Energy of the Correlated Electron Plasma by Restricted Path-Integral Molecular Dynamics[1] , KEITH RUNGE, University of Florida, PIERRE DEYMIER, University of Arizona — Recent progress in orbital-free Density Functional Theory (OF-DFT), particularly with regard to temperature dependent functionals, has promise for the simulation of warm dense matter (WDM) systems. WDM includes systems with densities of an order of magnitude beyond ambient or more and temperatures measured in kilokelvin. A challenge for the development of temperature dependent OF-DFT functionals is the lack of benchmark information with temperature and pressure dependence on simple models under WDM conditions. We present an approach to fill this critical gap using the restricted path-integral molecular dynamics (rPIMD) method. Electrons are described as harmonic necklaces within the discrete path integral representation while quantum exchange takes the form of cross linking between electron necklaces. A molecular dynamics algorithm is used to sample phase space and the fermion sign problem is addressed by restricting the density matrix to positive values. The temperature dependence of kinetic energies for the strongly coupled electron plasma is presented for a number of Wigner-Seitz radii in terms of a fourth order Sommerfeld expansion.

[1]Supported by US DoE Grant DE-SC0002139

9:48AM A39.00008 Path Integral Simulations of Heavy, Warm Dense Matter[1] , KEVIN DRIVER, BURKHARD MILITZER, University of California, Berkeley — We develop an all-electron path integral Monte Carlo (PIMC) method for warm dense matter composed of elements with core electrons. For several second- and third-row elements, PIMC pressures, internal energies, and pair-correlation functions compare well with density functional theory molecular dynamics (DFT-MD) at low temperatures and enable the construction of coherent equations of state over a wide range of temperatures and densities. Details of the method and results will be discussed.

[1]Funding provided by the NSF (DMS-1025370). Computational resources provided by the National Center for Atmospheric Research and Lawrence Berkeley National Laboratory.

10:00AM A39.00009 Atomistic and first principles studies of Si nanoparticles under pressure , MARIA CHAN, Argonne National Laboratory, DANIEL HANNAH, Northwestern University, RICHARD SCHALLER, Argonne National Laboratory — In this talk, we will discuss the structural, optical and electronic properties of silicon nanoparticles under high pressure, obtained using a combination of classical molecular dynamics and first principles density functional theory calculations. The results will be corroborated with experimental findings.

10:12AM A39.00010 Anharmonic Phonons in Complex Systems: Application to MgSiO3-Perovskite , DONG-BO ZHANG, TAO SUN, RENATA WENTZCOVITCH, University of Minnesota — We propose a strategy to capture phonon frequency renormalization due to phonon-phonon interactions included in molecular dynamics simulations (self-consistent phonons). This strategy is effective irrespective of crystal structure complexity and facilitates the Fourier interpolation of anharmonic frequencies throughout the Brillouin zone. Calculation of anharmonic frequency shifts in $MgSiO_3$-perovskite validates the method by reproducing well irregular thermal shifts measured by Raman spectroscopy at ambient conditions. *Research supported by NSF/EAR*

10:24AM A39.00011 Phase stability in pulsar and magnetar crusts , TYLER ENGSTROM, VINCENT CRESPI, BENJAMIN OWEN, JAMES BRANNICK, XIAOZHE HU, Penn State — The outermost several hundred meters of a neutron star crust is similar to a white dwarf interior, consisting of nuclei screened by a relativistic, degenerate electron gas. Free neutrons don't appear until a density of 4×10^{11} g/cc. Below a depth of several tens of meters, corresponding to 10^6-10^8 g/cc, the nuclei are thought to crystallize. Unlike white dwarfs, most observed neutron stars have enormous magnetic fields. On the surface of a typical pulsar, the field is $\sim 10^{12}$ gauss, while for magnetars it is several orders of magnitude stronger. Sub-surface fields are likely to be of a similar or greater strength. Quantum ab-initio methods for this regime are still in a state of infancy. In this talk we describe a solution of the nonlinear Thomas-Fermi PDE for completely degenerate, super-strongly magnetized electrons, using a domain decomposition technique with boundary conditions appropriate to close-packed lattices of nuclei. Excited Landau levels are included in the model. Our numerical method makes use of Hypre multigrid-preconditioned solvers. Equation of state and phase diagram calculations will be presented, and implications for astrophysical observations discussed.

10:36AM A39.00012 Magnetic Evolution of the <100> Interstitial Loop Formation Process in bcc Iron[1] , HAIXUAN XU, ROGER STOLLER, G. MALCOLM STOCKS, Oak Ridge National Lab — Interstitial loops are a signature of radiation damage in materials and are only observed in systems far from equilibrium state due to their high formation energies (approximately 4eV). Unlike other bcc metals, in which the interstitial loops are almost exclusively $\frac{1}{2}$ <111> type, two types of loops, <100>and $\frac{1}{2}$ <111> are identified in bcc iron. Although $\frac{1}{2}$ <111> loops can be formed directly by atomic displacment cascades, the mechanism of <100> loop formation had remained undetermined since they were observed fifty years ago. Recently, the formation mechanism has been discovered using self-evolving atomistic kinetic Monte Carlo (SEAKMC) simulations. Here we describe the influence of magnetism in the corresponding loop formation process using the *ab initio* locally self-consistent multiple-scattering (LSMS) method. Significant magnetic moment changes during the loop formation process are observed and their effect on the loop stability are evaluated. In addition, the effects of <100> loop formation on the microstructural evolution and material properties will be discussed.

10:48AM A39.00013 Using numeric simulations to inform experimental data analysis: A new method to account for characteristic bending under dynamic loading and release[1] , SCOTT ALEXANDER, JUSTIN BROWN, Sandia National Laboratories — Dynamic high pressure experiments are often subject to unwanted wave interactions such as reflections from window interfaces or free surfaces where there is an impedance mismatch. In ramp loading experiments or under shock loading of materials resulting in a complex wave structure, these wave interactions can result in changes to the observed wave speeds. This effect, known as characteristic bending, can lead to significant errors in the measured material properties if not properly accounted for. Several approaches exist to correct for characteristic bending, however, they are limited to a one-to-one material response. New methodology has been developed based on control system theory to correct for characteristic bending without this limitation. By comparing simulated *in-situ* and window (or free surface) data, a transfer function is defined which captures the effects due to wave interactions. Application of this function to the experimental data results in *in-situ* profiles free from perturbations due to wave interactions. Experimental data, both with and without strong characteristic bending present, will be presented to illustrate the utility of this new approach.

Session A40 DMP: Focus Session: Collective Diffusion and Self Organization 349 - Michael S. Altman, Hong Kong University of Science and Technology

8:00AM A40.00001 Evidence for Collective Motion in LEEM Measurements of Metals on Semiconductors[1] , SHIRLEY CHIANG, YU SATO[2], JASON GIACOMO[3], CORY MULLET, MARSHALL VAN ZIJLL, BRET STENGER, DYLAN LOVINGER[4], University of California Davis — We review evidence for collective motion from LEEM measurements of three metal on semiconductor systems: Pb/Ge(111), Au/Ge(111), and Ag/Ge(110). Pb/Ge(111) shows a novel phase separation with fluctuating domains of $\sim$ 100nm size which spontaneously switch back and forth from the (1x1) to β phase in the region of the phase diagram where the two phases coexist. This striking mechanism occurs because nm-scale domains can have thermally-induced density fluctuations comparable to the density difference between the two phases (PRL, 99, 096103 (2007)). Au/Ge(111) also shows evidence for fluctuating domains between the ($\sqrt{3}$x$\sqrt{3}$)R30 and (1x1) phases, both for small domains of 100nm diameter, and at the edges of large domains on a sample with low step density. LEEM movies also show "hopping" of large islands (tens to hundreds of nm in diameter) of Au on Ge(111). Self-assembly of large one dimensional (1D) islands (1-10 μm x 70-140 nm, $\sim$ 7nm high, for 7ML) along the [1,-1,0] direction occurs for Ag grown from 300-530 °C on Ge(110). During the growth process, such 1D islands have been observed to collapse into other islands and defects in $<$ 1sec.

8:12AM A40.00002 Super-diffusive Motion of the Pb Wetting Layer on the Si(111) Surface , M.S. ALTMAN, K.L. MAN, M.M.T. LOY, Hong Kong University of Science and Technology, M.C. TRINGIDES, Iowa State University — An unusual mass tansport behavior has been observed in the dense Pb wetting layer on the Si(111) surface. Mass transport is studied by observing non-equilibrium coverage profile evolution with low energy electron microscopy and micro-low energy electron diffraction (m-LEED). The strong sensitivity of diffraction features to Pb coverage in this system allows the Pb coverage profile to be determined precisely with high spatial resolution using m-LEED. Equilibration of an initial coverage step profile produced by laser induced thermal desorption proceeds by the exchange of mass between two steep coverage gradients that travel in opposite directions with invariant shapes. The coverage profile between these two moving edges unexpectedly exhibits a concave shape that apparently contradicts local mass conservation given by the continuity equation. The equilibration time is independent of Pb coverage above a critical coverage, 1.24 ML, but diverges sharply below. The observed spatio-temporal characteristics and lower cutoff for fast dynamics may signal a very unusual coverage dependence of diffusion or might suggest an exceptional collective super-diffusive mechanism by which diffusion is not driven by the local coverage gradient in the usual way.

8:24AM A40.00003 Incorporation-limited growth of molecular film: Zn-phthalocyanine on Ag(100)[1] , JERZY SADOWSKI, ABDULLAH AL-MAHBOOB, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973 — Metal phthalocyanines draw considerable attention due to their potential for energy and environmental applications. However, the control of film fabrication, necessary for achieving optimized performance of organic devices, remains a challenge. Here, we present results of low-energy electron microscopy (LEEM) studies of incorporation-limited growth mechanism of zinc-phthalocyanine (ZnPc) thin films on Ag(100) substrate. We found that when ZnPc is deposited on a substrate kept at lower temperature (RT to 430K), the resulting film has a double domain epitaxial structure, resembling that of bulk ZnPc, with domain sizes in the sub-micrometer range. At above 440K, the film ordering changes into a 5x5 commensurate structure, having only a single crystalline orientation. In situ LEEM of the nucleation and growth of the film allowed us to find a crossover of equilibrium concentration of diffusing molecules versus temperature for both adsorption phases, and thus to tune the type of nucleation. We determined that at favorable growth conditions, the 5x5 phase undergoes a thermodynamic phase transition into the bulk-like structure and we were able to obtain ZnPc bulk-like films with unprecedented quality, with single crystalline domain sizes in the range of millimeters.

8:36AM A40.00004 Modeling Patterning of Heteroepitaxial Overlayers from Nano to Micron Scales , TAPIO ALA-NISSILA, Aalto University School of Science and Brown University — Thin heteroepitaxial overlayers have been proposed as templates to generate stable, self-organized nanostructures at large length scales, with a variety of important technological applications. However, modeling strain-driven self-organization is a formidable challenge due to a large span of length and time scales involved. In this talk, I will present a method for predicting the patterning of ultrathin films on micron length scales with atomic resolution [K.R. Elder *et al.*, Phys. Rev. Lett. **108**, 226102 (2012)]. It is based on the Phase-Field Crystal model, which allows one to reach diffusive time scales for relaxation of the system. We make quantitative predictions for the type of superstructures (stripes, honeycomb, triangular) and length scales of pattern formation of both compressively strained and tensile overlayers on metal-metal systems, including Cu on Ru(0001), Cu on Pd(111), and Ag on Cu(111). Our findings are in excellent agreement with previous experiments and call for future experimental investigations of such systems.

9:12AM A40.00005 Dewetting of Epitaxial Silver Film on Silicon by Thermal Annealing , CHARLOTTE E. SANDERS, The University of Texas, Department of Physics, GARY L. KELLOGG, Sandia National Laboratories, Nanoscale Sciences Department, C.-K. SHIH, The University of Texas, Department of Physics — It has been shown that noble metals can grow epitaxially on semiconducting and insulating substrates, despite being a non-wetting system: low temperature deposition followed by room temperature annealing leads to atomically flat film morphology. However, the resulting metastable films are vulnerable to dewetting, which has limited their utility for applications under ambient conditions. The physics of this dewetting is of great interest but little explored. We report on an investigation of the dewetting of epitaxial Ag(111) films on Si(111) and (100). Low energy electron microscopy (LEEM) shows intriguing evolution in film morphology and crystallinity, even at temperatures below 100°C. On the basis of these findings, we can begin to draw compelling inferences about film-substrate interaction and the kinetics of dewetting. Financial support is from NSF, DGE-0549417 and DMR-0906025. This work was performed, in part, at the Center for Integrated Nanotechnologies, User Facility operated for the U.S. DOE Office of Science. Sandia National Lab is managed and operated by Sandia Corp., a subsidiary of Lockheed Martin Corp., for the U.S. DOE's National Nuclear Security Administration under DE-AC04-94AL85000.

9:24AM A40.00006 Dewetting of nanometer-sized thin films on a solid substrate: A large-scale simulation study , TRUNG NGUYEN, MIGUEL FUENTES-CABRERA, JASON FOWLKES, Oak Ridge National Laboratory, Oak Ridge, Tennessee, USA, JAVIER DIEZ, ALEJANDRO GONZALEZ, Universidad Nacional del Centro de la Provincia de Buenos Aires, Tandil, Argentina, LOU KONDIC, New Jersey Institute of Technology, Newark, New Jersey, United States, W. MICHAEL BROWN, Oak Ridge National Laboratory, Oak Ridge, Tennessee, USA, PHILIP RACK, University of Tennessee, Knoxville — Directing the assembly of nanoparticles into ordered arrays using interfacial instability has been of practical interest. Recent experimental and theoretical studies have revealed the role of the Raleigh-Plateau instability in determining the breakup process of fluidic thin films deposited on a solid substrate. Using all-atom models, we investigate the dynamic behavior of nanometer-sized thin rings as a function of initial geometry in the presence of Raleigh-Plateau-type instability and inward pressure due to initial azimuthal curvature. We consider systems at close-to-experiment scales consisting of hundreds of thousands to millions of atoms using LAMMPS, a massively parallel molecular dynamics package, with GPU acceleration. The simulation results are shown to be consistent with continuum modeling calculations in predicting the fastest growth mode and breakup times, both of which are important to the evolution of the thin films. Our study serves to stimulate future investigations connecting experimental and theoretical findings towards fabricating ordered arrays of nanoparticles.

9:36AM A40.00007 Fe on graphene: interaction, growth morphology, and thermal stability , XIAOJIE LIU, Beijing Computational Scientific Research Center, Beijing, 100084, People's Republic of China, CAI-ZHUANG WANG, MYRON HUPALO, Ames Laboratory-US Department of Energy, and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, 50011, USA, HAI-QING LIN, Beijing Computational Scientific Research Center, Beijing, 100084, People's Republic of China, KAI-MING HO, MICHAEL TRINGIDES, Ames Laboratory-US Department of Energy, and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, 50011, USA — The nucleation and growth of Fe on graphene is highly unusual. Constantly increasing in island density with coverage is observed by experiment which indicates the presence of strong adatom predominantly repulsive interactions. We study Fe adatoms interactions on graphene by first-principles calculations and showed that the interactions between Fe adatoms consist of a short-range attraction and long-range repulsions. By investigating the adsorption energies and diffusion barriers for Fe adatoms on graphene, we also predict that Fe on graphene exhibit a three-dimensional growth mode. Fe nanostructures on graphene are also shown be stable against aggregation. The predictions from first-principles calculations are consistent with experimental observations.

9:48AM A40.00008 Distribution of Steps with Finite-Range Interactions: Analytic Approximations and Numerical Results , DIEGO LUIS GONZÁLEZ, Univ. del Valle, Cali, Colombia, DIEGO FELIPE JARAMILLO, GABRIEL TÉLLEZ, Univ. de Los Andes, Bogotá, Colombia, T.L. EINSTEIN[1], Physics and CMTC, Univ. Maryland, College Park — While most Monte Carlo simulations assume only nearest-neighbor steps interact elastically, most analytic frameworks (especially the generalized Wigner distribution) posit that each step elastically repels all others. In addition to the elastic repulsions, we allow for possible surface-state-mediated interactions. We investigate analytically and numerically how next-nearest neighbor (NNN) interactions and, more generally, interactions out to q'th nearest neighbor alter the form of the terrace-width distribution and of pair correlation functions (i.e. the sum over n'th neighbor distribution functions, which we investigated recently.[2] For physically plausible interactions, we find modest changes when NNN interactions are included and generally negligible changes when more distant interactions are allowed. We discuss methods for extracting from simulated experimental data the characteristic scale-setting terms in assumed potential forms.

10:00AM A40.00009 Developments in Characterizing Capture Zone Distributions in Island Growth , T.L. EINSTEIN[1], Physics & CMTC, Univ. Maryland, College Park, ALBERTO PIMPINELLI, Rice Quantum Institute, Rice Univ., DIEGO LUIS GONZÁLEZ, Univ. del Valle, Cali, Colombia, RAJESH SATHIYANARAYANAN, IBM Semiconductor R&D, Bangalore, India — The utility of using the distribution of capture zones (CZD) to characterize epitaxial growth continues to mount. For non-Poisson deposition (i.e. when island nucleation is not fully random) the areas of these Voronoi cells (proximity polygons) can be well described by the generalized Wigner distribution (GWD), particularly in the central region around the mean area. We discuss several recent applications to experimental systems, showing how this perspective leads to insights about the critical nucleus size. In contrast, several studies have shown that the GWD may not describe the numerical data from painstaking simulations in both tails. We discuss some refinements that have been proposed. Finally, we comment on applications to social phenomena such as area distributions of secondary administrative units (like counties) and of Voronoi cells around Metro stops.

10:12AM A40.00010 Magicity of Transition Metal Nanoclusters Based on Generalized Wulff Construction , SHUNFANG LI, XINGJU ZHAO, School of Physics and Engineering, Zhengzhou University, Zhengzhou, Henan 450001, China, X.S. XU, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei, Anhui 230026, China, Y.F. GAO, Department of Materials Science and Engineering, University of Tennessee, Knoxville, TN, ZHENYU ZHANG, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei, Anhui 230026, China — Nanoclusters with extra stability at certain cluster sizes are known as magic clusters which may exhibit exotic properties. Two dominant mechanisms have been invoked to define the magicity: electronic shell closure for simple and noble metal clusters, and atomic shell closure for rare-gas and other clusters. The latter mechanism is inherently rooted in the classic Wulff construction, which stipulates that the preferred structure of a cluster should minimize its total surface energy, resulting in close-shelled icosahedronal transition metal (TM) clusters with magic sizes of 13, 55, and 147. Here we use TM clusters around 55 as examples to demonstrate that the Wulff construction must be generalized to also include the contribution of edge atoms. Specifically, a majority of the TM_{55} clusters are found to be fcc or hcp crystal fragments with much fewer edge atoms than the icosahedrons, and the magic number is shifted to its nearby even numbers. The generalized Wullf construction established here should be instrumental in fabricating nanoclusers with desirable functionalities.

10:24AM A40.00011 Magicity of Ag nanoclusters on Si(111)-(7×7) by atomic manipulation , FANGFEI MING, The Chinese University of Hong Kong, GUOHUA ZHONG, Shenzhen Institute of Advanced Technology, Chinese Academy of Science, Shenzhen, KEDONG WANG, The Chinese University of Hong Kong, ZHENYU ZHANG, ICQD, Hefei National Laboratory for Physical Sciences at Microscales, University of Science and Technology of China, XUDONG XIAO, The Chinese University of Hong Kong and Shenzhen Institute of Advanced Technology, Chinese Academy of Science, Shenzhen — Nanoclusters with extra stability at certain cluster sizes are known as magic clusters, whose magicity depends sensitively on the environments. Using scanning tunneling microscopy and first-principles calculations, we explore the dynamics and magicity of Agn (n=1-26) clusters constructed atom-by-atom on a Si(111)-(7×7) surface. By measuring the thermal stability of clusters of increasing size, a set of magic clusters are distinctly established, which in return helps to reveal the preferred growth sequence towards geometrically close-shelled Ag10 and Ag25 clusters with extra inertness. We further use a probing atom to demonstrate that the adatom-cluster interaction is highly anisotropic, preserving the attractive nature of an Ag-Ag bond at short distances, but becoming repulsive at large distances mediated by the substrate. These innovative findings of fundamental importance are also expected to be significant in surface catalytic reactions and related technological areas.

10:36AM A40.00012 Atomic Force Microscopy of Vertically Stacked Focused-Ion-Beam Induced Quantum Dots , MARTA LUENGO-KOVAC, TIMOTHY SAUCER, Department of Physics, University of Michigan, ANDREW MARTIN, JOANNA MILLUNCHICK, Department of Materials Science and Engineering, University of Michigan, VANESSA SIH, Department of Physics, University of Michigan — Control over the positioning of semiconductor quantum dots (QDs) could facilitate the coupling of QDs to photonic crystal cavities and has applications in the development of high-efficiency solar cells. QDs grown through self-assembly nucleate at random spatial locations. However, a focused ion beam (FIB) can be used to create preferential sites for QD nucleation, and this pattern can be transferred to subsequent layers of QDs, either due to strain or residual effects of the templating. Multilayer QD stacks can therefore maintain the lateral pattern of the initial layer while separating QDs from material damage induced by the patterning. Multilayer QD structures were grown on FIB-patterned GaAs(001) substrates with 10 nm thick GaAs spacers between the layers. The substrates were patterned with sixteen square arrays of holes with spacings of 0.25, 0.5, 1.0, and 2.0 μm each at FIB dwell times of 1.0, 3.0, 6.0, and 9.0 ms. We report on the effects of multilayer QD growth on the initial layers through atomic force microscope (AFM) imaging of single, two-, and three-layer FIB-templated QD samples.

10:48AM A40.00013 Kinetic Monte-Carlo Simulation of Substrate Vacancy Diffusion in C_{60} on Ag(111) , JOSEPH DULNY III, SANGZI LIANG, JOHN GROH, JORGE SOFO, RENEE DIEHL, The Pennsylvania State University — Recently, clean Ag(111) surfaces with monolayer C_{60} adsorbates have been studied with scanning tunneling microscopy and low energy electron diffraction. These studies revealed that the C_{60} forms a commensurate $(2\sqrt{3}\times 2\sqrt{3})R30^\circ$ phase on the Ag(111) substrate and when observed with STM, the C_{60} molecules appear either "bright" or "dim." LEED studies showed that these two species of C_{60} are a result of the C_{60} taking two different orientations on the Ag substrate, one of which only occurs when the C_{60} is located over an Ag lattice vacancy. STM also shows the bright and dim C_{60} molecules change location over time. This "flipping" behavior implies that vacancy diffusion in the Ag lattice is taking place. Here, using the kinetic Monte-Carlo algorithm, we model the diffusion of vacancies in the Ag lattice. Data collected from simulations is compared to experimental data on the flipping rate of the C_{60} vs. temperature and the bright/dim C_{60} ratio vs. temperature. Our model tells us that intralayer vacancy diffusion is taking place and that adsorption of C_{60} on Ag(111) results in vacancy creation in the Ag(111) surface. Additional density functional theory calculations support the conclusions of the model.

Monday, March 18, 2013 8:00AM - 10:24AM –

Session A41 DAMOP: Localization, Cooling, Trapping and Clocks 350 - Matthew Beeler, University of Maryland

8:00AM A41.00001 Theory of interaction-induced localization for mobile impurities[1] , JIAN LI, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA, JIN AN, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China, CHIN-SEN TING, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA, TEXAS CENTER FOR SUPERCONDUCTIVITY TEAM — A phenomenological model is proposed for the interaction-induced localization of mobile impurities in the cold atomic systems. The fundamental properties of the transition between the extended and localized impurity state in one, two and three dimension are investigated with this model. We find that the transition is continuous in one and two dimension while discontinuous in three dimension. We show that the dynamics of single localized impurity is described by a soliton and predict the formation of bipolaron and Wigner lattices for many fermionic impurities. Our theory explains the essential features from specific models in a unified picture and can be used to realize several exotic phenomena with ultracold impurity atoms.

8:12AM A41.00002 Single parameter scaling for 1d systems with scale-free long-range correlated disordered potentials[1] , NANCY SANDLER, GREG PETERSEN, Ohio University — Disordered optical lattices have renewed the interest in localization physics under power-law long-range correlated disorder potentials. For these systems, insight can be gained by combining numerical data and analytic expressions based on scaling laws. Thus, the absence of a transition in short-range correlated disordered systems can been proved by verifying the validity of the single parameter scaling (SPS) hypothesis for the distribution function of the dimensionless conductance. In this talk we discuss this hypothesis for a system with scale-free long-range correlated disorder potentials of the form $\sim 1/r^\alpha$ as a function of the correlation exponent α. We present results for the 1^{st} (the β-function) and 2^{nd} (variance) cumulants of the distribution function, and show a violation of SPS at an energy scale E_{SPS}, that scales with an α-renormalized disorder strength. Calculations for the localization length reveals the existence of a crossover scale E_{cross} between two regions as correlations increase. An increased number of more extended-like states appear near the band-center while states near the band edges experience reduced localization lengths. We confirm previously predicted scaling behavior near the band edge and center.

8:24AM A41.00003 Anderson localization of pairs in bichromatic optical lattices , GIULIANO ORSO, GABRIEL DUFOUR, Laboratoire Materiaux et Phenomenes Quantiques, University Paris Diderot and CNRS, France — We investigate the formation of bound states made of two interacting atoms moving in a one dimensional quasi-periodic optical lattice. We derive the quantum phase diagram for Anderson localization of both attractively and repulsively bound pairs. We calculate the pair binding energy and show analytically that its behavior as a function of the interaction strength depends crucially on the nature -extended, multifractal, localized- of the single-particle atomic states. Experimental implications of our results are discussed. Reference: Phys. Rev. Lett. 109, 155306 (2012)

8:36AM A41.00004 Many-body energy localization transition in periodically driven system , LUCA D'ALESSIO, ANATOLI POLKOVNIKOV, Boston University — According to the second law of thermodynamics the total entropy and energy of a system is increased during almost any dynamical process. Notable exceptions are known in noninteracting systems of particles moving in periodic potentials. Here the phenomenon of dynamical localization can prevent heating beyond certain threshold. However, it was believed that driven ergodic systems will always heat without bound. Here, on the contrary, we report strong evidence of dynamical localization transition in periodically driven ergodic systems in the thermodynamic limit. This phenomenon is reminiscent of many-body localization in energy space. We report numerical evidence based on exact diagonalization of small spin chains and theoretical arguments based on the Magnus expansion. Our findings are valid for both classical and quantum systems.

8:48AM A41.00005 Many-Body Localization in a Quasiperiodic System , SHANKAR IYER, GIL REFAEL, California Institute of Technology, VADIM OGANESYAN, College of Staten Island, City University of New York, DAVID HUSE, Princeton University — Recent theoretical and numerical evidence suggests that localization can survive the introduction of interactions in disordered many-body systems, giving rise to a so-called many-body localization transition. This dynamical phase transition is relevant to questions of thermalization in quantum systems. It separates a many-body localized phase, in which localization prevents thermalization, from an "ergodic" phase in which the usual assumptions of quantum statistical mechanics hold. Here, we present numerical evidence that many-body localization also occurs in models that omit true disorder in favor of a quasiperiodic potential. In one dimension, these systems already have a single-particle localization transition, and we show that this transition becomes a many-body localization transition upon the introduction of interactions. These issues are increasingly experimentally relevant, because quasiperiodic potentials have been used in place of true disorder in recent experiments with cold atoms and with photonic waveguides.

9:00AM A41.00006 Dynamic Localization of Interacting Particles in an Anharmonic Potential , MARK HERRERA, THOMAS ANTONSEN, EDWARD OTT, University of Maryland, SHMUEL FISHMAN, Technion-Israel Institute of Technology — We investigate the effect of anharmonicity and interactions on the dynamics of an initially Gaussian wavepacket in a weakly anharmonic potential. We note that depending on the strength and sign of interactions and anharmonicity, the quantum state can be either localized or delocalized in the potential. We formulate a classical model of this phenomenon and compare it to quantum simulations done for a self consistent potential given by the Gross-Pitaevskii Equation.

9:12AM A41.00007 Anderson Localization of a non-interacting Bose-Einstein condensate with effective spin-orbit interaction in a quasiperiodic optical lattice[1] , LU ZHOU, Department of Physics, East China Normal University, HAN PU, Department of Physics and Astronomy, Rice University, WEIPING ZHANG, Department of Physics, East China Normal University — We theoretically investigate the localization properties of a noninteracting atomic Bose-Einstein condensate moving in a one-dimensional quasiperiodic optical lattice potential in the tight-binding regime. The atoms are subject to effective spin-orbit coupling induced by external laser fields. We present the phase diagram in the parameter space of the disorder strength and those related to the effective spin-orbit coupling. The phase diagram are verified via multifractal analysis of the atomic wavefunctions. We found that spin-orbit coupling can lead to the spectra mixing (coexistence of extended and localized states) and the appearance of mobility edges.

[1]We acknowledge National Natural Science Foundation of China under Grant No 11004057, Shanghai Rising-Star Program under Grant No. 12QA1401000 and the "Chen Guang" project under Grant No 10CG24 for financial supports.

9:24AM A41.00008 Laser Controlled Rotational Cooling in Na_2 Based on Exceptional Points[1] , ADAM WEARNE, VIATCHESLAV KOKOOULINE, University of Central Florida, OSMAN ATABEK, ROLAND LEFEBVRE, Laboratoire de Photophysique Moleculaire du CNRS, Universite Paris-Sud, Orsay, France, UCF-ISMO COLLABORATION — In this study, we describe a computational simulation of the interaction of diatomic molecule with an applied laser field. It is known that for certain laser wavelengths and intensities, the wave functions and eigenenergies of two states become degenerate. Such locations in the laser parameter space are known as "exceptional points." By applying a laser pulse which encircles one or more exceptional points in the parametric plane of wave length versus intensity, one can bring an ensemble of diatomic molecule into a pre-selected rovibrational state after the laser pulse is over. During this process, a fraction of the molecules dissociate, and those which remain, are brought to the chosen rovibrational state. Although this scheme can be applied more generally, here we use Na_2 as an illustrative example. We examine the locations in the parameteric space of exceptional points, which lead to the exchange of rotational states, and how the shape of laser pulse in the parametric plane affects the "purification" of the chosen rovibrational state and the dissociation of other states.

[1]This work is supported by the National Science Foundation, Grant No PHY-08-55622

9:36AM A41.00009 Dynamic dimer formation between superionic fluorines in CaF_2 , MASASHI SAITO, TOMOFUMI TASAKA, KAZUO TSUMURAYA, Meiji University, Kanagawa, Japan — Recently we have elucidated the formation of the dynamic dimers in the conductor α-CuI through the analyses of the correlation peaks of the partial pair-distribution functions and the partial angle distribution functions with the first principles molecular dynamics (MD) method.(J. Phys. Soc. Jpn. 81,055603(2012).) The present study investigate the formation of the dynamic dimers and the migration paths of the dimers in the conductor CaF_2 with the MD method. The fluorines form the dynamic $32f$-$8c$ dimers with the coordinate (x,x,x) x=0.300. These incommensurate dimers allow to decrease the migration barriers of the fluorines.

9:48AM A41.00010 Laser cooling of Iron atoms , THIERRY BASTIN, NICOLAS HUET, STEPHANIE KRINS, Univ de Liege — We report on the first laser cooling of Iron atoms. Our laser cooling setup makes use of 2 UV laser radiation sent colinearly in a 0.8 m Zeeman slower. One laser is meant for optical pumping of the Iron atoms from the ground state to the lowest energy metastable state. The second laser cools down the atoms using a quasi-perfect closed transition from the optical pumped metastable state. The velocity distribution at the exit of the Zeeman slower is obtained from a probe laser crossing the atom beam at an angle of 50 degrees. The fluorescence light is detected using a photomultiplier tube coupled with a boxcar analyzer. The Iron atom beam is produced with a commercial effusion cell working at around 1950 K. Our laser radiations are stabilized using standard saturated-absorption signals in both an Iron hollow cathode absorption cell and an Iodine cell. We will present our experimental setup, as well as the first evidences of cooled down Iron atoms at the exit of the Zeeman slower.

10:00AM A41.00011 Ytterbium in quantum gases and atomic clocks: van der Waals interactions and blackbody shifts , S. G. PORSEV, M. S. SAFRONOVA, University of Delaware, CHARLES W. CLARK, Joint Quantum Institute — We evaluated the C_6 coefficients of Yb-Yb and Yb-alkali/group II van der Waals interactions with 2% uncertainty. The only existing results for such quantities are for the Yb-Yb dimer. Our value, $C_6 = 1929(39)$ a.u., is in excellent agreement with the recent experimental determination of 1932(35) a.u. [M. Kitagawa, *et al., Phys. Rev. A* **77**, 012719 (2008)]. We have also developed a new approach for the calculation of the dynamic correction to the blackbody radiation shift. We have calculated this quantity for the Yb $6s^2\ {}^1\mathrm{S}_0 - 6s6p\ {}^3\mathrm{P}^\circ_0$ clock transition with 3.5% uncertainty. This reduces the fractional uncertainty due to the blackbody radiation shift in the Yb optical clock at 300 K to the 10^{-18} level. For further details, see http://arxiv.org/abs/1208.1456

10:12AM A41.00012 Blackbody radiation shift in the Sr optical atomic clock , M.S. SAFRONOVA, S.G. PORSEV, University of Delaware, U.I. SAFRONOVA, University of Nevada, Reno, M.G. KOZLOV, Petersburg Nuclear Physics Institute, CHARLES W. CLARK, Joint Quantum Institute — We evaluated the static and dynamic polarizabilities of the $5s^2\ ^1\mathrm{S}_0$ and $5s5p\ ^3\mathrm{P}_0^\circ$ states of Sr using the high-precision relativistic configuration interaction + all-order method. Our calculation explains the discrepancy between the recent experimental $5s^2\ ^1\mathrm{S}_0$ - $5s5p\ ^3\mathrm{P}_0^\circ$ dc Stark shift measurement = 247.374(7) a.u. [T. Middelmann, S. Falke, C. Lisdat and U. Sterr, arXiv:1208.2848 (2012)] and the earlier theoretical result of 261(4) a.u. [S. G. Porsev and A. Derevianko, *Phys. Rev. A* **74**, 020502(R) (2006)]. Our present value of 247.5 a.u. is in excellent agreement with the experimental result. We also evaluated the dynamic correction to the BBR shift with 1% uncertainty; -0.1492(16) Hz. The dynamic correction to the BBR shift is unusually large in the case of Sr (7%) and it enters significantly into the uncertainty budget of the Sr optical lattice clock. We suggest future experiments that could further reduce the present uncertainties. For further information, see http://arxiv.org/abs/1210.7272

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A42 FIAP: Integer Quantum Hall Effect Hilton Baltimore Holiday Ballroom 3 - James Tse, University of Texas

8:00AM A42.00001 Study of the correlation between microwave reflection and microwave-induced magnetoresistance oscillations in the GaAs/AlGaAs two dimensional electron system , TIANYU YE, R.G. MANI, Georgia State University, W. WEGSCHEIDER, ETH-Zurich — High frequency microwave illumination produces oscillatory magneto-resistance in the high mobility two dimensional electron systems (2DES) at liquid helium temperatures, in a perpendicular magnetic field. Present theories for this phenomenon include the displacement model and the inelastic model, which have hardly perfectly simulated- or predicted- experimental results such as, for example, the linear microwave polarization dependence of this effect [1]. Besides the usual direct electrical measurement on the 2DES samples, we have examined the microwave reflection to remotely sense the electron-transport in the 2DES, in order to better understand the physical contributions. Here, we compare the concurrently observed direct transport and remotely sensed reflection from the high mobility GaAs/AlGaAs samples under various microwave illumination conditions. Correlated changes between the two types of measurements are reported.

[1] R. G. Mani et al., Phys. Rev. B 84, 085308 (2011); A. N. Ramanayaka et al., Phys. Rev. B 85, 205315 (2012); and references therein.

8:12AM A42.00002 Study of the phase-shift in the linear-polarization-angle-dependence of the microwave radiation-induced magnetoresistance oscillations in the GaAs/AlGaAs system , HAN-CHUN LIU, TIANYU YE, R. G. MANI, Department of Physics and Astronomy, Georgia State University, Atlanta, Georgia 30303, USA, W. WEGSCHEIDER, Laboratorium fur Festkorperphysik, ETH Zurich, 8093 Zurich, Switzerland — Microwave- and terahertz-induced magneto-resistance oscillations (MTIMRO) in the two-dimensional electron system have been a topic of interest since the observation of photo-excited zero-resistance states in the GaAs/AlGaAs system. Some theoretical developments in this area have been based on the premise of linear-polarization-insensitivity of MTIMRO. Recent studies using new experimental methods have shown, however, a strong linear polarization sensitivity of MTIMRO.[1,2] In addition, Ramanayaka *et al.*[2] have observed that the phase shift θ_0, which is a parameter in a fitting formula to sinusoidal variation of diagonal resistance, R_{xx}, with polarization angle, θ, as $R_{xx}(\theta) = A \pm C\cos^2(\theta\text{-}\theta_0)$, depends upon radiation frequency f, magnetic field B, and sign of B.[2] Here, we investigate the dependence of the phase shift θ_0 in the linear-polarization-angle-dependence upon the above-mentioned experimental variables. In particular, we examine the relationship between f and θ_0. The results will be compared with theory.[3,4] [1] R. G. Mani *et al.*, Phys. Rev. B 84, 085308 (2011). [2] A. N. Ramanayaka *et al.*, Phys. Rev. B 85, 205315 (2012). [3] J. Inarrea, Appl. Phys. Lett. 100, 242103 (2012). [4] X. L. Lei and S. Y. Liu, Phys. Rev. B 86, 205303 (2012). Work has been supported by DOE DE-SC0001762.

8:24AM A42.00003 Nonlinear conductance of highly mobile 2D electrons in Corbino geometry[1] , SEAN BYRNES, SCOTT DIETRICH, Graduate Center, CUNY, New York, NY 10016 USA, SERGEY VITKALOV, Physics Department, City College of the City University of New York, New York 10031, USA, D. V. DMITRIEV, I. V MARCHISHIN, A. A. BYKOV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — Current induced oscillations of differential conductivity of two-dimension electrons, placed in quantizing magnetic fields, are observed in GaAs quantum wells in Corbino geometry. The conductance oscillations are described by Zener tunneling between Landau orbits in the absence of the Hall electric field[1]. An electronic state with zero-differential conductance is found in nonlinear response to an electric field E applied to two dimensional Corbino discs of highly mobile carriers. The state occurs above a critical electric field $E > E_{th}$ at low temperatures and is accompanied by an abrupt dip in the differential conductance. The proposed model consider local instability of the electric field E as the origin of the observed phenomenon. [1] A.A Bykov, D.V. Dmitriev, I.V.Marchishin, S.Byrnes, S.A.Vitkalov, Appl. Phys. Lett.100, 251602 (2012)

8:36AM A42.00004 Quantum oscillations of nonlinear response in electron systems with variable density[1] , SCOTT DIETRICH, SEAN BYRNES, Graduate Center at the City University of New York, SERGEY VITKALOV, City College of New York, D.V. DMITRIEV, A.V. GORAN, A.A. BYKOV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — Oscillations of dissipative resistance of two-dimensional electrons in GaAs quantum wells are observed in response to an electric current and a strong magnetic field applied perpendicular to the two-dimensional systems. The period of the current-induced oscillations does not depend on the magnetic field and temperature. At a fixed current the oscillations are periodic in inverse magnetic fields with a period that does not depend on dc bias. Oscillations were also studied in GaAs quantum wells with variable two dimensional electron density. At a fixed magnetic field the period of the current induced oscillations depends linearly on the electron density. Both results corroborate the recently proposed model that considers the DC bias-induced spatial re-population of Landau levels as the origin of the resistance oscillations.

8:48AM A42.00005 Inter-subband resistance oscillations in crossed electric and magnetic fields[1] , SERGEY VITKALOV, SCOTT DIETRICH, SEAN BYRNES, Physics Department, City College of the City University of New York, New York 10031, USA, A.V. GORAN, A.A. BYKOV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — Quantum oscillations of nonlinear resistance are investigated in response to electric current and magnetic field applied perpendicular to single GaAs quantum wells with two populated sub-bands. At small magnetic fields current-induced oscillations appear as Landau-Zener transitions between Landau levels inside the lowest sub-band. The period of these oscillations is proportional to the magnetic field. At high magnetic fields, a different kind of quantum oscillations emerges with a period that is independent of the magnetic field. At a fixed current the oscillations are periodic in inverse magnetic field with a period that is independent of the dc bias. The proposed model considers these oscillations as a result of spatial variations of the energy separation between two sub-bands induced by the electric current (Scott Dietrich, Sean Byrnes, Sergey Vitkalov, A. V. Goran, and A. A. Bykov Phys. Rev. B 86, 075471).

9:00AM A42.00006 Nonlinear transport in two-dimensional electron systems with separated Landau levels[1]

MAXIM KHODAS, Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, MICHAEL ZUDOV, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544 — The resistivity of a high mobility two-dimensional electron gas subject to a weak perpendicular magnetic field and low temperatures is strongly non-linear. This nonlinearity becomes more pronounced when the Landau level width becomes smaller than the cyclotron energy; at very small dc electric fields the differential resistivity becomes strongly suppressed and can even approach zero. Using the quantum kinetics approach we calculate the characteristic current responsible for the suppression and compare the results to the experimental data obtained in a high mobility 2DES at low temperatures.

9:12AM A42.00007 Microwave-induced resistance oscillations at low temperatures[1]

PETER MARTIN, MICHAEL ZUDOV, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, JOHN WATSON, MICHAEL MANFRA, Department of Physics, Purdue University, West Lafayette, Indiana 47907, JOHN RENO, Sandia National Laboratories, Albuquerque, New Mexico 87185, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544 — At low temperatures, the amplitude of microwave-induced resistance oscillations in two dimensional electron systems is predicted to scale as $1/T^2$. In contrast to this prediction, our experiments shows that the amplitude tends to saturate at low temperatures, even in the regime of very low microwave intensities. In this talk we will discuss radiation-induced heating as a possible source of the observed saturation and ways to estimate actual temperature of irradiated 2D electrons.

9:24AM A42.00008 Anomalies in nonlinear transport of two-dimensional electron gas[1]

QUENTIN EBNER, MICHAEL ZUDOV, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544 — When a dc current is passed through a high-mobility two-dimensional electron system subject to a weak magnetic field, its differential resistivity exhibits periodic oscillations as a function of applied current. The waveform of these oscillations, known as Hall field-induced resistance oscillations, is well established both experimentally and theoretically. In this talk we will present experimental data which show dramatic deviations of the oscillation waveform from the theoretically predicted.

[1]The work at Minnesota was supported by the DOE Grant DE-SC0002567. The work at Princeton was partially funded by the Gordon and Betty Moore Foundation and by the NSF MRSEC Program through the Princeton Center for Complex Materials (DMR-0819860).

9:36AM A42.00009 Microwave-induced resistance oscillations in tilted magnetic fields[1]

ALEX BOGAN, SERGEI STUDENIKIN, ANDY SACHRAJDA, National Research Council of Canada, Ottawa, Ontario K1A 0R6, Canada, ANTHONY HATKE, MICHAEL ZUDOV, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA — We have studied the effect of an in-plane magnetic field on microwave-induced resistance oscillations in a high mobility two-dimensional electron system. We have found that the oscillation amplitude decays exponentially with an in-plane component of the magnetic field. While these findings cannot be accounted for by existing theories, our analysis suggests that the decay can be explained by a quadratic-in-parallel-field correction to the quantum scattering rate.

[1]The work at Minnesota was supported by the DOE Grant DE-SC0002567. The work at Princeton was partially funded by the Gordon and Betty Moore Foundation and by the NSF MRSEC Program through the Princeton Center for Complex Materials (DMR-0819860).

9:48AM A42.00010 Effective mass from microwave photoresistance in high-mobility 2D electron systems[1]

MICHAEL ZUDOV, ANTHONY HATKE, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, JOHN WATSON, MICHAEL MANFRA, Department of Physics, Purdue University, West Lafayette, Indiana 47907, USA, LOREN PFEIFFER, KENNETH WEST, Princeton University, Department of Electrical Engineering, Princeton, New Jersey 08544, USA — We have performed microwave photoresistance measurements in high mobility GaAs/AlGaAs quantum wells and investigated the value of the effective mass. Surprisingly, the effective mass, obtained from the period of microwave-induced resistance oscillations, is found to be considerably lower than the band mass in GaAs. This finding provides evidence for electron-electron interactions which can be probed by microwave photoresistance in very high Landau levels. In contrast, the measured magneto-plasmon dispersion revealed an effective mass which is close to the band mass, in accord with previous studies.

10:00AM A42.00011 Pinning modes of solid phases in wide quantum wells near $\nu = 1$

ANTHONY HATKE, BRENDEN MAGILL, NHMFL, YANG LIU, Princeton University, LLOYD ENGEL, NHMFL, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KURT BALDWIN, Princeton University — Near filling factor $\nu = 1$ the microwave spectra of sufficiently low disorder two-dimensional electron systems (2DESs) exhibit a resonance [1], understood as a Wigner solid pinning mode, in which quasiparticles or quasiholes oscillate about their pinned positions. For 2DESs in a wide quantum well of thickness 54 nm and density n=2.4 x 10^{11} cm^{-2}, we find that the resonance frequency, f_{pk}, is comparatively enhanced for ν<0.88, and interpret this as a phase transition between Wigner solids, as shown by the reentrant integer quantum Hall effect (RIQHE) recently observed in wide wells under similar conditions [2]. As n is increased by gating, the transition to enhanced f_{pk} moves closer to $\nu = 1$, similar to the RIQHE in [2]. [1] Chen et al., Phys. Rev. Lett. **91**,016801 (2003). [2] Liu et al., Phys. Rev. Lett. **109**, 036801 (2012).

10:12AM A42.00012 Effects of short-ranged disorder on pinning modes of 2D electron system near $\nu = 1$

B.H. MOON, B.A. MAGILL, L.W. ENGEL, NHMFL/FSU, Tallahassee, USA, D.C. TSUI, L.N. PFEIFFER, K.W. WEST, Princeton University, Princeton, USA — We performed microwave measurements on 2-D electron systems (2DES) in heterostructures of $Al_xGa_{1-x}As$/ $Al_{0.3}Ga_{0.7}As$ in which the 2DES resides in dilute Al alloy, with x=0.21, 0.33 and 0.85%. The dilute Al atoms are randomly distributed [1]. Around Landau filling $\nu = 1$,the samples exhibit microwave resonances which differ from pinning mode resonances observed [2] near $\nu = 1$ in unalloyed samples. The alloyed samples have larger resonance frequencies, and resonances that exist over wider ranges of ν, extending to $|\nu\text{-}1| \sim 0.2$. Also in the disordered samples, the resonances are not quasiparticle-quasihole symmetric around $\nu = 1$, and there is strong frequency and ν dependence in the spectra away from rational fractional ν, down to 0.6.

[1] W. Li *et al.*, *Appl.Phys. Lett.* **83**, 2832 (2003).

10:24AM A42.00013 Probing the lowest Landau level energy of the light hole subband in wide quantum wells , SUKRET HASDEMIR, YANG LIU, MANSOUR SHAYEGAN, Dept. Electrical Engineering, Princeton University, ROLAND WINKLER, Department of Physics, Northern Illinois University, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Dept. Electrical Engineering, Princeton University — In two-dimensional hole systems (2DHSs) with finite thickness, the degeneracies of the heavy hole (HH) and light hole (LH) states are lifted. The HH-LH anti-crossing and mixing lead to non-parabolic 2D dispersion relations, especially for the LH subbands, invalidating the simple effective-mass approximation for 2DHSs. We study the magneto-resistance of 2DHSs confined to symmetric, wide GaAs quantum wells, where the second subband (LH1) is occupied. From the magnetic field (B) and densities where the lowest Landau level of the LH1 subband crosses the Landau levels of HH1 subband, we can extrapolate the cyclotron energy of the LH1 subband, which decreases with increasing B at low fields, and increases at high field. This peculiar behavior reveals that the cyclotron mass for the LH1 subband is negative at small magnetic fields, but becomes positive at high magnetic field, consistent with theoretical simulations.

10:36AM A42.00014 Determining the Location of Charged Background Impurities in High Mobility AlGaAs/GaAs 2DEG Structures , JERRY LEE, KIRK BALDWIN, KEN WEST, LOREN PFEIFFER, Princeton University — The two main Coulomb scattering contributions to the scattering rate $1/\tau$ in the modulation-doped AlGaAs/GaAs two-dimensional electron gas (2DEG) system are scattering from unintentional background charged impurities present in the GaAs and AlGaAs materials, and scattering by the intentional dopants in the doped layer. Theoretical studies [1] indicate that for structures dominated by scattering from unintentional background charged impurities in the conducting channel, a carrier mobility μ versus 2DEG density n relationship of $\mu \approx n^{0.8}$ is anticipated. On the other hand, in structures where the dominant scattering mechanism is due to charged impurities or dopants in the nearby AlGaAs barriers, a relationship of $\mu \approx n^{1.8}$ is expected. Using high-mobility heterostructure insulated-gate field-effect transistors (HIGFETs) fabricated by molecular beam epitaxy (MBE) and lithography, we demonstrate a technique for determining the location of the mobility limiting charged impurities. We intentionally introduce charged impurities into either the barrier or the quantum well of our HIGFETs and measure the slope of μ versus n. We find a dependence of $\mu \approx n^{0.7}$ when the dopants are inserted into the quantum well. In contrast, we measure a dependence of $\mu \approx n^{1.8}$ when impurities are introduced into the barrier. Our results are in excellent agreement with theoretical predictions and pave the way towards utilizing these relationships to diagnose the exact location of impurities in high-mobility structures for FQHE applications. [1] A. Gold, Appl. Phys. Lett. **54**, 2100 (1989).

10:48AM A42.00015 Monitoring Excitations of the N=1 Landau Level by Optical Emission at mK Temperatures[1] , ANTONIO LEVY, URSULA WURSTBAUER, DOV FIELDS, ARON PINCZUK, Columbia University, JOHN WATSON, SUMIT MONDAL, MICHAEL J. MANFRA, Purdue University, KEN W. WEST, LOREN N. PFEIFFER, Princeton University — Optical emission experiments have proven to be powerful contactless probe of collective states of electrons in the second (N=1) Landau Level (LL) [1,2]. We report the emission spectrum from optical recombination in the N=0 and N=1 LL's the second LL. The 2DEG is confined in ultra-high-mobility GaAs quantum well structures. Optical emission red-shifted from the main luminescence of the N=0 and N=1 LL are interpreted as shakeup processes of quasiparticles in the N=1 LL. Results of two samples with different carrier densities measured in the temperature range of 42mK$\leq$T$\leq$650mK will be compared. The experimental observations will be discussed taking into account the striking quantum phases dominating the second LL. [1] Manfra, M. J. et al. Phys. Rev. B 57, R9467 (1998) [2] Gravier, L. et al. Phys. Rev. Lett. 80, 3344 (1998).

Session A43 DCP: Focus Session: Multiscale modeling–Coarse-graining in Space and Time I

Hilton Baltimore Holiday Ballroom 2 - William Noid, Pennsylvania State University

8:00AM A43.00001 The Theory of Ultra Coarse-graining , GREGORY VOTH, University of Chicago — Coarse-grained (CG) models provide a computationally efficient means to study biomolecular and other soft matter processes involving large numbers of atoms correlated over distance scales of many covalent bond lengths and long time scales. Variational methods based on information from simulations of finer-grained (e.g., all-atom) models, for example the multiscale coarse-graining (MS-CG) and relative entropy minimization methods, provide attractive tools for the systematic development of CG models. However, these methods have important drawbacks when used in the "ultra coarse-grained" (UCG) regime, e.g., at a resolution level coarser or much coarser than one amino acid residue per effective CG particle in proteins. This is due to the possible existece of multiple metastable states "within" the CG sites for a given UCG model configuration. In this talk I will describe systematic variational UCG methods specifically designed to CG entire protein domains and subdomains into single effective CG particles. This is accomplished by augmenting existing effective particle CG schemes to allow for discrete state transitions and configuration-dependent resolution. Additionally, certain conclusions of this work connect back to single-state force matching and open up new avenues for method development in that area. These results provide a formal statistical mechanical basis for UCG methods related to force matching and relative entropy CG methods and suggest practical algorithms for constructing optimal approximate UCG models from fine-grained simulation data.

8:36AM A43.00002 Coarse-graining with information theory and the relative entropy , M. SCOTT SHELL, University of California Santa Barbara — There remain many both fundamental and practical/methodological questions regarding how coarse-grained models should be developed. Are there theoretically intuitive and numerically robust strategies for turning small-scale all-atom simulations into coarse models suitable for large-scale modeling? How can we identify what atomic details are unnecessary and can be discarded? Are there systematic ways to detect emergent physics? Here we discuss a fundamentally new approach to this problem. We propose that a natural way of viewing the coarse-graining problem is in terms of information theory. A quantity called the relative entropy measures the information lost upon coarse graining and hence the (inverse) fitness of a particular coarse-grained model. Minimization of the relative entropy thus provides a sort-of universal variational principle for coarse-graining, and a way to "automatically" discover and generate coarse models of many systems. We show that this new approach enables us to develop very simple but surprisingly accurate models of water, hydrophobic interactions, self-assembling peptides, and proteins that enable new physical insights as well as simulations of large-scale interactions. We discuss both theoretical and numerical aspects of this approach, in particular highlighting a new coarse-graining algorithm that efficiently optimizes coarse-grained models with even thousands of free parameters. We also discuss how the relative entropy approach suggests novel strategies for predicting the errors of coarse models, for identifying relevant degrees of freedom to retain, and for understanding the relationships among other coarse-graining methodologies.

9:12AM A43.00003 A Top Down Approach to Multiscale Modeling of Structured Materials , JUAN DE PABLO, University of Chicago, Institute for Molecular Engineering — There is considerable interest in developing multiscale modeling approaches capable of describing both the structure and dynamics of inhomogeneous materials having characteristic features ranging from a few to a several hundred nanometers. Examples include block polymers, which exhibit an array of ordered morphologies with characteristic dimensions in the tens of nanometers, or liquid crystalline materials, where ordered domains and defects can also span tens of nanometers. This presentation will describe a relatively new class of particle-based methods that rely on established continuum models to describe thermodynamic properties, but that adopt a molecular representation to describe molecular structure and mesoscale morphology. While these methods can describe mesoscale structure quantitatively, they can also be augmented to describe the dynamics of complex fluids, including entangled polymers, composites, and nanoparticle dispersed in structured fluids, over dynamic ranges that in some cases span multiple orders of magnitude.

9:48AM A43.00004 Coarse graining approach to First principles modeling of structural materials , KHORGOLKHUU ODBADRAKH, DON NICHOLSON, AURELIAN RUSANU, GERMAN SAMOLYUK, ORNL, YANG WANG, Pittsburgh Supercomputing Center, ROGER STOLLER, XIAOGUANG ZHANG, GEORGE STOCKS, ORNL — Classical Molecular Dynamic (MD) simulations characterizing extended defects typically require millions of atoms. First principles calculations employed to understand these defect systems at an electronic level cannot, and should not deal with such large numbers of atoms. We present an efficient coarse graining (CG) approach to calculate local electronic properties of large MD-generated structures from the first principles. We used the Locally Self-consistent Multiple Scattering (LSMS) method for two types of iron defect structures 1) screw-dislocation dipoles and 2) radiation cascades. The multiple scattering equations are solved at fewer sites using the CG. The atomic positions were determined by MD with an embedded atom force field. The local moments in the neighborhood of the defect cores are calculated with first-principles based on full local structure information, while atoms in the rest of the system are modeled by representative atoms with approximated properties. This CG approach reduces computational costs significantly and makes large-scale structures amenable to first principles study. Work is sponsored by the USDoE, Office of Basic Energy Sciences, "Center for Defect Physics," an Energy Frontier Research Center. This research used resources of the Oak Ridge Leadership Computing Facility at the ORNL, which is supported by the Office of Science of the USDoE under Contract No. DE-AC05-00OR22725.

10:00AM A43.00005 Construction of interaction models of dissipative particle dynamics by coarse-graining Lennard-Jones fluids: Evaluation of non-Markovian formulation , YUTA YOSHIMOTO, TOSHIKI MIMA, The University of Tokyo, AKINORI FUKUSHIMA, Tohoku University, IKUYA KINEFUCHI, The University of Tokyo, TAKASHI TOKUMASU, Tohoku University, SHU TAKAGI, YOICHIRO MATSUMOTO, The University of Tokyo — The application of molecular dynamics (MD) simulation to mesoscale (10-100 nm) flow analysis is computationally expensive at present. Dissipative particle dynamics (DPD) simulation is a powerful candidate for the alternative method because the DPD interaction, which has a soft potential between mesoscopic particles, enables larger space and longer time simulation. In the present study, we develop the method of bottom-up construction of non-Markovian DPD (NMDPD) models by means of MD simulations. We focus on the center of mass of the cluster containing Lennard-Jones particles, and extract the effective forces exerted on the clusters. Moreover, we sample the spectra of fluctuating forces acted on the clusters in the MD system, and find that the white noise used in the conventional DPD simulations should be replaced by colored noise. In order to reproduce the spectra, finite impulse response filters are employed in NMDPD simulations. Finally we evaluate the NMDPD models by comparing the simulation results with the MD counterparts.

10:12AM A43.00006 Solvation free energies of aqueous mixtures in a "truly" open boundary simulation , DEBASHISH MUKHERJI, KURT KREMER, Max-Planck Institute for Polymer Research — (Bio)macromolecular solvation in water cosolvent mixtures are dictated by the preferential interaction of cosolvents with the proteins. The numerical studies in the field are limited to the closed boundary schemes, which, however, suffers from severe system size effects. More specifically, when the conformational transitions are intimately linked to the large concentration fluctuations, the excess of cosolvents near a protein lead to depletion elsewhere in a small-sized closed boundary setup. This disturbs solvent equilibrium within the bulk solution. Therefore, by combining the adaptive resolution scheme (AdResS) with a metropolis particle exchange criterion, we propose a "truly" open boundary method that heals the particle depletion in a closed boundary setup. In AdResS, an all-atom region, containing protein, is coupled to a coarse-grained (CG) reservoir. Particle exchange is performed in the CG region, which otherwise would be impossible in an all-atom setup of dense fluids. We calculate solvation free energies within the all-atom region using Kirkwood-Buff theory. Our method produces well converged solvation energies that are impossible in a brute force all-atom MD of small system sizes. We will discuss two cases of triglycine in aqueous urea and PNIPAm in aqueous methanol.

10:24AM A43.00007 Coarse-Grained Modeling of Mixtures of Charged Macroions[1] , JUN KYUNG CHUNG, ALAN R. DENTON, Department of Physics, North Dakota State University — In suspensions of charged macroions, such as charge-stabilized colloids and polyelectrolyte microgels, the electrostatic interactions between macroions are relatively easily controlled by changing the sizes and charges of the macroions, as well as the concentration of salt. This tunability of interactions can be exploited to stabilize various structures that self-assemble under appropriate conditions. In this talk, a statistical mechanical coarse-graining approach to modeling effective electrostatic interactions in mixtures of charged spherical macroions will be discussed. Taking effective interactions as input, we perform molecular dynamics simulations to calculate pair distribution functions of binary mixtures of charged colloids. For highly charged macroions, incorporating charge renormalization is found to be important. Using thermodynamic perturbation theory, we also analyze phase behavior and explore the possibility of a demixing instability as a function of size and charge asymmetry.

[1]This work was supported by the National Science Foundation under Grant No. DMR-1106331

10:36AM A43.00008 Coarse-Grained Modeling of Colloid-Nanoparticle Mixtures[1] , ALAN R. DENTON, JUN KYUNG CHUNG, Department of Physics, North Dakota State University — Colloid-nanoparticle mixtures have attracted much recent attention for their rich phase behavior. The potential to independently vary size and charge ratios greatly expands the possibilities for tuning interparticle interactions and stabilizing unusual phases. Experiments have begun to explore the self-assembly and stability of colloid-nanoparticle mixtures, which are characterized by extreme size and charge asymmetries. In modeling such complex soft materials, coarse-grained methods often prove essential to surmount computational challenges posed by multiple length and time scales. We describe a hierarchical approach to modeling effective interactions in ultra-polydisperse mixtures. Using a sequential coarse-graining procedure, we show that a mixture of charged colloids and nanoparticles can be mapped onto a one-component model of pseudo-colloids interacting via a Yukawa effective pair potential and a one-body volume energy, which contributes to the free energy of the system. Nanoparticles are found to enhance electrostatic screening and to modify the volume energy. Taking the effective interactions as input to simulations and perturbation theory, we calculate structural properties and explore phase stability of highly asymmetric charged colloid-nanoparticle mixtures.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A44 DBIO GSNP: Focus Session: Population and Evolutionary Dynamics I Hilton Baltimore Holiday Ballroom 1 - Michel Pleimling, Virginia Tech

8:00AM A44.00001 Evolutionary dynamics in finite populations , CHRISTOPH HAUERT, University of British Columbia — Traditionally, evolutionary dynamics has been studied based on infinite populations and deterministic frameworks such as the replicator equation. Only more recently the focus has shifted to the stochastic dynamics arising in finite populations. Over the past years new concepts have been developed to describe such dynamics and has lead to interesting results that arise from the stochastic, microscopic updates, which drive the evolutionary process. Here we discuss a transparent link between the dynamics in finite and infinite populations. The focus on microscopic processes reveals interesting insights into (sometimes implicit) assumptions in terms of biological interactions that provide the basis for deterministic frameworks and the replicator equation in particular. More specifically, we demonstrate that stochastic differential equations can provide an efficient approach to model evolutionary dynamics in finite populations and we use the rock-scissors-paper game with mutations as an example. For sufficiently large populations the agreement with individual based simulations is excellent, with the interesting caveat that mutation events may not be too rare. In the absence of mutations, the excellent agreement extends to small population sizes.

8:36AM A44.00002 Neutral species domination on different lattices for the symmetric stochastic cyclic competition of four species[1] , BEN INTOY, Virginia Tech, SVEN DOROSZ, University of Luxembourg, MICHEL PLEIMLING, Virginia Tech — Although the mean-field solution for four species in cyclic competition is generally in good agreement with stochastic results, it fails to describe the extinction and absorbing states that finite size systems inevitably fall into. We study the effects of dimension, lattice type, and swapping rate between particles on the time it takes for the system to go into a static absorbing state, which consists of a neutral species pair. Lattice types discussed are the well mixed environment, the one-dimensional chain, the Sierpinski triangle, and the two-dimensional square lattice. Data presented were acquired with simulations that have around the order of a thousand lattice sites or less, to capture finite size effects. The formation of domains composed of neutral species yields long lived states which promote coexistence.

[1]This work is supported by the US National Science Foundation through grants DMR-0904999 and DMR-1205309.

8:48AM A44.00003 Biodiversity and co-existence of competing species[1] , AHMED ROMAN, Virginia Tech, DEBANJAN DASGUPTA, University of Virginia, MICHEL PLEIMLING, Virginia Tech — Understanding why and how species co-exist is a necessary step to the program of manipulating multispecies environments in order to preserve the biodiversity of the environment of interest. To this end we consider a generalization of the cyclic competition of species model. We show that our model enjoys a Z_n symmetry which is explained via a simple graph theoretic technique. This symmetry gives rise to pattern formation and cluster coarsening of the species. We show that biodiversity is achievable in the mean field limit provided that the species in the clusters have reaction rates which correspond to non-trivial equilibria.

[1]This work is supported by the US National Science Foundation through grants DMR-0904999 and DMR-1205309.

9:00AM A44.00004 Population oscillations in stochastic Lotka–Volterra models: field theory and perturbational analysis , UWE C. TÄUBER, Department of Physics, Virginia Tech — Field theory tools are applied to analytically study fluctuation and correlation effects in spatially extended stochastic predator-prey systems. In the mean-field rate equation approximation, the classic Lotka–Volterra model is characterized by neutral cycles in phase space, describing undamped oscillations for both predator and prey populations. In contrast, Monte Carlo simulations for stochastic two-species predator-prey reaction systems on regular lattices display complex spatio-temporal structures associated with persistent erratic population oscillations. The Doi–Peliti path integral representation of the master equation for stochastic particle interaction models is utilized to arrive at a field theory action for spatial Lotka–Volterra models in the continuum limit. In the species coexistence phase, a perturbation expansion with respect to the nonlinear predation rate is employed to demonstrate that spatial degrees of freedom and stochastic noise induce instabilities toward structure formation, and to compute the fluctuation corrections for the oscillation frequency and diffusion coefficient. The drastic downward renormalization of the frequency and the enhanced diffusivity are in excellent qualitative agreement with Monte Carlo simulation data.

9:12AM A44.00005 Patterns and Oscillations in Reaction-Diffusion Systems with Intrinsic Fluctuations , MICHAEL GIVER, DANIEL GOLDSTEIN, BULBUL CHAKRABORTY, Brandeis University — Intrinsic or demographic noise has been shown to play an important role in the dynamics of a variety of systems including predator-prey populations, biochemical reactions within cells, and oscillatory chemical reaction systems, and is known to give rise to oscillations and pattern formation well outside the parameter range predicted by standard mean-field analysis. Initially motivated by an experimental model of cells and tissues where the cells are represented by chemical reagents isolated in emulsion droplets, we study the stochastic Brusselator, a simple activator-inhibitor chemical reaction model. Our work extends the results of recent studies on the zero and one dimensional systems with the ultimate goals of understanding the role of noise in spatially structured systems and engineering novel patterns and attractors induced by fluctuations. In the zero dimensional system, we observe a noise induced switching between small and large amplitude oscillations when a separation of time scales is present, while the spatially extended system displays a similar switching between a stationary Turing pattern and uniform oscillations.

9:24AM A44.00006 Flow-driven instabilities during aggregation and pattern formation of Dictyostelium Discoideum: Experiments and modeling , AZAM GHOLAMI, Max-Planck Institute of Dynamics and Self-Organization, Goettingen, Germany., OLIVER STEINBOCK, Department of Chemistry and Biochemistry, Florida State University, Tallahassee, FL, USA., VLADIMIR ZYKOV, EBERHARD BODENSCHATZ, Max-Planck Institute of Dynamics and Self-Organization, Goettingen, Germany. — We report the first experimental verification of the Differential Flow Induced Chemical Instability (DIFICI) in a signaling chemotactic biological population, where a differential flow induces traveling waves in the signaling pattern. The traveling wave speed was observed to be proportional to the flow velocity while the wave period was 7 min, which is comparable to that of starved Dictyostelium cells. Analysis and numerical simulations of the Goldbeter model show that the resulting DIFICI wave patterns appear in the oscillatory regime. In the experiments, we observe that the DIFICI wave pattern disappears after 4-5 h of starvation. We extrapolated the Goldbeter model to the experimental situation. This suggests that the dynamics switches from the oscillatory to the excitable regime as the DIFICI waves disappear in the experiment.

9:36AM A44.00007 Statistical Thermodynamics of Populations , THEMIS MATSOUKAS, Pennsylvania State University — Suppose a population of M individuals forms N groups such that group i contains n_i individuals. Form all possible partitions of M into N and select distributions from this ensemble with selection bias $W[\{n_i\}]$, where W is a functional of distribution $\{n_i\}$. We develop the thermodynamics of this ensemble and its most probable distribution for arbitrary bias W. We obtain the temperature of the ensemble and its relationship to the microcanonical and canonical partition functions; and (ii) show that, depending on the bias functional W, the population may exhibit the equivalent of a phase transition, manifested as the coexistence of two distinct subpopulations in equilibrium with each other. We apply this theory to binary clustering with special interest in conditions that result in the emergence of a single dominant group that overtakes all smaller coexisting groups when the number of groups N is decreased. We show the emergence of the dominant group represents a formal phase transition that is governed by the maximization of the free energy of the ensemble. We provide closed analytical solutions for the special case that the merging probability between two groups is proportional to the product of the number of members in each group.

9:48AM A44.00008 Predictability of evolution in complex fitness landscapes[1] , JOACHIM KRUG, Institute for Theoretical Physics, University of Cologne, Germany — Evolutionary adaptations arise from an intricate interplay of deterministic selective forces and random reproductive or mutational events, and the relative roles of these two types of influences is the subject of a long-standing controversy. In general, the predictability of adaptive trajectories is governed by the genetic constraints imposed by the structure of the underlying fitness landscape as well as by the supply rate and effect size of beneficial mutations. On the level of single mutational steps, evolutionary predictability depends primarily on the distribution of fitness effects, with heavy-tailed distributions giving rise to highly predictable behavior [1]. The genetic constraints imposed by the fitness landscape can be quantified through the statistical properties of accessible mutational pathways along which fitness increases monotonically. I will report on recent progress in the understanding of evolutionary accessibility in model landscapes and compare the predictions of the models to empirical data [2,3]. Finally, I will describe extensive Wright-Fisher-type simulations of asexual adaptation on an empirical fitness landscape [4]. By quantifying predictability through the entropies of the distributions of evolutionary trajectories and endpoints we show that, contrary to common wisdom, the predictability of evolution depends non-monotonically on population size.

10:24AM A44.00009 A Condition for Cooperation in a Game on Complex Networks , TOMOHIKO KONNO, Princeton University — We study a condition of favoring cooperation in a Prisoner's Dilemma game on complex networks. There are two kinds of players: cooperators and defectors. Cooperators pay a benefit b to their neighbors at a cost c, whereas defectors only receive a benefit. The game is a death-birth process with weak selection. Although it has been widely thought that $b/c > \langle k \rangle$ is a condition of favoring cooperation [2], we find that $b/c > \langle k_{\rm nn} \rangle$ is the condition. We also show that among three representative networks, namely, regular, random, and scale-free, a regular network favors cooperation the most, whereas a scale-free network favors cooperation the least. In an ideal scale-free network, cooperation is never realized. Whether or not the scale-free network and network heterogeneity favor cooperation depends on the details of the game, although it is occasionally believed that these favor cooperation irrespective of the game structure.

10:36AM A44.00010 Evolution of regulatory complexes: a many-body system , ARMITA NOUEMOHAMMAD[1], Lewis-Sigler Institute, Princeton University, MICHAEL LAESSIG[2], Institute for theoretical Physics, University of Cologne — In eukaryotes, many genes have complex regulatory input, which is encoded by multiple transcription factor binding sites linked to a common function. Interactions between transcription factors and site complexes on DNA control the production of protein in cells. Here, we present a quantitative evolutionary analysis of binding site complexes in yeast. We show that these complexes have a joint binding phenotype, which is under substantial stabilizing selection and is well conserved within Saccharomyces paradoxus populations and between three species of Saccharomyces. At the same time, individual low-affinity sites evolve near-neutrally and show considerable affinity variation even within one population. Thus, functionality of and selection on regulatory complexes emerge from the entire cloud of sites, but cannot be pinned down to individual sites. Our method is based on a biophysical model, which determines site occupancies and establishes a joint affinity phenotype for binding site complexes. We infer a fitness landscape depending on this phenotype using yeast whole-genome polymorphism data and a new method of quantitative trait analysis. Our fitness landscape predicts the amount of binding phenotype conservation, as well as ubiquitous compensatory changes between sites in the cloud. Our results open a new avenue to understand the regulatory "grammar" of eukaryotic genomes based on quantitative evolution models.

10:48AM A44.00011 Inference of fitness from genealogical trees , MARIJA VUCELJA, Courant Institute of Mathematical Sciences, NYU, ADEL DAYARIAN, BORIS SHRAIMAN, Kavli Institute of Theoretical Physics, UCSB — Natural populations are fitness diverse and can have numerous genes under selection. The genealogical trees, that one obtains by sampling, often bear hallmarks of selection, such multiple mergers, asymmetric tree branches and long terminal branches (the trees are squished towards the root). These are qualitative differences compared to trees in the absence of selection. We propose a theoretical model that links the morphology of a tree with the fitness of the leaves. We obtain multipoint correlation functions of the fitness along the tree. In this way we are able extract some quantitative information about the strength of selection from data-reconstructed trees. The extensions of this approach can potentially be useful for inferring relative fitness of sequenced genomes of tumors and for predicting viral outbreaks.

Session A45 DBIO DPOLY: Focus Session: Structure and Dynamics of Biomembranes I Hilton Baltimore Holiday Ballroom 4 - Fredrick Heberle, Oak Ridge National Laboratory

8:00AM A45.00001 Molecular simulation studies of edges in bilayers and bicelles[1] , JAMES KINDT, Emory University, Department of Chemistry — The instability of the free edge of a lipid bilayer can be quantified by a line tension, or excess free energy per unit length of the edge. Atomistic simulations of bilayer ribbons composed of a series of lipids with varying tail lengths and degrees of saturation have been performed to determine line tensions, with the goal of relating edge stability to structural and elastic properties of the bilayer. Line tensions are relevant to the mechanical stability of bilayer membranes, and can be reduced or eliminated by the inclusion of edge-stabilizing molecules (edge-actants) to the bilayer system. Mixtures of long- and short-tailed phospholipids are known to form aggregates known as "bicelles" that contain bilayers with stable edges. Simulations of "bicelle" mixtures using coarse-grained and atomistic lipid models have been performed to study the partitioning of short-tailed lipids towards the edge and the flexibility of the stabilized edge. Input from these simulations has been used in the development of simple thermodynamic models to rationalize some aspects of bicelle aggregate morphology.

[1]This work was supported by NSF grant CHE-0911285.

8:36AM A45.00002 Shear-induced alignment of "bicellar" phospholipid membranes[1] , MU-PING NIEH, Institute of Materials Science, Chemical, Materials & Biomolcuar Engineering Department, University of Connecticut, MING LI, Institute of Materials Science, Polymer Program, University of Connecticut, NORBERT KUCERKA, Canadian Neutron Beam Centre, National Research Council — "Bicellar" phospholipid mixtures, composed of two types of lipids (i.e., long-chain and short-chain lipids), self-assemble into a magnetically alignable bilayered structure. As a result, the model membranes have been used as membrane substrates for the structural study on membrane-associated proteins in many nuclear magnetic resonance experiments. In this presentation, I will demonstrate the shear-alignability of the bicellar model membranes through an in-situ neutron diffraction study under shear flows, the important controlling parameters and their applications and biological implications.

8:48AM A45.00003 Estimation of Structural Properties Of The Thermally Fluctuated Membrane Based on The Small-Angle Neutron Scattering Data , TAKUMI HAWA, VICTOR LEE, The University of Oklahoma — SANS (Small-angle neutron scattering) and SAXS (Small-angle X-ray scattering) experiments are one of the most important laboratory techniques to determine nanoscale structure of biological and nanotechnology-related systems. These experimental techniques provide extensive information due to the sensitivity of about 1-1000 nm and 2-25 nm length scales for SANS and SAXS, respectively. Recently, the author and his collaborator, Dr. Nagao, studied swollen lamellar structure systems consisting of nonionic surfactant, water, and oil using SANS/NSE (Neutron Spin Echo) and MD (molecular dynamics) simulation. They proposed a new experimental technique to measure the thickness fluctuations of surfactant layers and verified their approach using MD simulations. In this talk we derive a simple mathematical model to estimate the thickness of the membrane as well as the amplitude and the wavelength of the surfactant layers in the membrane. The model is developed based on the harmonic motion of the surfactant layers. We consider both bending and thickness fluctuation motions of the membrane. The membrane thickness estimated from the proposed approach showed an excellent agreement with the SANS experimental results available in the literatures.

9:00AM A45.00004 Lipid bilayer dynamics: Effects of segregation between DMPC and DSPC , MICHIHIRO NAGAO, NIST and Indiana University, PAUL BUTLER, NIST and University of Delaware, ANDREA WOODKA, United States Military Academy, RANA ASHKAR, NIST and University of Maryland — Dynamics in lipid bilayers are believed to play a key role in membrane stabilization. During the past decade, neutron spin echo (NSE) has been used to study the bending elastic behavior of large unilamellar vesicles (radius of around 50 nm). These results reveal that above Tm, where the lipid tails display liquid ordering, the bending modulus is on the order of 10 kT. Below Tm, the value increases by more than an order of magnitude. Recently NSE revealed thickness fluctuations of lipid bilayers above Tm, while none are discernable below Tm. The estimated amplitude of the observed membrane thickness fluctuations is approximately 4 angstroms and the time scale of the motion is on the order of 100 ns. In the present research, structure and dynamics of mixed lipid between dimyristoylphosphatidylcholine (DMPC) and distearoylphosphatidylcholine (DSPC) were investigated using small-angle neutron scattering (SANS) and NSE. DSPC has a higher Tm than DMPC. The mixed lipid systems show segregation between domains in the temperature range between Tm of DMPC and DSPC. The SANS and NSE measurements were performed with changing temperature from above to below the Tm of DSPC. The result indicates a slow down of thickness fluctuations once the segregation takes place.

9:12AM A45.00005 X-ray reflectivity study of a DPPC floating bilayer: Effect of Ca^{2+} ions and temperature , SAMBHUNATH BERA, Northern Illinois University, SAJAL GHOSH, YICONG MA, University of California-San Diego, CURT DECARO, Northern Illinois University, ZHANG JIANG, Advanced Photon Source, LAURENCE LURIO, Northern Illinois University, SUNIL SINHA, University of California-San Diego — We have used a floating bilayer of DPPC (1,2- dipalmitoyl-sn-glycero-3-phosphocholine) to examine the effects on Ca^{++} ion concentration on membrane fluctuations. The density profile of the double bilayer system normal to the support was measured via x-ray specular reflectivity. We find an increase in membrane spacing with ion concentration which we attribute to Ca^{++} ions preferentially binding to the head group of the bilayer. We also find an increase in interfacial roughness which we attribute to the Ca^{++} ions causing a reduction in the layer's bending modulus. These effects are studied as a function of temperature up to the temperature at which the bilayer if found to unbind from the support.

9:24AM A45.00006 Deposition of Homogeneous Single-supported DMPG Lipid Membranes onto a Silica Substrate for Quasielastic Neutron Scattering Experiments[1] , ANDREW MISKOWIEC, MIA BROWN, JASON COOLEY, RENEE JIJI, HASKELL TAUB, JUSTIN GRAYER, GAVIN KING, University of Missouri - Columbia, HELMUT KAISER, University of Missouri Research Reactor, FLEMMING HANSEN, Technical University of Denmark, MADHUSUDAN TYAGI, NIST Center for Neutron Research — We report deposition of single bilayers of dimyristoyl-phosphoglycerol (DMPG) lipid onto a SiO_2-coated Si(100) substrate. These anionic membranes have large-scale homogeneity comparable to that achieved with single-supported uncharged DMPC membranes used for neutron scattering studies.[2] Optimum deposition conditions were found by systematically varying the lipid concentration and both the monovalent and divalent buffer salt concentrations. Plausible mechanisms for the bilayer stability will be discussed. In addition, we report Atomic Force Microscopy measurements of the membrane thickness as a function of temperature near the gel-to-fluid phase transition. We also report initial results of elastic neutron intensity scans vs. temperature taken on the backscattering spectrometer at NIST that probe the freezing of the membrane-associated water for comparison with results obtained with the neutral membrane DMPC.[3]

9:36AM A45.00007 Mobility of water and selected atoms in DMPG lipid bilayer membranes[1] , F.Y. HANSEN, A. ROENNEST, G.H. PETERS, Tech. U. of Denmark, H. TAUB, A. MISKOWIEC, U. Mo. — Molecular dynamics simulations have been used to study the structure and mobility of water and selected atoms in dimyristoyl-phosphoglycerol (DMPG) lipids forming a fully hydrated free standing bilayer membrane at 310 K. The effect of the anionic headgroup in DMPG on structure and dynamics has been studied by comparison with simulation[2] and experimental[3] results for bilayer membranes of dimyristoyl-phosphorylcholine (DMPC) lipids, which have a neutral head group and the same aliphatic tails. The membrane is found to be in the fluid phase with monovalent sodium counter ions and in the gel phase with divalent calcium counter ions as evidenced by an area/lipid change and the NMR order parameter. The simulation results are compared with preliminary neutron scattering results.

9:48AM A45.00008 High-speed Membrane Imaging with Digital Holography , THOMAS DIMIDUK, AMY CHEN, LAURA ARRIAGA, VINOTHAN MANOHARAN, Harvard — Lipid membranes can change on timescales faster than traditional three dimensional imaging tools can follow. Digital holography offers a the potential to observe observe membranes in 3D at 1000 Hz or greater to resolve dynamics down to thermal fluctuations. This works because holography encodes 3D information into a single 2D image, allowing imaging limited only by camera speed. However, precise quantitative interpretation of holograms has proved challenging for samples of any complexity. To address this limitation, I am developing methods based on the discrete dipole approximation and a new mathematical approach to solving inverse problems. I will present these methods and preliminary measurements of membrane dynamics using holography.

10:00AM A45.00009 Compositional interface dynamics within symmetric and asymmetric planar lipid bilayer membranes[1] , TAO HAN, MIKKO HAATAJA, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton NJ 08544 — Compositional domains within multicomponent lipid bilayer membranes are believed to facilitate many important cellular processes. In this work, we will first develop a general model of planar lipid bilayer membrane within a phase field framework, which includes not only advective and diffusive lipid transport mechanism, but also incorporates an asymmetry between the lipid compositions and thermodynamic behavior between the two leaflets, as well as an intermonolayer thermodynamic coupling and friction effects. Then, we will derive the general equations that describe the dynamics of compositional domains within planar membranes with asymmetry in leaflet properties and in the presence of a thermodynamic coupling between the leaflets. These equations are then employed to develop analytical solutions to the dynamics of the recurrence of registration for circular domains in the case of weak coupling. The validity of the analytical solutions is established by a direct comparison between the predicted dynamics and those obtained from numerical simulations of the the phase-field model.

10:12AM A45.00010 The effects of cholesterol concentration in lipid packing and domain registration in ternary mixture lipid multilayer[1] , YICONG MA, SAJAL GHOSH, LAURA CONNELLY, RATNESHWAR LAL, SUNIL SINHA, University of California, San Diego — The effects of cholesterol in membrane rafts formation remain a mystery even until today. In our study of model membrane multilayer systems consisting of DPPC/DOPC/Cholesterol, we have characterized the morphology changes using AFM and optical microscopy, and the bilayer electron density profile using X-ray reflectivity, as a function of cholesterol concentration. In this presentation, we shall discuss how the cholesterol concentration affects the lipid packing within the bilayer, as well as the interlayer coupling of phase separated domains. X-ray scattering, AFM and optical microscopy which look at different length scales would constitute a complete picture. Our results may shed new light on the understanding of the role of cholesterol in raft formation in biological membranes.

10:24AM A45.00011 ABSTRACT WITHDRAWN –

10:36AM A45.00012 The Effects of Ca^{2+} on the Dynamics of PIP_2 containing Lipid Bilayers , IAN MCCABE, MARTIN FORSTNER, Syracuse University — Changes of intercellular Ca^{2+} concentrations are one of the most ubiquitous signaling events that accompany or precede large scale cellular responses. We are in particular interested in the direct modulation of phosphatidylinositol 4,5-bisphosphate (PIP_2) organization in the membrane due to Ca $^{+2}$. At physiological conditions, PIP_2's headgroup is multiply negatively charged ($>$ 3 effective charges) and interacts with the cationic Ca^{2+}. By coordinating several PIP_2 head-groups, calcium ions can induce condensation and aggregation of PIP_2. A series of experiments were conducted on supported lipid bilayers containing physiological quantities of PIP_2. Fluorescence correlation spectroscopy (FCS) was used to study the response of the PIP_2 to changes in the concentration of Ca^{2+} ions. As Ca^{2+} concentration increases, the FCS indicates that PIP_2 goes from a freely diffusing single species to a multiple species system. The diffusion rates of the additional species decrease with increasing [Ca^{2+}], thus indicating increasing aggregate sizes with increasing, but physiological relevant Ca^{2+} concentrations. An intriguing effect was observed at very low Ca^{2+} levels. The diffusion rate was consistently measured to increase upon addition of small concentrations of Ca^{2+} before decreasing as the concentrations increased. A series of polymer cushioned bilayers were used to attempt to gain greater insight into the nature of the membrane/support interaction and the nature of this effect.

Session A46 SPS: SPS Undergraduate I Hilton Baltimore Holiday Ballroom 5 - Toni Sauncy, American Institute of Physics

8:00AM A46.00001 Electron microscopy of sillenites , CRAIG SCURTI[1], NICOLAS AUVRAY, Department of Physics. University of North Florida., MICHAEL LUFASO, Department of Chemistry. University of North Florida., HIDEO KOHNO, Department of Physics. Osaka University., DANIEL ARENAS, Department of Physics. University of North Florida. — In this undergraduate project, the student performed transmission and scanning electron microscopy measurements on two sillenite compounds: $Bi_{12}SiO_{20}$ and $Bi_{25}InO_{39}$. To our knowledge, the electron diffraction patterns of sillenites have not been reported in the literature before. Our preliminary results show that both the tetravalent and trivalent compound have the sillenite structure. Using concepts from undergraduate solid state physics, the student will explain how the electron diffraction patterns were analyzed.

[1]Undergraduate Student

8:12AM A46.00002 Inverted Pyramid Texturing of Si by Single Exposure Three-beam Interference Lithography , B. SUMMERS, M. LANGHOFF, K. GHOSH, Missouri State University — Increasing energy demands combined with environmental concerns prompts the need for cost-efficient solar cells. One way in which this can be achieved is by etching an inverted nano-pyramid texture into the silicon substrate thereby reducing the requisite amount of material. This is due to the ability of altering the pyramid size such that it corresponds to specific wavelengths, which results in higher light trapping efficiency. These inverted pyramids can be fabricated using three-beam lithography to create the desired hole/dot photoresist pattern in order to etch the substrate. The process can be done as a single exposure by aligning two dielectric mirrors and the sample at specific angles with respect to one another and the incoming laser beam. Using this method, nanostructures of Si and wide bandgap oxide semiconductors such as ZnO and NiO will be fabricated. Detailed results will be discussed in this presentation. This work is partially supported by National Science Foundation (DMR- 0907037).

8:24AM A46.00003 Effects of Sputtering Energy on Surface Defect Formation on Ge(110)[1] , SAMANTHA MACINTYRE[2], MARSHALL VAN ZIJLL, BRET STENGER, MICHAEL NORTON, NOELLE OGURI, SHIRLEY CHIANG, University of California Davis — Pyramid-shaped defects were observed in STM images to form on clean Ge(110) surfaces as a result of argon ion sputtering. By periodically imaging the samples after various numbers of sputtering and annealing cycles, we systematically studied the formation of these defects as a function of the Ar^+ ion sputtering energy. Although the number and size of pyramids increased with sputtering energy from 100 to 200eV, the sample sputtered with 300eV ions showed a very flat surface with very few pyramids. The sample sputtered with 400eV ions appears to have mountain ranges of highly stepped regions with numerous pyramids on the edges, separated by flat valleys of reconstructed c(8x10) surface. Many pyramids are capped by a cluster of atoms, probably carbon, which may have served as the nucleation site. To explain the dependence of defect formation on sputtering energy, we present a mechanism involving competition between uncovering parts of new pyramids and breaking down older pyramids. Using different sputtering energies for controlled defect formation could be an effective tool for controlling island growth at defects on substrates.

8:36AM A46.00004 Studies of electron spin in GaAs quantum dots , DANIEL CRAFT, JOHN COLTON, TYLER PARK, PHIL WHITE, Brigham Young University — We have studied electron spins in GaAs quantum dots with a pump-probe technique that normally yields the T1 spin lifetime, the time required for initially polarized electrons to relax and randomize. Using a circularly polarized laser tuned to the wavelength response of the quantum dot we can "pump" the spins into alignment. After aligning the spins we can detect them using a second, linearly polarized "probe" laser. By changing the delay between the two lasers we can trace out the spin response over time. In contrast with other samples (bulk GaAs and a GaAs quantum well), where the spin response decayed exponentially with time, initial data on the quantum dots has shown an unexpected, oscillating behavior which dies out on the order of 700 ns, independent of both temperature and magnetic field.

8:48AM A46.00005 Surface plasmon enhanced Förster resonance energy transfer in fluorescent molecules using metal wire gratings , ZACH WETZEL, JENNIFER STEELE, Trinity University — Forster resonance energy transfer (FRET) is a powerful tool used to study spatial relationships in biological systems. FRET relies on a nonradiative energy transfer between a donor (D) and acceptor (A) fluorophore. The D-A pair must be located within their Forster radius for an efficient transfer of energy. Surface plasmon (SP) excitations increase the emission of fluorescent molecules by two mechanisms. SPs excited at the fluorophore absorption wavelength increase the excitation rate of the fluorophores. SP modes at the fluorophore emission wavelength provide an additional decay channel for the fluorophores to return to the ground state, increasing the quantum yield and the photostability of the fluorophore. In this study, metal wire gratings were chosen because gratings support SP resonances over a wide wavelength range, allowing overlap for both absorption and emission wavelengths. This research seeks to develop methods for using metal grating SPs to increase the Forster radius for D-A pairs. For this project, gold gratings with a period of 500 nm were fabricated using a nanotransfer printing method. Fluorescence was measured as a function of angle to determine the enhancement. These outcomes will increase the number of physical systems that can utilize FRET.

9:00AM A46.00006 Remotely Tunable Nonlinear Metamaterial at Microwave Frequency , SHELBY LEE, Marietta College, SINHARA SILVA, JIANGFENG ZHOU, University of South Florida — We demonstrate a remotely tunable metamaterial at microwave frequency. The metamaterial consists of a two-gap split ring resonator with varactor diodes integrated in to one of the gaps. By varying a microwave pump signal remotely, the capacitance of the varactor diodes can be controlled. Thus we can tune the working frequency of the metamaterial. Our metamaterials enable an easily-applicable approach to realize tunable frequency without an external bias circuit compared to other tunable metamaterials.

9:12AM A46.00007 Determination of the surface spin-polarization of perovskite oxides using point-contact Andreev reflection spectroscopy[1] , EVERETT GRIMLEY, Centenary College of Louisiana, Shreveport, LA 71104, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Materials with surface spin-polarization are invaluable for incorporation into devices that utilize spin-polarized currents. Point-contact Andreev reflection spectroscopy is currently one of the few techniques capable of direct measurement of surface spin-polarization. Niobium wire was electrochemically etched in a potassium hydroxide solution to form sharp tips which were used to form point-contacts with perovskite oxides in single crystal and thin film forms. Surface spin-polarization values were determined at 4.2 K for several materials including $La_{0.7}Sr_{0.3}MnO_3$, which is a material with purported 100% spin polarization. The results show that surface spin polarization of perovskites is smaller than theoretically predicted.

9:24AM A46.00008 Spin Propagation Through Antiferromagnetic Bulk Structure in Exchange Biased Magnetic Trilayers , MICHAEL CRUMRINE, Beloit College, HILLARY KIRBY, CASEY MILLER, University of South Florida — When an exchange bias is induced in materials with a ferromagnetic (FM) – antiferromagnetic (AF) interface, the interfacial coupling between the antiferromagnet and FM manifests itself as a shift in the magnetic hysteresis loop. It has been an unresolved issue as to the role the bulk spin of the antiferromagnet plays in exchange bias and whether or not exchange bias is entirely an interfacial effect. We fabricated several FM/AF/FM trilayer structures of Py(100Å)/FeMn(x)/$Ni_{69}Cu_{31}$(200Å) with varying antiferromagnet thicknesses and used a field cool procedure to induce an exchange bias. A Magneto-Optical Kerr Effect magnetometer was used to investigate the propagation of spin information through the antiferromagnet by examining the hysteresis loops at different angles of applied field with respect to the magnetization. It was observed that there was no induced exchange bias in the NiCu probe layer for any of the antiferromagnet thicknesses, and we conclude that the patterning of the antiferromagnetic layer transmits no spin information for thicknesses greater than 100Å.

9:36AM A46.00009 Systematic Investigation of Magnetostriction in Composite Magnetorheological Elastomers: the Effect of Particle Shape, Alignment, and Volume Fraction , CHRISTOPHER KASSNER, WILLIAM RIEGER, PARIS VON LOCKETTE, SAMUEL LOFLAND, Rowan University — We have completed a study of the magnetoelastic properties of several types of magnetorheological elastomers (MREs), composites consisting of magnetic particles cured in an elastic matrix. We have made a number of samples with different particle arrangements (pseudo-random and aligned), volume fraction, and particle shape (rods, spheres, and disks) and measured the field dependent strain in order to determine the magnetostriction. We found that the magnetostriction in these samples is highly dependent on the sample particle shape (aspect ratio) and volume fraction and ordering to a lesser extent. While much of the past work has focused on spherical particles, our results indicate that both rods and disks can yield enhanced results. We discuss our findings in terms of magnetic energy of the particles and elastic energy of the matrix. We then consider the issue of optimization. This work was supported in part by NSF Grant CMMI - 0927326.

9:48AM A46.00010 Magnetic-Field Dependence of the Spinon Velocity in the S =1/2 Linear-Chain Heisenberg Antiferromagnet Copper Pyrazine Dinitrate[1] , K.E. MARINO, Pennsylvania State University, C.P. AOYAMA, University of Florida, M.M. TURNBULL, C.P. LANDEE, Clark University, Y. TAKANO, University of Florida — We have measured the specific heat of fully deuterated copper pyrazine dinitrate (CuPzN), a spin-1/2 antiferromagnetic chain compound, at temperatures down to 0.12 K in magnetic fields up to 14 T. This was done to reduce nuclear heat contributions by using deuterated CuPzN and to better define the magnetic heat capacity by taking measurements beyond the saturation field. The results are in good agreement with previous data taken by Hammar *et al.* in fields up to 9 T. The spinon velocity obtained from the specific heat is compared to theoretical predictions as a function of magnetic field.

10:00AM A46.00011 ABSTRACT WITHDRAWN –

10:12AM A46.00012 Bulk Growth of $YBa_2Cu_3O_{7-\delta}$ Superconductors with Enhanced Flux Pinning , JODI-ANN MCLEAN, MATTHEW C. SULLIVAN, JANET HUNTING, Ithaca College — We present our work on the bulk growth of $YBa_2Cu_3O_{7-\delta}$ (Y-123) superconductors with enhanced flux pinning abilities grown using the melt textured growth method. Polycrystalline precursor materials of superconducting Y-123 and insulating Y_2BaCuO_5 (Y-211) are synthesized by sintering commercially available Y_2O_3, CuO, and $BaCO_3$. This process is repeated multiple times to improve the purity and crystal structure of the precursors. In order to make a superconductor with enhanced flux-pinning, it is necessary to add insulating Y-211 impurities to act as pinning centers to the bulk Y-123 superconductor, heat the mixture to temperatures that liquefy the superconducting phase, then cool the mixture slowly to crystallize the superconducting phase. Afterwards we anneal the enhanced flux-pinning superconductor in oxygen to restore oxygen content that was removed during the firing process. We present data on the crystal structure of the precursor materials (Y-123 and Y-211)) and the superconducting transition temperature of the precursor Y-123. In addition, we present data on the transition temperatures and the flux pinning forces of the enhanced flux-pinning superconductors.

10:24AM A46.00013 Growth and Characterization of Na-doped KFeAs , ZACHARY SIMS, GUOTAI TAN, SCOTT CARR, CHENGLIN ZHANG, PENGCHENG DAI, University of Tennessee, Department of Physics, UNIVERSITY OF TENNESSEE, CONDENSED MATTER PHYSICS TEAM — We grew mulitple dopings of Na-doped KFeAs, with a goal of observing an upward shift in the Tc from the KFeAs parent compound and a sharpening of the transistion phase curve. Using a VSM and PPMS to charecterize the magnetic transport, resistivity, and heat capacity, we have come to a conclusion on the sucess of Na-doping into the KFeAs family of FeAs superconductors.

10:36AM A46.00014 Synthesis and Characterization of Ytterbium-filled $CoGe_{1.5}Se_{1.5}$ compositions[1] , WALTER HILL, Department of Engineering, Jacksonville University; Department of Mechanical Engineering, North Carolina Agricultural and Technical State University, YONGKWAN DONG, GEORGE S. NOLAS, Department of Physics, University of South Florida — Polycrystalline skutterudite-related compounds with nominal composition $YbCo_4Ge_{6+x}Se_{6-x}$($0 < x < 1$) were prepared by melting of the constituent elements followed by annealing, and subsequent hot-pressing for densification. Structural and phase characterized was achieved by X-ray diffraction and electron microscopy. The crystal structure of skutterudites allows for voids within the crystal lattice that can be filled by "guest atoms" such as ytterbium. It is well known that this guest-atom-filling of the voids can result in significant phonon scattering, although these materials possess relatively good electrical properties, and are therefore thought of as PGEC (Phonon Glass Electron Crystal) materials. The goal of this research was to synthesize these skutterudite-related compounds and examine their thermoelectric properties. Their composition and properties will be discussed.

10:48AM A46.00015 Designing Drops, Loops, and Hills: The Physics behind Roller Coaster Design , KATHARYN CHRISTIANA, CAROLINA ILIE, Physics Department, State University of New York at Oswego — Almost everyone has seen a roller coaster at one time in their life. They range in type from old wooden coasters from decades passes to modern machines made of steel that allow you to stand up while riding. The basic physics behind these machines is relatively simple, but in the modern world we strive to design bigger and better machines that push the human body and the laws of physics to their limits. But how do the designers of these rides maintain the balance between making riders feel like they're on the brink of death while keeping them completely safe? The answer can be found in basic physics and mechanical engineering. This is a part of the honors thesis that focuses on the mechanical principles applied in roller coaster design. The theoretical part of the thesis will be complemented by a full small scale ride design.

Monday, March 18, 2013 8:00AM - 11:00AM –

Session A47 DBIO: Invited Session: Excitable Dynamics in Biological Systems Hilton Baltimore Holiday Ballroom 6 - Pankaj Mehta, Boston University

8:00AM A47.00001 Cell signaling at the single-cell level , MICHAEL ELOWITZ, California Institute of Technology — No abstract available.

8:36AM A47.00002 Excitability in Dictyostelium development , DAVID SCHWAB, Princeton University — Discovering how populations of cells reliably develop into complex multi-cellular structures is a key challenge in modern developmental biology. This requires an understanding of how networks at the single-cell level, when combined with intercellular signaling and environmental cues, give rise to the collective behaviors observed in cellular populations. I will present work in collaboration with the Gregor lab, showing that the signal-relay response of starved cells of the amoebae Dictyostelium discoideum can be well modeled as an excitable system. This is in contrast to existing models of the network that postulate a feed-forward cascade. I then extend the signal-relay model to describe how spatial gradient sensing may be achieved via excitability. One potential advantage of relying on feedback for gradient sensing is in preventing "cheaters" that do not produce signals from taking over the population. I then combine these models of single-cell signaling and chemotaxis to perform large-scale agent-based simulations of aggregating populations. This allows direct study of how variations in single-cell dynamics modify population behavior. In order to further test this model, I use the results of a screen for mutant cell lines that exhibit altered collective patterns. Finally, I use an existing FRET movie database of starved cell populations at varying cell densities and dilution rates to study heterogeneity in repeated spatio-temporal activity patterns.

9:12AM A47.00003 Excitability in neural coding , ADRIENNE FAIRHALL, University of Washington — No abstract available.

9:48AM A47.00004 Action Potential Initiation in the Hodgkin-Huxley Model , MICHAEL BRENNER, Applied Mathematics & Applied Physics, Harvard University — No abstract available.

10:24AM A47.00005 Cell motility: Combining experiments with modeling[1] , WOUTER-JAN RAPPEL, rappel@physics.ucsd.edu — Cell migration and motility is a pervasive process in many biology systems. It involves intra-cellular signal transduction pathways that eventually lead to membrane extension and contraction. Here we describe our efforts to combine quantitative experiments with theoretical and computational modeling to gain fundamental insights into eukaryotic cell motion. In particular, we will focus on the amoeboid motion of Dictyostelium discoideum cells.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B1 DCMP: Invited Session: Logical Spin Qubits for Quantum Computation Ballroom I - Amir Yacoby, Harvard University

11:15AM B1.00001 Entanglement of Singlet-Triplet Qubits , MICHAEL SHULMAN, Harvard University — Spins in semiconductor quantum dots are promising candidates for the building blocks of a quantum information processor due to their potential for miniaturization and scalability. Singlet-triplet (S-T0) qubits, a certain type of spin qubit, store information in the joint spin state of two electrons. However, these qubits' weak interaction with the environment, which leads to their long coherence times, makes two-qubit operations challenging. We perform the first two-qubit operation between two S-T0qubits, exploiting the capacitive coupling between two adjacent qubits to generate a CPHASE gate. In order to combat low frequency noise we use a dynamically decoupled sequence that maintains the two-qubit coupling while decoupling each qubit from its fluctuating environment. Using state tomography we show that the two-qubit operation has the intended effect on the state of the qubits, and we provide definitive proof of entanglement by extracting a concurrence of 0.44 and a Bell state fidelity of 0.72. This two-qubit interaction lends itself to easily implemented improvements, which promise to generate higher fidelity entangled states that can be the basis for establishing a scalable architecture for quantum information processing.

11:51AM B1.00002 The exchange-only spin qubit , CHARLES MARCUS, Niels Bohr Institute, University of Copenhagen — No abstract available.

12:27PM B1.00003 Exchange-based CNOT gates for singlet-triplet qubits with spin orbit interaction. , JELENA KLINOVAJA, Department of Physics, University of Basel — We propose a scheme for implementing the CNOT gate over qubits encoded in a pair of electron spins in a double quantum dot [1]. The scheme is based on exchange and spin-orbit interactions and on local gradients in Zeeman fields. We find that the optimal device geometry for this implementation involves effective magnetic fields that are parallel to the symmetry axis of the spin-orbit interaction. We show that the switching times for the CNOT gate can be as fast as a few nanoseconds for realistic parameter values in GaAs semiconductors. Guided by recent advances in surface codes, we also consider the perpendicular geometry. In this case, leakage errors due to spin-orbit interaction occur but can be suppressed in strong magnetic fields.

1:03PM B1.00004 Coherent Control and Manipulation of Three Spin States in a Triple Quantum Dot[1] , ANDREW SACHRAJDA, National Research Council of Canada — The triple quantum dot energy level spectrum is far more complex than its double quantum dot counterpart. As a result it is a challenge to cleanly manipulate only the two required qubit states without invoking more complex multi- state coherent evolution. In this talk I will describe experiments and modeling of lateral triple quantum dot devices where by suitable device gate (i.e. energy level spectrum) tuning and pulse characteristics we were able to characterize and manipulate various three spin qubit species. In particular I will describe measurements where the Landau-Zener –Stückelberg approach previously demonstrated in double dots is extended to three- interacting spin states permitting us to demonstrate phenomena such as pairwise exchange control. I will also demonstrate how by tuning the experimental parameters one can controllably switch to coherent oscillations originating from alternative potentially useful qubit states and how to distinguish them.

1:39PM B1.00005 Two single spin qubits with universal control and control of spin entanglement with exchange coupling[1] , SEIGO TARUCHA, The University of Tokyo — Single qubits and two-qubit gates are building blocks to prepare a universal set of logical operations. We use a micro-magnet technique to implement single spin qubits with individual quantum dots and two-qubit gates with inter-dot exchange coupling. I will talk about our recent experiments of a combined X-gate and exchange control to modulate and detect the degree of spin singlet coupling. The gate fidelity is restricted by X-gate operation time and fidelity. The X-gate is prepared by oscillating an electron inside a quantum dot with microwave (MW) in the presence of a micro-magnet induced field gradient. We have recently raised the MW power and optimized the magnet design to reduce the X-gate time < 3 nsec with improved gate fidelity much shorter than the dephasing time. We have also developed a technique to use the micro-magnet induced inhomogeneous Zeeman field to make faste Z-gate and CPHASE.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B2 DCMP: Invited Session: 2D Charge Ordering in Under-Doped Cuprates Ballroom II - Zhi-Xun Shen, Stanford University

11:15AM B2.00001 Incommensurate charge density fluctuations in underdoped YBCO detected by resonant x-ray scattering , GIACOMO GHIRINGHELLI, Politecnico di Milano - Italy — A key issue in high T_c superconductivity is the short and mid range ordering of spin and charge degrees of freedom when doping disrupts the long range antiferromagnetic order of parent compounds. Cu sites are the main, although not the only, actors in the play. Inelastic and elastic scattering of x rays, when performed at the Cu L_3 absorption resonance, can be used to map the spin and charge excitation spectra and, simultaneously, to unveil the presence of spatial modulations in the charge or spin densities. We have used angle-resolved resonant inelastic soft x-ray scattering (RIXS) and resonant elastic soft x-ray scattering (REXS) to identify two-dimensional charge fluctuations with an incommensurate periodicity of ~ 3.2 lattice units in the copper oxide planes of the superconductors (Y,Nd)$Ba_2Cu_3O_{6+x}$ with hole concentrations $0.09 < p < 0.13$ per planar Cu ion [G. Ghiringhelli et al, Science 337, 821 (2012)]. The intensity and correlation length of the fluctuation signal increase strongly upon cooling down to the superconducting transition temperature, T_c; further cooling below T_c abruptly reverses the divergence of the charge correlations. In combination with prior observations of a large gap in the spin excitation spectrum, these data indicate an incipient charge-density-wave instability that competes with superconductivity. Further measurements on an Ortho III sample have confirmed that the charge fluctuations are independent of the chain ordering [A. J. Achkar et al, Phys. Rev. Lett. 109, 167001 (2012)]. Put into perspective, these results show that often elastic and inelastic x-ray scattering experiments should be ideally performed jointly, to explore with the greatest sensitivity charge and spin fluctuations [L. Braicovich et al, Phys. Rev. Lett. 104, 077002, (2010)].

11:51AM B2.00002 Charge and spin correlations in high temperature superconductors[1] , STEPHEN HAYDEN, University of Bristol — The cuprate high temperatures superconductors are characterised by numerous competing, and in some cases, co-existing broken symmetries. A important question is to what extent such additional ordered states exist for compositions with high superconducting transition temperatures. I will discuss high-energy X-ray diffraction measurements which show that a charge density wave state (CDW) develops at zero field in the normal state of superconducting $YBa_2Cu_3O_{6.67}$ (T_c = 67 K). This material has a hole doping of 0.12 per copper and a well-ordered oxygen chain superstructure. Below T_c, the application of a magnetic field suppresses superconductivity and enhances the CDW. We find that the CDW and superconductivity are competing orders with similar energy scales, and the high-T_c superconductivity forms from a pre-existing CDW environment. Our results provide a mechanism for the formation of small Fermi surface pockets which can explain the negative Hall and Seebeck effects and the T_c plateau in this material.

[1]Work performed in collaboration with J. Chang, E. Blackburn, A. T. Holmes, N. B. Christensen, J. Larsen, J. Mesot, Ruixing Liang, D. A. Bonn, W. N. Hardy, A. Watenphul, M. v. Zimmermann and E. M. Forgan.

12:27PM B2.00003 Interplay between the pseudogap, mode coupling and superconductivity in Bi-based cuprates[1] , MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory — Complexity of the high-Tc cuprate superconductors is partly due to the coexisting energy scales that are of the order of superconducting gap (<50 meV). The pseudogap (<100 meV) and bosonic mode (<100 meV) could be relevant to superconductivity, but they have not been understood in a unified picture. We first show the commencement of the pseudogap state at temperature T* using three different techniques (ARPES, polar Kerr effect, and Time-resolved reflectivity) on the same optimally doped Bi2201 crystals. The result suggests that the pseudogap is a disinct phase that shows broken symmetry,[2,3] which could be consistent with the two-dimentional charge ordering observed by STM and scattering measurements. Further, we discuss how this distinct pseudogap order is entangled with superconductivity below Tc. In Bi2212, by analyzing the ARPES spectral weihgt in the antinodal region, we show compelling evidence for the dynamic competition between the two order parameters for the pseudogap and superconductivity as a function of temperature.[4] Such competition can naturally result in the shift of the critical point for the pseudogap.[5] Moreover, by studying the detailed temperature and doping dependence of the spectral lineshape in the antinodal region, we reveal that the interplay between the pseudogap, bosonic-mode coupling and superconductivity with similar energy scales is crucial and they have to be considered in a integrated picture to understand the cuprates electronic structure.[6]

1:03PM B2.00004 Pseudogap signatures measured in the Fermi surface of underdoped YBCO by quantum oscillations , SUCHITRA E. SEBASTIAN, University of Cambridge — Solving the riddle of the pseudogap state in underdoped high temperature superconductors is critical to the understanding of the origin of high temperature superconductivity. Quantum oscillations performed on single crystals of the family of underdoped YBCO cuprates reveal small Fermi surface pockets in the normal state accessed at low temperatures and high magnetic fields. It has been widely thought, however, that high magnetic fields cause this state to be significantly different from the mysterious pseudogap state measured at high temperatures and low magnetic fields. In this talk I will present a quantum oscillation study of underdoped $YBa_2Cu_3O_{6+x}$ up to magnetic fields of 100 T that reveals a dimensional collapse of the Fermi surface due to a drastic reduction in c-axis hopping, identical to the pseudogap signature measured in the low magnetic field regime. We therefore conclude that the fundamental properties of the pseudogap are encoded in the Fermi surface, an understanding of which is critical to uncovering the origin of the pseudogap in high temperature superconductors. Possible mechanisms are discussed to explain the origin of the Fermi surface in underdoped $YBa_2Cu_3O_{6+x}$. This work was performed in collaboration with G. Lonzarich (University of Cambridge), N. Harrison, M. Altarawneh, F. Balakirev (Los Alamos National Laboratory), and R. Liang, W. Hardy, D. Bonn (University of British Columbia)

1:39PM B2.00005 Ultrasonic signatures at the superconducting and the pseudogap phase boundaries in cuprates , ALBERT MIGLIORI, Los Alamos National Laboratory — A major issue in the understanding of cuprate superconductors is the nature of the metallic state from which high temperature superconductivity emerges. Central to this issue is the pseudogap region of the doping-temperature phase diagram that extends from room temperature to the superconducting transition. To date there is no thermodynamic evidence for a phase boundary. We address this by measuring the elastic response of detwinned single crystals and observe a discontinuity in the elastic moduli across the superconducting transition with magnitude requiring that pair formation is coincident with superconducting coherence and a phase transition at the pseudogap boundary. In slightly overdoped YBCO that transition is below Tc, extending the pseudogap phase boundary inside the superconducting dome. This supports a description of the metallic state in cuprates where a pseudogap phase boundary evolves into a quantum critical point masked by the superconducting dome.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B3 DCMP: Invited Session: Frustration and Quantum Criticality Ballroom III - Leon Balents, University of California at Santa Barbara

11:15AM B3.00001 Superconductivity Near Quantum Critical Points , GILBERT G. LONZARICH, Shoenberg Laboratory for Quantum Matter, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK — The study of itinerant-electron systems on the border of charge and spin density wave transitions at low temperatures is leading to an increasing number of discoveries of unusual forms of superconductivity and other types of quantum order. Examples will be reviewed of electron-electron pair instabilities in particular on the border of ferromagnetic, antiferromagnetic, ferroelectric and structural quantum phase transitions. The superconducting transition temperature in a number of nearly magnetic metals from heavy fermion compounds to the copper oxide superconductors appears to scale with the characteristic spin fluctuation temperature. These best known materials will be compared and contrasted with examples from other classes of materials in which the spin fluctuation temperature far exceeds the peak of the superconducting transition temperature in the temperature-pressure phase diagram near a magnetic quantum critical point.

11:51AM B3.00002 Quantum spin liquid in organics with quasi-triangular lattices , KAZUSHI KANODA, University of Tokyo — No abstract available.

12:27PM B3.00003 A Topological Spin Glass State of a Frustrated Magnet , SEUNG-HUN LEE, University of Virginia — We will present a simple way of understanding the physics of the kagome-triangular-kagome trilayer antiferromagnet by mapping the magnetic interactions onto a problem of an ordered tricolor and a disordered binary sign degree of freedom. By doing so, We will show a systematic way of constructing different classical ground states, and will identify possible zero-energy excitations that involve "partial but extended" numbers of spins in the system. Due to the unique properties of the ground state, we argue that a topological spin glass is the ground state for the quasi-two-dimensional frustrated magnet.

1:03PM B3.00004 On Short Ranged Resonating Valence Bond Liquids , SHIVAJI SONDHI, Princeton University — Over 40 years ago, P W Anderson proposed the short ranged resonating valence bond state as an alternative to Neel order in antiferromagnets with strong fluctuations—in hindsight, the first proposal for a topologically ordered Z_2 spin liquid. In the last year, convincing numerical evidence has accumulated for the existence of such Z_2 spin liquids in short ranged Hamiltonians on simple lattices in two dimensions. I will sketch the intellectually productive historical route between these two developments and survey what we now know about the physics of the short ranged RVB and allied states of matter.

1:39PM B3.00005 Critical Behavior of a Strongly-Interacting 2D Electron System[1] , MYRIAM P. SARACHIK, City College of New York - CUNY, New York, NY 10031, USA — Two-dimensional (2D) electron systems that obey Fermi liquid theory at high electron densities are expected to undergo one or more transitions to spatially and/or spin-ordered phases as the density is decreased, ultimately forming a Wigner crystal in the dilute, strongly-interacting limit. Interesting, unexpected behavior is observed with decreasing electron density as the electrons' interactions become increasingly important relative to their kinetic energy: the resistivity undergoes a transition from metallic to insulating temperature dependence; the resistance increases sharply and then saturates abruptly with increasing in-plane magnetic field; a number of experiments indicate that the electrons' effective mass exhibits a substantial increase approaching a finite "critical" density. There has been a great deal of debate concerning the underlying physics in these systems, and many have questioned whether the change of the resistivity from metallic to insulating signals a phase transition or a crossover. In this talk, I will report measurements [1] that show that with decreasing density n_s, the thermopower S of a low-disorder 2D electron system in silicon exhibits a sharp increase by more than an order of magnitude, tending to a divergence at a finite, disorder-independent density n_t, consistent with the critical form $(-T/S) \propto (n_s - n_t)^x$ with $x = 1.0 \pm 0.1$ (T is the temperature) [2]. Unlike the resistivity which may not clearly distinguish between a transition and crossover behavior, the thermopower provides clear evidence that a true phase transition occurs with decreasing density to a new low-density phase.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B4 DAMOP DCMP: Invited Session: Cold Atoms on Higher Orbital Bands Ballroom IV - Erhai Zhao, George Mason University

11:15AM B4.00001 Unconventional superfluidity in higher bands of an optical lattice , ANDREAS HEMMERICH, Institut für Laser-Physik, Hamburg University — Atoms trapped in optical lattices have been used successfully to study many-body phenomena. However, the shape that bosonic ground-state wavefunctions can take is limited, apparently compromising the usefulness of this approach. Such limitations, however, do not apply to excited states of bosons. The study of atomic superfluids realized in higher Bloch bands, where orbital degrees of freedom are essential, can bring the world of optical lattices closer to relevant condensed matter systems. I will discuss our observations of long coherence times, chiral superfluid order and topological features in higher bands in a square optical lattice.

11:51AM B4.00002 Beyond Standard Fermi Hubbard Models[1] , MACIEJ LEWENSTEIN, ICFO - Institut of Photonic Sciences — In my talk I will focus on novel physics and novel quantum phases that are expected in a system of ultracold fermionic atoms with long range interactions, such dipolar ones. I will discuss various terms in the Hubbard model that, normally neglected, have to be included in the theory. These terms involve both lowest band physics, as well as higher bands. I will describe several exemplary effects that new terms may lead to: spontaneous breaking of symmetries, such as time-reversal, smectic-like metal phases, spontaneous formation of exotic lattices and 3D textures.

[1]supported by ERC Grant QUAGATUA

12:27PM B4.00003 Higher orbital physics and artificial gauge fields with ultracold quantum gases , KLAUS SENGSTOCK, Universitaet Hamburg, ILP, Luruper Chaussee 149, 22761 Hamburg — Recently the physics of quantum gases in higher orbitals attracted a lot of attention, theoretically and experimentally. We report on studies of a new type of superfluid described by a complex order parameter, resulting from an interaction-induced hybridization of the two lowest orbitals for a binary spin-mixture. As a main result we observe a quantum phase transition between the normal superfluid and this unconventional superfluid phase, where the local phase angle of the complex order parameter is continuously twisted between neighboring lattice sites [1]. In addition we discuss new experimental work on the creation of artificial gauge potentials for neutral atoms in 1D and 2D lattices, which do not rely on the internal structure of the atoms. Via a time-dependent driving of the optical lattice we have full control over amplitude and phase of the complex valued hopping parameters. In a 2D triangular lattice, we demonstrate the realization of gauge invariant staggered fluxes [2]. Our system consists of an array of tubes filled with bosonic atoms having a well-defined local phase. The phase distribution obtained in presence of large amplitude staggered fluxes – where frustration plays a key role - obeys two fundamental symmetries, the discrete Ising symmetry (Z2) and a continuous global phase symmetry (U(1)). Via the full control of the staggered gauge fields [3], we are able to break the Ising symmetry on purpose which means lifting the degeneracy of the two possible Ising states, in analogy to a longitudinal homogenous magnetic field in the standard Ising-Spin model. The measurements reveal "textbook like" magnetization curves with the well known dependence on both, the external magnetic field and the temperature. We observe a thermally driven phase transition from an ordered Ising (ferromagnetic) to an unordered (paramagnetic) state. Future directions to combine orbital physics and gauge fields will be discussed.

[3] Struck et al., PRL 108, 225304 (2012)

1:03PM B4.00004 Orbital physics in one dimensional optical lattices[1] , XIAOPENG LI, University of Pittsburgh — We explore orbital physics of fermions and bosons in one dimensional optical lattices. In a system of one dimensional p-orbital bosons, various phases, including anti-ferro-orbital Mott, anti-ferro-orbital superfluid and para-orbital superfluid, have been found. Signatures of phase transitions, in particular time-reversal symmetry breaking, in time-of-flight image are predicted. A fermionic ladder system composed of s and p orbitals is proposed, and we find a topological state featuring fractional defects. An equivalent of spin-orbit coupling naturally arises, not requiring artificial gauge field, in this quantum orbital ladder when the s and p orbital states are identified as a pseudo-spin 1/2. Extending this ladder system to two dimensions we find a flat-band protected by parity. The flat-band makes it plausible to study strongly correlated physics in this system. We also discuss the connection of this fermionic ladder to frustrated π flux models and spin-orbital coupled fermions.

[1]A. W. Mellon Fellowship, AFOSR (FA9550-12-1-0079), ARO (W911NF-11-1-0230), ARO-DARPA-OLE (W911NF-07-1-0464)

1:39PM B4.00005 Generation and exploration of the Spin-Orbit coupled Bose gas , JIAN-WEI PAN, Hefei National Lab for Physical Sciences a Microscale and Department of Modern Physics, University of Science and Technology of China, Hefei, 230026 — To generate an artificial gauge field with ultracold quantum gas becomes a very hot topic in last few years and will continue to be attractive for ultracold atomic and condensed matter physics in the coming future. Many interesting and important topics such as Fractional Quantum Hall effect, Spin-orbit coupling and Topological insulator are connected to this topic very closely. Here we present our recent experimental progress of the synthesized gauge potential and the spin-orbit coupled Bose-Einstein condensate (BEC) in optical dipole trap. Raman coupling technique and a bias magnetic field is applied to tune the structure of the gauge potential and spin-orbit coupling. Several fundamental properties of spin-orbit coupled BEC is experimentally studied including the properties of collective dipole oscillation, the stability of excited dressed state, the critical temperature of spin-orbit coupled Bose gas and the formation of magnetic order during evaporative cooling. These studies enrich the knowledge of this field and further explorations are also in planning.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B5 DMP: Focus Session: Van der Waals Bonding in Advanced Materials - Surfaces, Growth, and Friction 301 - Jacqueline Krim, North Carolina State University

11:15AM B5.00001 Exploiting London dispersion forces in nonequilibrium growth of surface-based nanostructures[1] , ZHENYU ZHANG, Univ of Science & Technology of China & Univ of Texas at Austin — London dispersion force describes the weak interaction between transient dipoles or multipoles associated with different parts of matter, and accounts for a major part of the attractive van der Waals (vdW) force. It is ubiquitous in nature, yet its importance in various physical and chemical processes just starts to be increasingly recognized. Such advances through definitive quantitative studies are largely enabled by the availability of more accurate descriptions of the weak interactions associated with long-range electron correlation effects within first-principles approaches. The present talk contains two parts, both obtained within the vdW-DF scheme on the theory side. In the first part, we critically assess the binding strengths of different classes of adatoms on ultrathin metal films of varying thicknesses. For inert gas atoms such as Xe, the London dispersion force is found to drastically enhance their adsorption, but the overall binding behavior depends only weakly on the film thickness. In contrast, for atoms with unpaired valence electrons such as H or O, the overall binding is much stronger, and also depends more sensitively on the film thickness, but with a much weaker and (in some cases) repulsive vdW contribution. These results have important implications in our developing a better understanding of atomic and molecular adsorption on different metal substrates. In the second part, we demonstrate unambiguously the decisive role of London dispersion force in non-equilibrium growth of ordered nanostructures on metal substrates using aromatic source molecules. Our multi-scale modeling integrating first-principles calculations with kinetic rate equation analysis shows that a drastic reduction in the growth temperature, from 1000°C to (250-300)°C, can be achieved in graphene growth on Cu(111) when the typical carbon source of methane is replaced by benzene or p-Terphenyl. The enhanced London dispersion forces effectively prevent easy desorption of the adsorbed molecules, facilitating their dehydrogenation, and promoting subsequent graphene growth at much lower temperatures. These strong predictions are further validated quantitatively in our experimental tests. We also demonstrate that the general trends established above are broadly applicable in graphene growth using other aromatic carbon sources.

[1]Work done in collaboration with Jin-Ho Choi, Ping Cui, Guo Li, Wenguang Zhu on the theory side, and Zhancheng Li, Xiaodong Fan, and Changgan Zeng on the experimental side; supported in part by NSF and MOST of China, USNSF, and USDOE.

11:51AM B5.00002 Van der Waals density functional applied to adsorption systems[1] , IKUTARO HAMADA, Advanced Institute for Materials Research (AIMR), Tohoku University — The van der Waals density functional (vdW-DF) [1] is a promising density functional to describe the van der Waals forces within density functional theory. However, despite the recent efforts [2], there is still room for further improvement, especially for describing molecular adsorption on metal surfaces. I will show that by choosing appropriate exchange and nonlocal correlation functionals, it is possible to calculate geometries and electronic structures for adsorption systems accurately within the framework of vdW-DF. Applicability of the present approach will be illustrated with its applications to graphene/metal [3], fullerene/metal [4], and water/graphene interfaces [5].

12:03PM B5.00003 Nanotribological Properties of Positively and Negatively charged nanodiamonds as additives to solutions[1] , ZIJIAN LIU, STEVEN CORLEY, North Carolina State University, OLGA SHENDEROVA, International Technology Center, DONALD BRENNER, JACQUELINE KRIM, North Carolina State University — Nano-diamond (ND) particles are known to be beneficial for wear and friction reduction when used as additives in liquids,[1] but the fundamental origins of the improvement in tribological properties has not been established. In order to explore this issue, we have investigated the nanotribological properties of ND coated with self-assembled monolayers (SAM) as additives to solutions, employing gold/chrome coated quartz crystal microbalances (QCM). Measurements were performed with the QCM initially immersed in deionized water. ND particles with positively and negatively charged SAM end groups were then added to the water, while the frequency and amplitude of the QCM were monitored. Negative shifts in both the QCM frequency and amplitude were observed when ND with positively charged SAM end groups were added, while positive shifts in both the QCM frequency and amplitude were observed when ND with negatively charged ND end groups were added . The results are consistent with a lubricating effect for the negatively charged ND, but were only observed for sufficiently small negative ND particle size. Experiments on QCM surfaces with differing textures and roughness are in progress, to determine the separate contributing effects of surface roughness charge-water interactions. 1. V. N. 12:15PM B5.00004 Adhesion in Nanodiamond Particles , VASUDEVA RAO ARAVIND, LUKE LUTKUS, BENJAMIN LEGUM, Clarion University, CLARION UNIVERSITY COLLABORATION — Due to their excellent mechanical properties and biologically non-toxic nature, nanodiamonds show great promise for applications in tribology, lubrication, drug delivery, tissue scaffolds and surgical implants. In order to design effective nanocomposites and other biomedical systems exploiting these properties, it is important to understand the properties and mechanisms by which nanodiamonds adhere to other materials, and how they behave at interfaces. In this article, the adhesive force between nanodiamond particles and the silicon scanning probe microscope tip are reported. The adhesive force can be correlated to the purity and functionalization of nanodiamond surface, and the values range from 0.1nN to 2.0nN for the samples studied. It is observed that the lateral forces applied by the scanning probe tip can cause the adhesive forces to increase by an order of magnitude from 0.1 to 2.0nN at regions where the tip experiences maximum contact force.

12:27PM B5.00005 ABSTRACT WITHDRAWN –

12:39PM B5.00006 Adsorption and intercalation of Cs atoms on epitaxial graphene on Ir(111) , PREDRAG LAZIC, Theoretical Physics Division, Rudjer Boskovic Institute, Bijenicka Cesta 54, Zagreb, Croatia, MARIN PETROVIC, IVA SRUT, IVO PLETIKOSIC, MILORAD MILUN, PETAR PERVAN, Institut za fiziku, Bijenicka 46, Zagreb, Croatia, SVEN RUNTE, CARSTEN BUSSE, THOMAS MICHELY, II. Physikalisches Institut, Universitat zu Koln, 50937 Koln, Zulpicher Str. 77, Germany, DAMIR SOKCEVIC, RADOVAN BRAKO, Theoretical Physics Division, Rudjer Boskovic Institute, Bijenicka Cesta 54, Zagreb, Croatia, NICOLAE ATODIRESEI, Peter Grunberg Institut (PGI-1) and Institute for Advanced Simulation (IAS- 1), Forschungszentrum Julich and JARA, 52425 Julich, Germany, JUREK SADOWSKI, ZHI-HU PAN, TONICA VALLA, Brookhaven National Lab, Upton, New York 11973, USA, MARKO KRALJ, Institut za fiziku, Bijenicka 46, Zagreb, Croatia — From the experimental studies of surface adsorption of Cs atoms and their intercalation under epitaxial graphene on Ir(111) it is known that both - adsorbed and intercalated phase of Cs atoms coexist. However, adsorbed phase is realized as a diluted superlattice adlayer of Cs atom while intercalated phase is a dense Cs layer. The preference for intercalated phase at large Cs layer densities can not be obtained from the DFT calculations with semilocal (GGA) functionals. Only after the van der Waals interaction is taken into account the agreement with experiment is achieved. From the results of calculations it follows that the main energy contribution responsible for the switching of preference from adsorption to intercalation is the graphene delamination energy from the Ir(111) surface which is dominantly of the van der Waals nature.

12:51PM B5.00007 Structure and Morphology of Copper Phthalocyanine Films on Graphene and Graphite , TERRY MCAFEE, TIANSHUAI GUAN, SEAN STEWART, ELIOT GANN, JACK ROWE, HARALD ADE, DANIEL DOUGHERTY, North Carolina State University — Indium tin oxide (ITO) is the most widely used anode in organic photovoltaic (OPV) applications. It has several disadvantages, including elemental scarcity and a very rough surface morphology that influences the structure of organic thin film active layers. Alternative transparent conducting anode materials must be identified for use in organic optoelectronic devices. An exciting possibility is the use of graphene since it offers high performance electrical characteristics, good transparency, and a very flat template for high quality film growth. Hard x-ray scattering reveals a "face-on" orientation of copper phthalocyanine (CuPc) on graphene, in contrast to its "edge-on" orientation on ITO. This is advantageous for solar cells due to enhanced absorption as well as improved charge transport to the anode via pi-pi stacking. Atomic force microscopy shows that CuPc forms large crystalline domains on graphene that should improve carrier mobility, as well as increase the exciton diffusion length leading to improved charge separation. These unique characteristics suggest significantly improvements in the Jsc and FF of CuPc based OPV devices using graphene as an anode material.

1:03PM B5.00008 Atomic Friction Studies of Nitrogen and Oxygen Uptake on Magnetic substrates by means of the Quartz Crystal Microbalance Technique[1] , ZACHARY FREDRICKS, KEELEY STEVENS, JACQUELINE KRIM, North Carolina State University — In the study of friction at the nanoscale, phononic, electrostatic, conduction electron and magnetic effects all contribute to the dissipation mechanisms [1]. Magnetic contributions have been alluded to in past studies, but remain poorly characterized. We will report here our efforts to detect magnetic friction for sliding adsorbed films on various magnetic films substrates in the presence and absence of an external field. Using a quartz crystal microbalance (QCM), we record the sliding friction of liquid monolayers of nitrogen, a diamagnetic material, as well as liquid oxygen, a paramagnetic material, on nickel alloy and graphene/nickel surfaces. In the prior literature, these systems have been reported to exhibit sensitivity to external fields.

1:15PM B5.00009 Developing of van der Waals parameters for graphitic carbon-water interaction using ab initio methods , YANBIN WU, NARAYANA ALURU, University of Illinois — In this study, graphitic carbon-water van der Waals interaction parameters are developed entirely from first-principle calculation data. First, the Møller-Plesset perturbation theory of the 2nd order (MP2) method is employed to compute the polycyclic aromatic hydrocarbon-water interaction energies. The proper size of basis sets is utilized in the MP2 calculations and the energy component analysis is performed to extrapolate to infinite-sized graphene limit. Then, graphitic carbon-water interaction parameters are developed based on the MP2 results from this work and the ab initio data available in the literature from other methods such as random-phase approximation (RPA), diffusion Monte Carlo (DMC), density functional theory-symmetry-adapted perturbation theory (DFT-SAPT) and couple cluster treatment with single and double excitations and perturbative triples (CCSD(T)). We evaluate the accuracy of the interaction parameters by predicting water contact angle on graphite and compare it with experimental data. The interaction parameters based on RPA, DFT-SAPT and corrected DMC data predict contact angles which agree well with experiments, while the parameters based on MP2 and CCSD(T) data have the tendency to underestimate the contact angle.

1:27PM B5.00010 Field-effect modulation of water adsorption on the TiO_2 (110) surface from van der Waals density functional theory[1] , ABRAHAM HMIEL, YONGQIANG XUE, State University of New York at Albany - College of Nanoscale Science and Engineering — The interaction of water and the titanium dioxide surface has been identified as a target problem across many possible fields of application of electrochemical devices and sensors, as the surface chemistry at the interface is not well-understood. This work applies self-consistent van der Waals density functional theory and the effective screening medium theory[2] to study the surface chemistry and wetting of H_2O on nanostructured TiO_2 surfaces. Water-TiO_2 substrate interactions are probed from the monomer limit up to monolayer coverage under an external electric field in a charged capacitor model. We illustrate the competitive effect between the electric field and the descriptions of the hydrogen bonding induced by the application of the van der Waals functional by analyzing the energetics, charge partitioning, and bonding at the interface.

1:39PM B5.00011 Thermodynamic Stability and Structure of Oxidized Cu(110) Surfaces: The Critical Role of non-Local Interactions , JOSEPH BAMIDELE, Dept. of Physics, King's College London, The Strand, London, U.K., JAN BRNDIAR, IVAN STICH, Inst. of Physics, Slovak Acad. of Sciences, 84511 Bratislava, Slovakia, LEV KANTOROVITCH, Dept. of Physics, King's College London, The Strand, London, U.K. — Thermodynamic stability of oxidized Cu(110) surface is studied using DFT techniques. At high oxygen exposures standard techniques predict more phases to be quasi-isoenergetic, whereas experiments observe only the $c(6 \times 2)$ phase at high oxygen exposures clearly indicating this phase to be the ground-state separated by considerable energy differences from other candidates. We show that this surface system is stabilized by a delicate coexistence and balance of chemi- and physi-sorption. Agreement with experiments is only achieved if the van der Waals interaction between the surface templates is accounted for in DFT thermodynamics. Moreover, van der Waals stabilization of the surface structure is anticipated to be a general feature present also in the cases of other related surfaces.

1:51PM B5.00012 A Density Functional Theory Examination of the Local Conformational Energetics of Normal and Epigenetically Modified Duplex DNA , TAHIR YUSUFALY, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, WILMA OLSON, Department of Chemistry, Rutgers University, Piscataway, NJ — We report density functional theory calculations of various local regions of duplex DNA, including hydrogen bonded base pairs, stacked nearest-neighbor bases, and sugar-phosphate backbones. Special attention is given to the methylation of 5-cytosine, an epigenetic modification believed to play a key role in eukaryotic gene regulation. Energetically stable molecular conformations are identified and their elastic properties analyzed. Our results are compared with previous ab initio studies and high-resolution crystalline structural data.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B6 DMP: Focus Session: CVD Graphene - Growth and Characterization 302 - Luigi Colombo, Texas Instruments

11:15AM B6.00001 Ultrafast dynamics of non-thermal hot electrons in chemical vapor deposited graphene , KUAN-CHUN LIN, MING-YANG LI, CHENG-CHUNG CHI, JENG-CHUNG CHEN, None, DEPARTMENT OF PHYSICS, NATIONAL TSING-HUA UNIVERSITY TEAM — The relaxation dynamics of photoexcited carriers in a chemical vapor deposited graphene transferred on quartz substrate are investigated using ultrafast optical-pump terahertz (THz)-probe spectroscopy. Terahertz transmission through graphene sample is reduced by optical pumping. The change of transmission decays exponentially after the optical pulse. We find the decay time is insensitive to the substrate temperatures from 10 K to 300 K, but increases sublinearly with pump flunce. We model the relaxation process involving electron-phonon coupling together with a set of rate equations to describe the transient responses of quasi-particals and optical phonons. We can fit the observered transient terahertz transmission very well. The extracted carrier temperature follows the same trend of decay time as a function of fluence. High pump fluence can significantly increase the carrier temperature and broaden the carrier distributions, consequently causing the reduction of optical phonon emission efficiency and slowing down cooling rate. The differences of our results in comparison to similar measurements of expitaxial graphene on SiC will be disscussed.

11:27AM B6.00002 Raman Spectroscopic Studies of Room-Temperature-Grown Graphene by Plasma-Assisted Chemical Vapor Deposition , CHEN-CHIH HSU, DAVID BOYD, WEI-HSIANG LIN, JONG YEON LEE, NAI-CHANG YEH, Department of Physics, Caltech, Pasadena, CA 91125, USA — We have synthesized graphene using plasma-assisted chemical vapor deposition (CVD) at room temperature (RT). Structural analysis through Raman spectroscopy reveals that high quality large-area graphene can be grown reproducibly. From the frequency shifts of the G-band and 2D-band, it is evident that the average strain of RT-grown graphene becomes much reduced relative to the high-temperature ($1000^{\circ}C$) CVD-grown graphene. This finding is confirmed by the atomically resolved images taken with scanning tunneling microscopy (STM). To investigate the effect of different substrates on the resulting strain in graphene, we have grown graphene on Cu(111) and Cu(100) single crystals and polycrystalline Cu foils. Compared to high temperature CVD-grown graphene, strain is reduced no matter which substrate was used for the RT growth. However, graphene grown on Cu(111) is more inhomogeneous because anisotropic plasma etching of the substrate results in excess steps on the surface and creates stripe-like superstructures in graphene. Upon transferring the RT-grown graphene to SiO2 substrates, we find the average strain minimized. Our results suggest a promising pathway to inexpensive growth of high-quality large-area graphene. This work was supported by NSF through IQIM at Caltech.

11:39AM B6.00003 Carbon atom bonding processes in CVD graphene growth on copper surface: A first principles study[1] , TAKAHISA OHNO, National Institute for Materials Science, University of Tokyo, NOBUO TAJIMA, TOMOAKI KANEKO, JUN NARA, National Institute for Materials Science — Graphene has attracted considerable research interest due to potential application to future electronic devices. Large area and high-quality graphene is needed for device applications. Chemical vapor deposition using copper surface with hydrocarbon source is one of the practical methods to produce graphene. This method is appropriate for creating large area graphene, and the graphene growth control to obtain high quality product is a challenge. The carbon atom nucleation and cluster growth processes in the CVD reactions have been studied extensively as key steps to control graphene growth. In the present study, first principles molecular dynamics calculations are performed to obtain fundamental insight into these C-C bonding process. First principles simulation code PAHSE (http://www.ciss.iis.u-tokyo.ac.jp/english/project/device/) was used in these calculations.

11:51AM B6.00004 Probing dynamics in graphene with infrared spectroscopy[1] , JIE SHAN, Case Western Reserve University — Infrared and far-infrared spectroscopy provides an attractive approach for examining the properties of charge carriers in solids. For the case of graphene, while these possibilities had been recognized, experiments were hindered by the lack of samples of sufficient lateral extent to be probed by standard far-field techniques. Now, with the advent of high-quality graphene grown by chemical vapor deposition (CVD), researchers are able to overcome these limitations. Analysis of optical conductivity by infrared spectroscopy provides direct information about the carrier scattering rate, as well as the intraband and interband transition strength in graphene. Furthermore, when combined with a femtosecond excitation pulse, time-resolved terahertz (or far-infrared) spectroscopy allows us to probe the ultrafast relaxation dynamics of electrons in graphene. In this talk, I will discuss recent results on infrared spectroscopy and dynamics studies of CVD graphene, with an emphasis on identifying the role of electron-phonon and electron-electron interactions and the influence of doping on these interactions.

12:27PM B6.00005 Graphene originated 3D structures grown on the assembled nickel particles , TEREZA PARONYAN, AVETIK HARUTYUNYAN, Honda Research Institute USA Inc., HONDA RESEARCH INSTITUTE USA INC. TEAM — Recently, the fabrication of various morphologies of graphene originated structures became very important due to the perspective of wide range of new applications. Particularly, free standing 3D structured graphene foams could be imperative in energy related areas. Here, we present the new approach of the CVD growth of 3D graphene network by using primarily sintered Ni particle's ($\sim$40μm size) assembles as a template-catalyst via decomposition of low rate of CH_4 at 1100° C based on synthesis method described earlier [1]. SEM and Raman spectra analysis revealed the formation of graphene structure containing a single up to few layers grown on the sintered metal particles served as a catalyst-template. After etching the metal frame without using any support polymer, 3D free-standing graphene microporous structure was formed demonstrating high BET surface area. Two probe measurements of frame resistance were $\sim$2-8Ω. Our approach allows controllable tune the pore size and thereby the surface area of 3D graphene network through the variation of the template-catalyst particles size.

12:39PM B6.00006 Improving the quality of CVD graphene-based devices: synthesis, transfer, fabrication and measurement , JUNJIE WANG, Department of Physics, Penn State University, BEI WANG, Department of Physics, Penn State Univeristy, ANNA SKINNER, Department of Physics, Virginia Tech University, JUN ZHU, Department of Physics, Penn State University — Graphene synthesized by chemical vapor deposition (CVD) is potentially useful in a wide range of electronic and optoelectronic applications. In order to obtain CVD-graphene based devices with performance comparable to their exfoliated counterparts, improvement needs to be made on the synthesis and transfer of graphene, as well as device fabrication and measurement techniques. Here we report on a low-pressure growth procedure, which successfully suppresses the growth of multilayer patches, resulting in large-scale single-layer graphene production. By following the etching of the copper substrate with a HCl/H_2O_2 cleaning step similar to the RCA-2 procedure used in Silicon industry, metal particle contamination is reduced. By applying the gate voltage in pulse, we eliminate the hysteresis commonly observed in the transfer curve of graphene field effect transistors. This allows us to accurately determine the charge neutrality point and carrier mobility of the device. We are able to achieve high-quality CVD-graphene devices with average carrier mobility of 7,000 $cm^2V^{-1}s^{-1}$.

12:51PM B6.00007 Linear magnetoresistance of graphene in contact with inhomogeneous disordered graphitic carbon , JINGLEI PING, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park — We synthesized graphene via chemical vapor deposition(CVD) on platinum foils and transferred graphene to Si_3N_4 membranes for inspection by transmission electron microscope (TEM), or to SiO_2/Si for fabricating field-effect transistors. Dark-field TEM shows that the graphene is decorated with disordered (nanocrystalline) graphitic carbon which is spatially inhomogeneous. The impurity layer can easily be mistaken for a second graphene layer in optical microscopy. Atomic force microscopy shows that impurities form between graphene and Pt, supporting a "growth-from-below" model. The impurity-decorated graphene exhibits linear magnetoresistance (LMR) which is carrier-density-dependent and nonsaturating up to 8 Tesla. No LMR is observed with graphene samples with little impurities, or in exfoliated graphene. We understand the LMR as due to an effective inhomogeneous random-resistor network arising from the spatially inhomogeneous nature of the graphene/impurity system. The results may shed light on the previously-observed LMR in graphene on Si-face SiC.

1:03PM B6.00008 Triggering the Growth of Large Single Crystal Graphene by Chemical Vapor Deposition , TIANRU WU, HAOMIN WANG, GUQIAO DING, DA JIANG, XIAOMING XIE, MIANHENG JIANG, State Key Laboratory of Functional Materials for Informatics, SIMIT, CAS — Graphene, a monolayer of sp2 carbon atoms, has been attracting great interests as an ideal two dimensional crystalline material. Fabrication technique for wafer scale graphene via chemical vapor deposition (CVD) was developed several years ago [1]. However, large scale graphene films from CVD method so far are found to be polycrystalline, consisting of numerous grain boundaries, which greatly degrade the electrical and mechanical properties of graphene [2]. Recently, we obtained hexagonal-shaped single-crystal monolayer graphene domains (∼1.2 mm) [3]. We adapted a strategy to synthesize larger size single crystal grains by regulating the supply of reactants and hytrogen. Nucleation density can be decreased to less than 1000 nuclei /m2. Gradually increase in the supply of reactants could break the equilibrium of growth and etching at the edge of hexagonal-shaped graphene grains. It drives the reaction toward quick growth of graphene domains during the whole CVD process. The graphene grains we obtained show high crystalline quality with high mobility of ∼13000 cm2V-1s-1, which is comparable to that of exfoliated graphene. The results achieved will definitely benefit for further practical application of graphene electronics. [1] Li X S, et al. Science, 2009, 324: 1312∼1314. [2] Huang PY, et al. Nature 2011, 469: 389-392. [3] Wu T R, et al. Adv. Func. Mater. 2012, Doi: 10.1002/adfm.201201577.

1:15PM B6.00009 Superior properties of plasma-assisted room-temperature-grown graphene from STM studies , M.L. TEAGUE, W.-H. LIN, D.A. BOYD, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, Y.-Y. LO, C.-I. WU, Dept. of Elec. Eng., National Taiwan Univ., Taipei, Taiwan, W.-Y. CHAN, W.-B. SU, C.-S. CHANG, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan — We report scanning tunneling microscopic and spectroscopic (STM/STS) studies of large-area monolayer graphene grown at room temperature (RT) on Cu foils, Cu (100) and Cu (111) single crystals, and compare the properties of these samples with high-temperature (1000 °C) CVD-grown graphene. All RT-grown graphene exhibit highly ordered honeycomb structures over ~ 1 cm^2 areas, smooth surface morphology, much reduced strain ($< 0.1\%$) and additional Moire patterns for samples grown on single crystals. The structural quality and reduced strain obtained from STM studies are consistent with finds from Raman spectra. In contrast, high-temperature CVD-grown graphene revealed strongly distorted atomic structures and large strain, giving rise to giant pseudo-magnetic fields and charging effects as manifested by the conductance peaks at quantized energies and the strongly enhanced local conductance in highly strained regions. These strain-induced effects are believed to be responsible for the reduced electrical mobility in typical CVD-grown graphene. The superior structural and electronic properties demonstrated by our RT-grown graphene are promising for a wide range of applications. This work was supported by NSF through IQIM at Caltech.

1:27PM B6.00010 Structural and Electrical Properties of CVD and PECVD Grown Graphene , MICHELLE LANGHOFF, Missouri State University, Springfield, MO 65897, W. MITCHEL, Air Force Research Laboratory, AFRL/RXA, WPAFB, OH, E. GALLO, G. TOMPA, N. SBROCKEY, T. SALAGAJ, Structured Materials Inc, Piscataway NJ 08854, K. GHOSH, Missouri State University, Springfield, MO 65897 — There is a robust research effect on graphene due to its unique properties. While the ultimate goal of this research is to study the electrical properties of graphene, a multistep process of research is require to reach the point at which it is possible to make the necessary measurements. Graphene is typically grown using CVD on a copper substrate: this substrate has been found to offer the best results to date. Unfortunately, this requires the transfer to alternate, non-conducting, substrates in order to effect electrical measurements. This work seeks to determine the optimal transfer process of graphene using Raman spectroscopy and analyzing the prominence of the defect peak. Upon the success of the transfer, electrical properties are evaluated using AFM. This work will discuss the difference in growth quality between standard CVD growth and PECVD, evaluate the success of transfer to alternate substrates, and provide results from preliminary electrical measurements using AFM. We would like to acknowledge Structured Materials Industries Inc. for providing graphene samples.

1:39PM B6.00011 Catalyst-free growth of nanographene and its application , DONGXIA SHI, WEI YANG, DONGHUA LIU, RONG YANG, GUANGYU ZHANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — A new method was developed to synthesis graphene films on various substrates without catalyst at low temperature, which was performed using our home-made remote plasma enhanced chemical vapor deposition system (r-PECVD). The fabricated graphene film is composed of nanographene islands with hexagonal shape and size of several hundred nanometers. Through the adjustment of temperature, the nucleation and growth were fully controlled, in this way, nanographene films with expected crystal size and layers can be obtained. Furthermore, the fabricated nanographene films was also investigated in strain sensors, which shows ultra-sensitive properties with the highest gauge factor over 300 so far for graphene-based strain sensors. The piezoresistive characteristics of nanographene films are based on charge tunneling from neighboring nanographene islands. Besides strain sensors, this simple and scalable graphene fabrication also provides a potential way in many applications fields, such as electrode materials, transparent conductive films, thin film resistors, gas sensors and so on.

1:51PM B6.00012 Engineering epitaxial graphene with oxygen[1] , AMINA KIMOUCHE, SYLVAIN MARTIN, CLEMENS WINKELMANN, OLIVIER FRUCHART, HERVÉ COURTOIS, JOHANN CORAUX, Institut NEEL, CNRS & UJF Grenoble, HYBRID SYSTEM AT LOW DIMENSION TEAM — Almost free-standing graphene can be obtained on metals by decoupling graphene from its substrate, for instance by intercalation of atoms beneath graphene, as it was shown with oxygen atoms [1]. We show that the interaction of oxygen with epitaxial graphene on iridium leads to the formation of an ultrathin crystalline oxide extending between graphene and the metallic substrate via the graphene wrinkles. Graphene studied in this work was prepared under ultra-high vacuum by CVD [2,3]. The samples were studied by combining scanning probe microscopy (STM, AFM) and spatially resolved spectroscopy (Raman, STS). The ultrathin oxide forms a decoupling barrier layer between graphene and Ir, yielding truly free-standing graphene whose hybridization and charge transfers with the substrate have been quenched [4]. Our work presents novel types of graphene-based nanostructures, and opens the route to the transfer-free preparation of graphene directly onto an insulating support contacted to the metallic substrate which could serve as a gate electrode. 2:03PM B6.00013 Graphene growth using Pulsed Laser Deposition , GAUTAM HEMANI, MANUEL QUEVEDO-LOPEZ, MASSIMO V. FISCHETTI, University of Texas at Dallas — To obtain improved electrical performance in graphene, an unconventional growth process using pulsed laser deposition (PLD) where graphene is grown directly on a silicon substrate is proposed. Using PLD, graphene was grown directly on device quality wafer using nickel metal and then characterized with Raman spectroscopy. Also, the Electron Backscatter Diffraction technique was used to characterize the grain structure of the Nickel after deposition in order to understand how the high temperatures affected the graphene growth process. Attempts have also been made to integrate this unconventional growth with standard semiconductor device fabrication in order to explore transfer free graphene based devices. Raman spectroscopy revealed that we have well defined spectra indicating from monolayer to few layer graphene, with minimum defects.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B7 DMP: Focus Session: Graphene Devices II 303 - Arthur Hebard, University of Florida

11:15AM B7.00001 Tunnel magnetoresistance of magnetic junctions based on side-wall epitaxial graphene nanoribbons , CHAO HUAN, JOHN HANKINSON, WENLONG YU, RUI DONG, JAMES PALMER, OWEN VAIL, MING RUAN, School of Physics, Georgia Institute of Technology, CLAIRE BERGER, Gatech - School of Physics, CNRS-Institut Neel, EDWARD CONRAD, WALTER DE HEER, ZHIGANG JIANG, School of Physics, Georgia Institute of Technology — We report on tunnel magnetoresistance (TMR) measurements of magnetic tunnel junctions consisting of cobalt, aluminum oxide barrier, and side-wall epitaxial graphene nanoribbons (GNRs). We find that the measured resistance of tunnel junctions exhibits a spin switch behavior when the magnetic field is applied parallel to the cobalt electrode and sweeping between 1 T and -1 T. This observation indicates that the side-wall GNR is magnetic, with a spin component either parallel or antiparallel with respect to the magnetization direction of cobalt. The largest relative change of TMR observed is about 9% at 6.6 K, corresponding to 14% of spin polarization in GNR. In addition, we find that Rashba effect may play an important role in polarizing the electron spins in GNR; the required electric field could be due to the charge transfer between the carbon atoms on the edge of GNR and the Si atoms of the SiC substrate.

11:27AM B7.00002 Superconductor-graphene based quantum entangler, a progress report , IVAN BORZENETS, YUYA SHIMAZAKI, JUERGEN SAILER, The University of Tokyo, RUSSELL DEACON, Riken, MICHIHISA YAMAMOTO, SEIGO TARUCHA, The University of Tokyo — We report on the progress in fabricating a functioning quantum entangler. The device is based on the cooper-pair splitter "T" junction with either lead (Pb) or niobium (Nb) acting as the superconductor and graphene acting as the normal metal. Unlike the typically used aluminum (Al), lead and niobium have a superconducting transition at much higher temperatures (meaning a higher superconducting gap Δ), thus increasing the extent of the proximity effect. Proper techniques had to be developed in order to create transparent, superconductivity inducing contacts to graphene; and graphene-based Josephson junctions were fabricated and characterized. Meanwhile, graphene features high mobility, and therefore a high coherence length. We have patterned graphene into constrictions resulting in individually gated quantum dots with consistent characteristics. This is required in order to prevent both electrons from the same cooper pair from traveling into a single normal lead.

11:39AM B7.00003 C-axis magnetoresistance in epitaxially grown multilayer graphene , SRIKRISHNA BODEPUDI, ABHAY SINGH, SANDIPAN PRAMANIK, University of Alberta — Magnetoresistance, the change in electrical resistance of a solid-state system as a function of an external magnetic field, is a key effect in condensed matter physics both for fundamental understanding of charge transport phenomena as well as immense commercial implications. Artificial layered structures, such as metallic or metal-insulator multilayers often exhibit "giant magnetoresistance" or "tunnel magnetoresistance" effects that are exploited in various state-of-the-art data storage and magnetic field sensing devices.. Graphite is a naturally occurring layered structure in which graphene layers are stacked up on each other. Magnetoresistance in graphitic systems has drawn significant attention in recent years due to the unique crystal structures of these materials, which often lead to novel physics. In this work we consider epitaxial multilayer graphene on nickel and studied c-axis charge transport when the magnetic field is applied normal to the graphene plane. We show that the electrical resistance measured across the graphene stack on nickel can be reduced by two orders of magnitude by applying a relatively small magnetic field of few kilogausses normal to the layer plane. This feature persists even at room temperature and is far stronger than any other magnetoresistance effect reported to date for comparable temperature and field conditions. Existence of such effect makes multilayer graphene an attractive platform for magnetic field sensing, data storage and exploration of fundamental insights into graphene physics.

11:51AM B7.00004 Graphene barristor for high performance devices , JINSEONG HEO, Samsung Advanced Institute of Technology — Graphene has unique properties, such as work-function tunability and high intrinsic mobility. Recently, we have introduced a new concept device, a graphene variable-barrier "barristor" (GB), based on those properties. In this presentation, I will describe the three-terminal active device, GB, where the key is an atomically sharp interface between graphene and hydrogenated silicon surface. Large modulation on the device current, on/off ratio of 100000, is achieved by adjusting the gate voltage to control the Schottky barrier between graphene and silicon. The barrier height was tuned to 0.2 electron volts by adjusting graphene work function which results in large shifts of diode threshold voltages. For logic application, an inverter and a half-adder were demonstrated using the complementary GB's on 150-mm wafers. In addition, recently developed vertical transistor based on asymmetric junctions will be discussed.

12:27PM B7.00005 Gate Tunable Graphene-Silicon Ohmic/Schottky Contact , CHUN CHUNG CHEN, CHIA CHI CHANG, ZHEN LI, ANTHONY LEVI, STEVE CRONIN, University of Southern California — We have recently demonstrated gate tunable graphene-silicon Schottky diodes, in which the low bias conductance can be varied by more than three orders of magnitude [1,2]. Here, we deposit graphene on silicon substrates and observe the rectifying $I-V$ characteristics in graphene-silicon junctions, indicating the formation of Schottky junction due to the mismatch of their work functions. By applying a polymer electrolyte gate to the graphene surface, the Fermi energy of the graphene can be shifted $\pm$ 0.85eV from its charge neutrality point (-4.6eV) to match the conduction (-4.01eV) or valence band (-5.13eV) of silicon to reduce the Schottky barrier and result in Ohmic contacts with both n- and p-type silicon. The $I-V$ characteristics observed under light illumination also indicate that the short circuit current can be increased or decreased by varying graphene-silicon work function difference, further demonstrating that the graphene-silicon junction and be changed between Schottky and Ohmic contact.

12:39PM B7.00006 Hole Injection from Silicon to Oxide Using Graphene as Transparent Electrode , RUSEN YAN, NIST; University of Notre Dame, HUILI G. XING, University of Notre Dame, NHAN VAN NGUYEN, NIST — We demonstrate a novel application of graphene as a transparent electrode in internal photoemission (IPE) spectroscopy. Owing to its low absorption in the IR/Visible/UV range, graphene enables the direct observation of hole injection, and thus the measurement of both conduction and valence band offsets at the semiconductor-oxide hetero-interface. The photocurrents, consisting of electron or hole transitions between Si substrate and graphene as a function of incident photon energy under various applied gate voltage are measured. The barrier height is further determined from the photoemission quantum yield, which is defined as the ratio of photocurrent and light intensity. As a result, the barrier heights, φ_e^0, from the valence band top in Si to the bottom of the conduction band in Al_2O_3, and φ_h^0, from the bottom of the conduction band in Si to the top of the valence band in Al_2O_3 are extracted to be 3.5 eV and 4.1 eV, respectively. Furthermore, the bandgap of Al_2O_3 can be simply obtained by$E_g^{Al_2O_3} = \phi_e + \phi_h - E_g^{Si} = 3.5 + 4.1 - 1.1 = 6.5$eV, close to previously reported values. Similar phenomenon is also observed and confirmed by replacing Al_2O_3 with 10 nm SiO_2.

12:51PM B7.00007 Thin film barristor: a gate tunable vertical graphene-pentacene-gold device , CLAUDIA OJEDA-ARISTIZABAL, WENZHONG BAO, MICHAEL S. FUHRER, Center for Nanophysics and Advanced Materials University of Maryland, College Park — Graphene, a one atom thick crystal made of carbon, shows exciting possibilities as a tunable electrode for semiconductors. Graphene's electrochemical potential can be tuned over a span of electron volts, and graphene is expected to have no interface states. Here we explore graphene as a tunable electrode contacting pentacene, a van der Waals molecular semiconductor which should also have no interface states. We fabricate a vertical thin-film barristor device consisting of highly doped silicon (gate), 300 nm SiO_2 (gate dielectric), monolayer graphene, pentacene, and gold top electrode. During fabrication an intermediate layer of SiO_2 is deposited over the graphene leaving a small hole for the pentacene contact, insuring vertical transport. We show that the current across the device is modulated by the Fermi energy level of graphene, tuned with an external gate voltage. We interpret the device current within thermionic emission theory.

1:03PM B7.00008 First-Principles Study of Contact Resistance between Graphene and Metal Electrodes[1] , TOMOAKI KANEKO, Computational Materials Science Unit, NIMS, TAKAHISA OHNO, Computational Materials Science Unit, NIMS, Institute of Industrial Science, University of Tokyo — Graphene attracts much interest for post-silicon electronics material due to its outstanding electronic transport properties such as considerably high mobility at room temperature. For the application of electronics devices, contacting of metal electrodes is necessary and decreasing of contact resistance between graphene and the metal electrodes is regarded as one of a key issue. In this study, we investigate the contact resistance using DFT+NEGF method. We consider the Ni and Cu electrode within LDA and TM-type norm-conserving pseudo-potential. We employed PHASE code [1] to determine the interface structures. Then, we constructed two terminal device structures in which current flows from metals to graphene. The electron transport properties were calculated using ASCOT code[2]. For Ni electrode, the dependence of the electrode size qualitatively agrees well with that obtained by the experiments. But our results suggest that contact resistance can be reduced considerably. [1] http://www.ciss.iis.u-tokyo.ac.jp/english/project/device/. [2] H. Kondo, J. Nara, H. Kino and T. Ohno, Jpn. J. Appl. Phys. 47, 4792 (2008).

1:15PM B7.00009 ABSTRACT WITHDRAWN –

1:27PM B7.00010 A 1D wide band gap graphene metal-semiconductor-metal junction for devices[1] , MEREDITH NEVIUS, JEREMY HICKS, Georgia Institute of Technology, ANTONIO TEJEDA, Synchrotron SOLEIL,Institut Jean Lamour, CNRS - Univ. de Nancy - UPV-Metz, AMINA TALEB-IBRAHIMI, UR1 CNRS/Synchrotron SOLEIL, FENG WANG, EDWARD CONRAD, Georgia Institute of Technology — Despite many advances in understanding graphene physics, progress towards a working, reproducible graphene-based switch has been nearly stagnant. Mastering obstacles like lithographic limitations, process-induced disorder, scalability, and reproducibility is absolutely crucial. We have successfully grown graphene over patterned steps on silicon carbide and, using angle resolved photoemission spectroscopy, have discovered a one-dimensional metal-semiconducting-metal junction made completely from graphene. The junction is created by inherent graphene-substrate interactions as the graphene grows over the patterned steps. The semiconducting graphene strip is connected on either side by metallic graphene sheets and has a band gap of greater than 0.5 eV.[REF] In addition, experimental results show that the average electronic band structure of thousands of ribbons varies very little even on length scales of tens of microns. We will present results on the growth of these graphene structures along with angle resolved photoemission spectroscopy measurements that reveal the band structure of both the graphene ribbons on the step facets and the 1D semiconducting strip. REF Nature to be published

1:39PM B7.00011 Probing Klein tunneling through angle dependence of resistance across graphene p-n junctions[1] , ATIKUR RAHMAN, JANICE WYNN GUIKEMA, NINA MARKOVIC, Johns Hopkins University — We have studied the angle-dependent resistance characteristics of "Y"-shaped dual-gated graphene p-n junction devices. Different arms of each device share a common top gate, and the branching of current in the arms at different angles is determined by the transparency of p-n junctions formed under the top gate. For a particular back gate and top gate voltage, we first balanced the voltage drop in the straight and angled arms, and then we studied the variation of the resistance as a function of top gate keeping the back gate voltage fixed. Deviation from the balanced condition with varying top gate voltage measures the transparency of the p-n junctions in the arms. We found that this deviation is large for a p-n*-p or n-p*-n configurations, as compared to p-p*-p or n-n*-n junctions, which provides a direct evidence of the angle-selective transmission of charge carriers in graphene p-n junction.

1:51PM B7.00012 Chemically functionalized graphene for bipolar electronics[1] , BERNARD MATIS, National Research Council/Naval Research Laboratory, JEFFREY BALDWIN, BRIAN HOUSTON, Naval Research Laboratory, NAVAL RESEARCH LABORATORY TEAM — We discuss the use of chemical functionalization, in particular hydrogenation, to achieve control of the local carrier type and density in graphene, which is a prerequisite for the development of graphene-based bipolar electronics. Transport measurements are used to demonstrate independent carrier types and densities within adjacent semi-metallic graphene and semiconducting hydrogenated graphene regions. Measurements of the Hall coefficient confirm that the graphene and hydrogenated graphene charge carriers change sign about the charge neutrality point, that the graphene carrier density retains its linear dependence on a back gate voltage, and reveal that the hydrogenated graphene carrier density deviates from such a linear relationship. Measurements across the bipolar interface reveal an increasing resistance for higher hydrogen concentrations and a source of constant resistance across a range of back gate voltages for lower hydrogen concentrations.

2:03PM B7.00013 Resist-free graphene/metal interaction extracted through quantum capacitance measurement , R. IFUKU, K. NAGASHIO, T. NISHIMURA, A. TORIUMI, Department of Materials Engineering, Univ. of Tokyo — Understanding of the graphene/metal interaction is crucially important from both scientific and practical viewpoints. In the electric device structure, it is reported that graphene under the metal electrodes maintains the linear dispersion regardless of kinds of metals. In case of graphene grown on metals, on the other hand, the modulation of the linear dispersion strongly depends on kinds of metals, e.g. band modulation occurs on Ni and not on Au. The key issue to elucidate this discrepancy can be the resist residual in the device fabrication process. In this study, the resist-free graphene/metal interaction was studied from the density of states (DOS)–energy relation determined by the quantum capacitance measurement of metal/graphene/SiO_2/n^+-Si stack. Graphene in resist-free contact with Au maintains the linear DOS-energy relation, except near the Dirac point. Graphene contacting Ni shows larger DOS at the Dirac point, resulting in limited gate modulation of E_F in graphene. Resist free process reveals the intrinsic difference in the strength of the graphene/metal interaction (π-d coupling or van der Waals) for Ni and Au.

Session B8 DMP: Focus Session: Hexagonal BN, Graphene, and Graphene Oxide Synthesis I

307 - Mauricio Terrones, Pennsylvania State University

11:15AM B8.00001 TBD , PULICKEL AJAYAN, Rice University — No abstract available.

11:51AM B8.00002 Molecular beam growth of sub-monolayer and multilayer graphene on h-BN flakes[1] , LARA FERNANDES DOS SANTOS, SHENG WANG, ULRICH WURSTBAUER, Columbia University, NY, JORGE M. GARCIA, Instituto de Microelectronica de Madrid, CNM, CSIC, Spain, LEI WANG, ANTONIO LEVY, JUNGSIK PARK, CORY RAYMOND DEAN, Columbia University, NY, LOREN N. PFEIFFER, Princeton University, NJ, JAMES HONE, ARON PINCZUK, Columbia University, NY — We report the successful growth of graphene layers on h-BN substrate flakes in a MBE environment. The growth configuration was designed to allow a gradient in the deposition rate (DR) of carbon on the substrate. The growth conditions such as the substrate temperature were highly controlled. Characterization is carried out by spatially resolved Raman spectroscopy and by AFM imaging. We investigated the graphene coverage on the h-BN flakes. The flakes could be partially covered by a sub-monolayer film, fully covered by a single layer or fully covered by a multilayer film. We find high quality graphene in sub-monolayer and single layer growths. We found a striking independence on the carbon DR, which is attributed to the high mobility of carbons atoms on the h-BN surface. This is a characteristic feature of van der Waals molecular beam growth.

12:03PM B8.00003 Synthesis and Characterization of Large-Area Graphene Directly CVD-Grown on h-BN[1] , MINWOO KIM, YOUNG JAE SONG, MIN WANG, SEONG-KYU JANG, SUNGJOO LEE, SKKU Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University (SKKU), Suwon 440-746, Korea, WON-JUN JANG, SE-JONG KAHNG, Department of Physics, Korea University, Seoul 136-713, Korea, GRAPHENE SYNTHESIS COLLABORATION, CHARACTERIZATION COLLABORATION — As an ideal substrate for graphene, hexagonal boron nitride (h-BN) has been utilized and studied extensively by transfer technique, which still has a high chance to have impurities at the graphene/h-BN interface. Here we report direct CVD growth of graphene on large area h-BN film. AFM and Raman spectroscopy measurements show that there is only one monolayer of graphene, and whose unperturbed electronic structures are also confirmed by electron transport measurements and scanning tunneling spectroscopy. High resolution TEM images for cross-section taken before and after transferring graphene/h-BN on to SiO2 indicate this CVD-grown hybrid structure is robust enough. Based on this new method, high quality and large area graphene on h-BN film with a clean interface can be synthesized for the application of electronic devices, and can fill the missing steps to grow fully CVD-grown super-structure of graphene and h-BN.

[1]This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (Grant Numbers: 2009-0083540, 2012R1A1A2020089 and 2012R1A1A1041416).

12:15PM B8.00004 Initial Growth of h-BN , CHANYONG HWANG, E.K. SEO, JUN PARK, WONDONG KIM, INHO LEE, Korea Research Institute of Standards and Science — Recently h-BN has drawn a lot of attention due to its use as an insulating layer for graphene application. Its growth on several transition metal surfaces such as Ni has been focused on their local atomic structure and superstructure formed on surfaces. However, the growth of h-BN in a large has not been studied so far. We found very interesting growth mode of h-BN on Cu surface. The shape of island is strongly dependent on the orientation of the Cu surface, which is quite different from that of the graphene on Cu. Based on the growth model, a fairly large grain size of h-BN(order of 0.1 mm) can be made. More detailed process on the growth of h-BN will be discussed.

12:27PM B8.00005 In-situ detection of nano-crack of graphene using polarized optical microscopy , JONG-HYUN AHN, School of Advanced Materials Science and Engineering, Sungkyunkwan University and School of Electrical and Electronic Engineering, Yonsei University — Recent works for producing large-area, high quality graphene films through chemical vapor deposition (CVD) and transferring them onto various large-area substrates have offered the possibility of their use as transparent conductive films in various optoelectronic devices. However, various kinds of defects such as pinhole, nano-crack and grain boundaries incorporated for CVD growth process or transfer process of graphene to target substrates degrade the electrical and mechanical performance, which limit the quality needed for the practical use of graphene films. In particular, knowledge of the mechanism of defect generation in graphene under high strain is important to apply graphene in flexible and stretchable electronic devices. Therefore, various methods have been studied to understand the mechanism of defect generation and observe such defects directly. For example, microscopic tools such as TEM, AFM and STM have a way to observe grain boundaries and defects of graphene. However, these methods have drawbacks such as requirement of a complicated sample preparation, a time delay and limited size of observation. In this talk, we present in situ visualization method to identify the distribution of defects in graphene such as pinhole and crack created by growth and transfer process. In addition, we suggest the alignment of liquid crystal molecules on graphene shows strong correlation with domain size of graphene.

1:03PM B8.00006 Enhanced catalytic reactivity of graphene and h-BN by selective substitution , JUNHAO LIN, BIN WANG, SOKRATES PANTELIDES, Physics department, Vanderbilt University — Recent experiments have demonstrated that nitrogen-doped graphene is an efficient metal-free catalyst for the oxygen reduction reaction in fuel cells, but the underlying mechanism still needs to be explored. Using first-principles calculations, we find that in N-doped graphene oxygen molecules can only dissociate at carbon atoms surrounded by nitrogen. We attribute the enhanced chemical reactivity of these carbon atoms to the strong localized states near the Fermi level, which results from misalignment of pz orbitals of nitrogen and carbon atoms. We further show that the dissociation of oxygen molecules can also occur in hydrogenated graphene and h-BN based on the same mechanism. Therefore, we propose a generic way for functionalization of graphene to achieve enhanced catalytic reactivity.

1:15PM B8.00007 CVD graphene growth via magnetic inductive heating of metal substrates[1] , RICHARD PINER, HUIFENG LI, XIANGHUA KONG, LI TAO, JONGHO LEE, DEJI AKINWANDE, RODNEY RUOFF, University of Texas at Austin — A new route to the CVD synthesis of graphene with inductive heating of metal substrates is presented. The design and implementation of a new type of reactor that uses magnetic induction to heat metal substrates is presented. The advantages of this reactor and important parameters for the successful growth of high quality graphene or few layer graphene will be presented. Optical and SEM images, Raman spectra, and electron and hole mobility will be presented and compared to results for more traditional CVD methods

[1]We wish to thank W.M. Keck foundation for support.

1:27PM B8.00008 Synthesis of Large-grain, Single-crystalline Monolayer and AB-stacking Bilayer Graphene , LUYAO ZHANG[1], YUNG-CHEN LIN, YI ZHANG, HAN-WEN CHANG, WEN-CHENG YEH, CHONGWU ZHOU, University of Southern California, USC NANOTECHNOLOGY RESEARCH LABORATORY TEAM — We report the growth of large-grain, single-crystalline monolayer and AB-stacking bilayer graphene by the combination of ambient pressure chemical vapor deposition and low pressure chemical vapor deposition. The shape of the monolayer graphene was modified to be either hexagons or flowers under different growth conditions. The size of the bilayer graphene region was enlarged under ambient pressure growth conditions with low methane concentration. Raman spectra and selected area electron diffraction of individual graphene grain indicated that the each graphene grain is single-crystalline. With electron beam lithography patterned PMMA seeds, graphene nucleation can be controlled and graphene monolayer and bilayer arrays were synthesized on copper foil. Electron backscatter diffraction study revealed that the graphene morphology had little correlation with the crystalline orientation of underlying copper substrate.

[1]Mork Family Department of Chemical Engineering and Materials Science

1:39PM B8.00009 CVD growth of large-grain graphene on Cu(111) thin films , DAVID L. MILLER, KYLE M. DIEDERICHSEN, MARK W. KELLER, National Institute of Standards and Technology, Boulder, CO — Chemical vapor deposition of graphene on polycrystalline Cu foils has produced high quality films with carrier mobility approaching that of exfoliated graphene. Growth on single-crystal films of Cu has received less attention, despite its potential advantages for graphene quality and its importance for eventual applications. This is likely due to the difficulty of obtaining large ($\geq$ 1 mm) grains in Cu thin films, as well as dewetting and roughening of Cu films at temperatures near the Cu melting point (1084 C). We found that 450 nm of Cu(111), epitaxially grown by sputtering onto Al_2O_3(0001), formed $>$ 1 mm grains when annealed at 1065 C for 40 minutes in 40 Torr of Ar and 2.5 mTorr of H_2. After this annealing, adding 3 mTorr of CH_4 for 8 minutes produced a monolayer graphene film covering $> 99\%$ of the Cu surface. Stopping growth after 4 minutes produced dendritic graphene islands with 6-fold symmetry and diameter of 20 μm to 100 μm. After growth, the Cu film remained smooth except for thermal grooving at grain boundaries and a few holes of diameter $\approx$ 10 μm where Cu dewetted completely ($\approx$ 10 holes on each 5 mm x 6 mm chip).

1:51PM B8.00010 Drastic reduction in the growth temperature of graphene on Cu substrates via enhanced London dispersion force , JIN-HO CHOI, ZHANCHENG LI, PING CUI, XIAODONG FAN, CHANGGAN ZENG, ZHENYU ZHANG, University of Science and Technology of China — London dispersion force is ubiquitous in nature, and is increasingly recognized to be an important factor in a variety of surface processes. Here we demonstrate unambiguously the decisive role of London dispersion force in non-equilibrium growth of ordered nanostructures on metal substrates using aromatic source molecules. Our first-principles based multi-scale modeling shows that a drastic reduction in the growth temperature, from $\sim$1000 °C to $\sim$300 °C, can be achieved in graphene growth on Cu(111) when the typical carbon source of methane is replaced by benzene or p-Terphenyl. The London dispersion force enhances their adsorption energies by about (0.5-1.8) eV, thereby preventing their easy desorption, facilitating dehydrogenation, and promoting graphene growth at much lower temperatures. These quantitative predictions are validated in our experimental tests. The general trends established are also applicable in graphene growth using other aromatic carbon sources, and more broadly in molecular assembly and synthesis of surface-based nanostructures.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B9 FIP: Invited Session: FIP Symposium on the Science of Climate 308 - Eugene Chudnovsky, City University of New York - Lehman College

11:15AM B9.00001 Climate Concerns: Asking the Right Questions , RICHARD LINDZEN, Massachusetts Inst of Tech-MIT — No abstract available.

11:51AM B9.00002 Solar Variability and Climate Change , JOANNA HAIGH, Imperial College London UK — The need to distinguish natural from anthropogenic causes of climate change makes it important to understand and quantify any impact of the Sun. In this talk I will outline what is known about variations in solar output and review the evidence for solar influences on climate over a range of timescales. When the Sun is more active our work shows the response in temperature is not a warming of the tropics but mainly of mid-latitudes, along with a weakening and poleward shift of the jet streams and storm-tracks. Using climate models we have found that an important factor driving this response is the absorption in the stratosphere of solar UV radiation and we have identified a dynamical coupling mechanism which transfers a solar signal from the stratosphere to the atmosphere below. This means that simple assessments of the solar impact based on energy balance ideas may be effective in estimating global mean temperature change but might be neglecting important effects on regional climate. During the last solar cycle minimum the Sun was in a state of very low activity and some satellite measurements have suggested that the solar spectrum has been behaving in a strange and unexpected way. The talk will finish with a discussion of recent work on the implications of these spectral variations.

12:27PM B9.00003 On Winning the Race for Predicting the Indian Summer Monsoon Rainfall[1] , BHUPENDRA NATH GOSWAMI, Indian Institute of Tropical Meteorolgy, Pune — Skillful prediction of Indian summer monsoon rainfall (ISMR) one season in advance remains a "grand challenge" for the climate science community even though such forecasts have tremendous socio-economic implications over the region. Continued poor skill of the ocean-atmosphere coupled models in predicting ISMR is an enigma in the backdrop when these models have high skill in predicting seasonal mean rainfall over the rest of the Tropics. Here, I provide an overview of the fundamental processes responsible for limited skill of climate models and outline a framework for achieving the limit on potential predictability within a reasonable time frame. I also show that monsoon intra-seasonal oscillations (MISO) act as building blocks of the Asian monsoon and provide a bridge between the two problems, the potential predictability limit and the simulation of seasonal mean climate. The correlation between observed ISMR and ensemble mean of predicted ISMR (R) can still be used as a metric for forecast verification. Estimate of potential limit of predictability of Asian monsoon indicates that the highest achievable R is about 0.75. Improvements in climate models and data assimilation over the past one decade has slowly improved R from near zero a decade ago to about 0.4 currently. The race for achieving useful prediction can be won, if we can push this skill up to about 0.7. It requires focused research in improving simulations of MISO, monsoon seasonal cycle and ENSO-monsoon relationship by the climate models. In order to achieve this goal by 2015-16 timeframe, IITM is leading a Program called Monsoon Mission supported by the Ministry of Earth Sciences, Govt. of India (MoES). As improvement in skill of forecasts can come only if R & D is carried out on an operational modeling system, the Climate Forecast System of National Centre for Environmental Prediction (NCEP) of NOAA, U.S.A has been selected as our base system. The Mission envisages building partnership between operational forecasting agency and National and International R & D Organizations to work on improving modeling system. MoES has provided substantial funding to the Mission to fund proposals from International R & D Organizations to work with Indian Organizations in this Mission to achieve this goal. The conceptual framework and the roadmap for the Mission will be highlighted.

[1]Indian Institute of Tropical Meteorology is funded by Ministry of Earth Sciences, Govt. of India.

1:03PM B9.00004 Stratospheric ozone: a major (long neglected) anthropogenic forcing of the climate system , DARRYN W. WAUGH, Department of Earth and Planetary Sciences, Johns Hopkins University — As a consequence of the Montreal Protocol, the depletion stratospheric ozone by CFCs, which occurred primarily in the last decades of the 20th Century, has noticeably slowed down in recent years. For instance, the ozone hole in 2012 has been measured to be the smallest in 20 years. In view of this, it has long been thought that the ozone hole is a "solved problem." What has not been appreciated until very recently is that the large man-made perturbation of stratospheric ozone has had profound consequences on the climate system in the Southern Hemisphere. In fact, a lot of evidence is now at hand strongly suggesting that ozone depletion, not increasing greenhouse gases, have been been the major driver of observed atmospheric circulation changes in the Southern Hemisphere in the second half of the 20th Century. Furthermore, climate models robustly show that the closing of the ozone hole in the next half century will actually oppose the impact of increasing greenhouse gases, and project large cancellations between these two anthropogenic forcings resulting in greatly reduced future trends in the Southern Hemisphere.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B10 FHP: Invited Session: Celebrating 100 Years of Physical Review at APS 309 - Don Howard, University of Notre Dame

11:15AM B10.00001 In the Beginning... , MARTIN BLUME, American Physical Society — Physical Review was founded at Cornell University in 1893, by two professors, Edward L. Nichols and Ernest Merritt. Both were educated in Germany, and were familiar with the differences in publications abroad. They were enthusiastic about the idea of an American publication devoted entirely to physics. They fortunately had the full support of the then President of Cornell, J. Gould Shurman, who arranged for an initial grant of $500, and eventually, for a first year total of $2500. The founding editors were soon joined by Frederick Bedell, who remained an Editor into the 1920's. This talk will follow the progress (and otherwise) of the journal through the formation of the American Physical Society in 1899 and the transfer of its operation from Cornell to the APS in 1913.

11:51AM B10.00002 The American Reception of the Quantum as Seen by the Physical Review, 1900-1927 , ROBERT CREASE, Stony Brook University — This talk tells the story of the "American awakening" to quantum theory seen through the pages of the *Physical Review*. It begins with the journal's first mentions of Planck and the quantum, follows the story through publication of the first papers on experiment and theory, and concludes just after Schrödinger's 1926 *Physical Review* article on wave mechanics – which reflected the Austrian physicist's realization that at last there existed a large enough American audience interested in theoretical developments of quantum mechanics to make such an article worth writing and publishing.

12:27PM B10.00003 "Your Most Distinguished Contributor": Einstein and the Physical Review , DANIEL KENNEFICK, University of Arkansas, Fayetteville — Einstein began to publish in the Physical Review after he began working with his first American research assistant, Nathan Rosen. They submitted three landmark papers together to the journal. These papers and their reception are discussed, along with the remarkable story of Einstein's umbrage at the referee report he received in response to his third submission. Although the referee was vindicated and Einstein eventually had to reverse his position, he never submitted a research paper to the Physical Review again. The identity of the referee, as learned from the Review's own records, will be revealed and Einstein's subsequent relationship with the journal will be discussed.

1:03PM B10.00004 Bringing the Physical Review into the Digital Age , MARK DOYLE, American Physical Society — Efforts to make the entire contents of the Physical Review available digitally began early in the 1990's and closely tracked the development of the World Wide Web itself. Not satisfied with just publishing electronic versions of newly published material, the APS also embarked on one of the first systematic digitizations of the entire contents of a major series of journals in any discipline. While all APS journals were online by 1997 and the backfile archive was completed in early 2002, the journals have continued to grow and adapt as the digital environment has matured. This talk will give an account of the evolution of APS journals through the digital transition, from boxes of backup tapes to the full-fledged, invaluable online resource it is today.

1:39PM B10.00005 Physical Review: a family of journals , GENE SPROUSE, Editor in Chief, American Physical Society — The expansion of research in physics in the last 100 years has been reflected in the expansion of the Physical Review(PR). Reviews of Modern Physics was the first "new" journal, starting in 1929. Physical Review Letters commenced in 1958, and was the first "letters" type of journal for important new results in all fields. By 1970 the Physical Review itself had grown so large that it was necessary to separate it by field into manageable volumes: PRA, PRB, PRC and PRD, and subsequently PRE, which was split off from PRA. More recently, two Special Topics journals for accelerator physics and physics education were pioneers of the open access business model, and the newest member of the family, Physical Review X, continues this trend. PRX is broad scope and very selective, setting it well above many of the new open access journals with a review standard of "not incorrect." Some possible future directions for the Physical Review journals will be discussed.

Session B11 DPOLY GERA: Invited Session: Polymer Membranes for Clean Energy and Water II 310 - Ali Evern Ozcam, University of California, Berkeley

11:15AM B11.00001 Polymer-Derived Membranes for Large Scale Energy-Efficient Separations , WILLIAM KOROS, Georgia Institute of Technology — A significant fraction of global energy is consumed to meet separation and purification needs of society, since existing processes are based primarily on energy intensive operations such as distillation. In fact, movement to alternative raw material sources tends to increase this consumption, since separation needs are more difficult to meet in such cases. Energy intensity and carbon dioxide emissions associated with many large scale separations can be reduced by a full order of magnitude by substituting membrane processes for traditional thermally-driven separation approaches. This presentation will provide a framework illustrating how such a strategy can be applied. An advanced manufacturing perspective relying upon polymer-derived materials is stressed within this framework.

11:51AM B11.00002 Dramatic nano-fluidic properties of carbon nanotube membranes as a platform for protein channel mimetics[1] , BRUCE HINDS, University of Kentucky — Carbon nanotubes have three key attributes that make them of great interest for novel membrane applications: 1) atomically flat graphite surface allows for ideal fluid slip boundary conditions and extremely fast flow rates 2) the cutting process to open CNTs inherently places functional chemistry at CNT core entrance for chemical selectivity and 3) CNT are electrically conductive allowing for electrochemical reactions and application of electric fields gradients at CNT tips. Pressure driven flux of a variety of solvents (H2O, hexane, decane ethanol, methanol) are 4-5 orders of magnitude higher than conventional Newtonian flow [Nature 2005, 438, 44] due to atomically flat graphite planes inducing nearly ideal slip conditions. However this is eliminated with selective chemical functionalization [ACS Nano 2011 5(5) 3867-3877] needed to give chemical selectivity. These unique properties allow us to explore the hypothesis of producing "Gatekeeper" membranes that mimic natural protein channels to actively pump through rapid nm-scale channels. With anionic tip functionality strong electroosmotic flow is induced by unimpeded cation flow with similar 10,000 fold enhancements [Nature Nano 2012 7(2) 133-39]. With enhanced power efficiency, carbon nanotube membranes were employed as the active element of a switchable transdermal drug delivery device that can facilitate more effective treatments of drug abuse and addiction. Recently methods to deposit Pt monolayers on CNT surface have been developed making for highly efficient catalytic platforms. Discussed are other applications of CNT protein channel mimetics, for large area robust engineering platforms, including water purification, flow battery energy storage, and biochemical/biomass separations.

12:27PM B11.00003 Structure Formation of Block Copolymer Membranes

, VOLKER ABETZ, Institute of Polymer Research, Helmholtz-Zentrum Geesthacht — Isoporous membranes have received increasing attention during the last couple of years. The advantage of these materials is to give access to membranes with a very high number density of pores with controlled diameters, thus leading to ultrafiltration membranes with a very high permeability, and simultaneously also with a very high selectivity in terms of size exclusion. Different approaches have been reported, which typically involve the transfer of a thin block copolymer film from a solid to a porous support, eventually followed by an edging step. An alternative strategy is to form integral asymmetric membranes, where the thin top layer is continuously changing into a spongy support layer, thus avoiding the build-up of mechanical stresses. This happens by subjecting the cast polymer solution film into a precipitant, inducing the so-called phase inversion by exchange of solvent with the non-solvent. Here it is important to have a system where solvent and nonsolvent are fully miscible. This strategy also enables the direct formation of open pores without a subsequent edging step, if the solvents and nonsolvents are appropriately chosen. Different types of amphiphilic block copolymers based on styrene, 2- or 4-vinyl pyridine, and ethylene oxide with various compositions and molecular weights will be discussed. These block copolymers were dissolved at different concentrations in various solvent mixtures, and then cast on a non-woven support, which was either pretreated with a liquid, or not. Varying the time before the cast solution was subjected to phase inversion, as well as choosing the temperature of the precipitation bath, are further parameters having strong influence on the obtained membrane film structure. Membranes with pore forming blocks showing pH or temperature sensitive behaviour can be reversibly switched from an open state to a closed state. The size of the pores can be controlled by both molecular weight and composition of the block copolymers.

1:03PM B11.00004 Scalable Directed Self-Assembly and Anisotropic Transport Properties of Soft Mesophases for Membrane Applications[1]

, CHINEDUM OSUJI, Department of Chemical and Environmental Engineering, Yale University — Self-assembly of block copolymers and surfactant mesophases can be can be utilized in creating composite materials with very fine periodic structures. Easy access to nm-scale features coupled with compositional variety and thus tunable physical properties makes these nanoscale heterogeneous materials excellent candidates for selective transport applications including ion-conduction, ultrafiltration and desalination. A critical limitation in their performance however arises from the tortuosity of randomly oriented self-assembled structures. We show that in appropriately engineered systems, magnetic fields provide a viable route for scalable control of morphology, producing well aligned materials over large length scales. Here we discuss this approach for the fabrication of ion conduction membranes, aligned carbon nanotube membranes and nanoporous films. We quantitatively assess the anisotropic transport properties of one such system and confront the data with models based on effective medium theory and composite conductivity calculations. The results demonstrate that directed self-assembly can provide non-trivial enhancement of the transport properties in these applications.

1:39PM B11.00005 Understanding the Permeation of Solutes in Water Treatment Membranes

, WILLIAM PHILLIP, University of Notre Dame — The responsible management of the world's water resources is essential to supporting human life on earth. The successful development of reverse osmosis seawater desalination makes it a crucial component in the portfolio of water supply options. However, other measures to alleviate the stresses on water supplies are necessary to responsibly and sustainably meet the worldwide demand for fresh water. Osmotically driven membrane processes (ODMP) are an emerging set of technologies that show promise in water conservation and reuse, as well as wastewater reclamation. The majority of research in the field has focused on predicting and enhancing water permeation through membranes, however, the effective operation of ODMP systems requires that the permeation of solutes across water treatment membranes be better understood. For example, the reverse flux of draw solute from the concentrated draw solution into the feed solution should be minimized. Additionally, due to the presence of solute-solute interactions that arise because of the unique geometry of ODMPs, the rejection of dilute solutes in these processes can be dramatically different than those observed in traditional pressure driven operations. In this talk, theoretical and experimental approaches are used to explore the permeation of solutes in osmotically driven membrane processes. Phenomenological models were developed that describe the forward and reverse permeation of the solutes across an asymmetric membrane in forward osmosis operation; and experiments were carried out to validate the model predictions. Using independently determined membrane transport coefficients, strong agreement between the model predictions and experimental results was observed.

Session B12 DMP: Focus Session: Complex Oxide Interfaces - Titanates

314 - Mikel Holcomb, West Virginia University

11:15AM B12.00001 First-principles modeling of titanate/ruthenate superlattices[1]

, JAVIER JUNQUERA, Universidad de Cantabria — The possibility to create highly confined two-dimensional electron gases (2DEG) at oxide interfaces has generated much excitement during the last few years. The most widely studied system is the 2DEG formed at the LaO/TiO_2 polar interface between $LaAlO_3$ and $SrTiO_3$, where the polar catastrophe at the interface has been invoked as the driving force. More recently, partial or complete delta doping of the Sr or Ti cations at a single layer of a $SrTiO_3$ matrix has also been used to generate 2DEG. Following this recipe, we report first principles characterization of the structural and electronic properties of $(SrTiO_3)_5/(SrRuO_3)_1$ superlattices, where all the Ti of a given layer have been replaced by Ru. We show that the system exhibits a spin-polarized two-dimensional electron gas extremely confined to the $4d$ orbitals of Ru in the $SrRuO_3$ layer, a fact that is independent of the level of correlation included in the simulations. For hybrid functionals or LDA+U, every interface in the superlattice behaves as minority-spin half-metal ferromagnet, with a magnetic moment of $\mu = 2.0\ \mu_B/SrRuO_3$ unit. The shape of the electronic density of states, half metallicity and magnetism are explained in terms of a simplified tight-binding model, considering only the t_{2g} orbitals plus (i) the bi-dimensionality of the system, and (ii) strong electron correlations. Possible applications are discussed, from their eventual role in thermoelectric applications to the possible tuning of ferromagnetic properties of the 2DEG with the polarization of the dielectric. Work done in collaboration with P. García, M. Verissimo-Alves, D. I. Bilc, and Ph. Ghosez.

11:51AM B12.00002 Polarization controlled Ohmic to Schottky transition at a metallic oxide-doped ferroelectric interface

, XIAOHUI LIU, YONG WANG, J.D. BURTON, EVGENY TSYMBAL, Department of Physics and Astronomy, University of Nebraska - Lincoln — Recently the coexistence of ferroelectricity and conductivity was observed in electron-doped $BaTiO_3$ [1], opening an exciting avenue for novel ferroelectric device applications. A basic structure which may be used for future applications is the metal/ferroelectric hetero-junction. Using first-principles methods and taking the $SrRuO_3/BaTiO_3$ interface as a prototypical system, we investigate the effects of polarization reversal in $BaTiO_3$ on the electronic transport across this interface. Our studies show a significant change in the resistance by switching ferroelectric polarization. This arises due to the polarization driven conversion of the interface from the Ohmic to the Schottky regime, i.e. for one polarization orientation the interface exhibits a tunneling barrier, whereas the interface is metallic for the opposite polarization orientation. Our prediction represents a new path for ferroelectric devices and may lead to exciting new applications as non-volatile memories and logic.

12:03PM B12.00003 Controlling the density of electrons in the 2DEG at complex oxide interfaces[1] , CHRIS VAN DE WALLE, LARS BJAALIE, LUKE GORDON, ANDERSON JANOTTI, Materials Department, University of California, Santa Barbara — The formation of a two-dimensional electron gas (2DEG) at the interface between two insulators, $SrTiO_3$ (STO) and $LaAlO_3$ (LAO), has sparked huge interest in oxide electronics. In spite of almost a decade of research, the mechanisms that determine the density of this 2DEG have not yet been unravelled. The polar discontinuity at the STO/LAO interface can in principle sustain an electron density of $3.3x10^{14}$ cm^{-2} (0.5 electrons per unit cell). However, experimentally observed densities are more than an order of magnitude lower. Using a combination of first-principles and Schrödinger-Poisson simulations we investigate the origin of the electrons in the 2DEG at the STO/LAO interface. We analyze the asymmetric nature of the heterostructures, i.e., the inability to form a second LAO/STO interface that is a mirror image of the first, and the effects of passivation of the LAO surface. Our results apply to oxide interfaces in general, and explain why the $SrTiO_3/GdTiO_3$ interface has been found to exhibit the full density of 0.5 electrons per unit cell.

12:15PM B12.00004 Two-dimensional superconductivity induced by high-mobility carrier doping in LaTiO3/SrTiO3 hetero-structures , JOHAN BISCARAS, S. HURAND, C. PALMA, J. LESUEUR, N. BERGEAL, LPEM-UMR8213/CNRS-ESPCI ParisTech, Paris, France, D. LEBOEUF, C. PROUST, LNCMI, UPR 3228, (CNRS-INSA-UJF-UPS), Toulouse, France, A. RASTOGI, R.C. BUDHANI, Cond. Matter-Low Dimensional Syst. Lab., Dept. of Physics, IIT Kanpur, India — Transition metal oxides display a great variety of quantum electronic behaviors where correlations often play an important role. The achievement of high quality epitaxial interfaces involving such materials gives a unique opportunity to engineer artificial materials where new electronic orders take place. It has been shown recently that a two-dimensional electron gas 2DEG could form at the interface of two insulators such as LaAlO3 and SrTiO3, or LaTiO3 (a Mott insulator) and SrTiO3 [1,2]. We show that a superconducting two-dimensional electron gas is formed at the LaTiO3/SrTiO3 interface whose properties can be modulated by field effect using a metallic gate on the back of the substrate [3,4]. The gas consists of two types of carriers : a majority of low-mobility carriers always present, and a few high-mobility ones that can be injected by electrostatic doping. The calculation of the electrons spatial distribution in the confinement potential shows that the high-mobility electrons responsible for superconductivity set at the edge of the gas whose extension can be tuned by field effect [4].

12:27PM B12.00005 Incipient 2D Mott insulators in extreme high electron density, ultra-thin GdTiO3/SrTiO3/GdTiO3 quantum wells[1] , S. JAMES ALLEN, DANIEL G. OUELLETTE, POUYA MOETAKEF, TYLER CAIN, RU CHEN, LEON BALENTS, SUSANNE STEMMER, UC Santa Barbara — By reducing the number of SrO planes in a $GdTiO_3$ /$SrTiO_3$/ $GdTiO_3$ quantum well heterostructure, an electron gas with $\sim$ fixed 2D electron density can be driven close to the Mott metal insulator transition - a quantum critical point at $\sim$1 electron per unit cell. A single interface between the Mott insulator $GdTiO_3$ and band insulator $SrTiO_3$ has been shown to introduce $\sim 1/2$ electron per interface unit cell. Two interfaces produce a quantum well with $\sim 7\ 10^{14}$ cm^{-2} electrons: at the limit of a single SrO layer it may produce a 2D magnetic Mott insulator. We use temperature and frequency dependent (DC - 3eV) conductivity and temperature dependent magneto-transport to understand the relative importance of electron-electron interactions, electron-phonon interactions, and surface roughness scattering as the electron gas is compressed toward the quantum critical point. Terahertz time-domain and FTIR spectroscopies, measure the frequency dependent carrier mass and scattering rate, and the mid-IR polaron absorption as a function of quantum well thickness. At the extreme limit of a single SrO plane, we observe insulating behavior with an optical gap substantially less than that of the surrounding $GdTiO_3$, suggesting a novel 2D Mott insulator.

[1]MURI program of the Army Research Office - Grant No. W911-NF-09-1-0398

12:39PM B12.00006 Possible Mott physics in $SrTiO_3/GdTiO_3$ superlattices , RU CHEN, Department of Physics, University of California, Santa Barbara, CA-93106-9530, SUNGBIN LEE, Department of Physics, University of Toronto, Ontario, Canada, M5S 1A7, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA-93106-9530 — We perform generalized gradient approximation (GGA) + Hubbard U to study the thickness-dependent metal to insulator transition in $SrTiO_3/GdTiO_3$ superlattices. A full structural optimization procedure is applied, showing significant electronic and structural reconstruction near the interface between the band insulator $SrTiO_3$ and Mott insulator $GdTiO_3$. In addition, we find high charge density at the interface, close to half electron per interface unit cell (pseudo-cubic notation). For the insulating ultra-thin $SrTiO_3$ layer case, we are able to describe it by a low energy effective Hamiltonian. Using Hartree-Fock approximation, we find the combining effect of the hopping parameters and the correlation in the d orbitals of Ti can lead to possible Mott insulating state. Finally, magnetism is also studied and compared with the GGA+U result.

12:51PM B12.00007 Engineering new properties in $PbTiO_3$ based superlattices: compositionally broken inversion symmetry and polarization rotation[1] , MATTHEW DAWBER, Stony Brook University — In this talk I will present results on two superlattice systems which contain ultra fine layers of $PbTiO_3$ and another perovskite material. In recent years, much work has been done on the $PbTiO_3/SrTiO_3$ system, with a focus on improper ferroelectricity and the arrangement of ferroelectric domains. Here, we consider two different partner materials for $PbTiO_3$, each of which introduces markedly different behavior in the resulting superlattice. $PbTiO_3/SrRuO_3$ superlattices with ultra-thin $SrRuO_3$ layers were studied both experimentally and using density functional theory. Due to the superlattice geometry, the samples show a large anisotropy in their electrical resistivity, which can be controlled by changing the thickness of the $PbTiO_3$ layers. Therefore, along the ferroelectric direction, $SrRuO_3$ layers can act as dielectric, rather than metallic, elements. We show that, by reducing the thickness of the $PbTiO_3$ layers, an increasingly important effect of polarization asymmetry due to compositional inversion symmetry breaking occurs. The compositional inversion symmetry breaking is seen in this bi-color superlattice due to the combined variation of A and B site ions within the superlattice. We have also achieved an experimental enhancement of the piezoelectric response and dielectric tunability in artificially layered epitaxial $PbTiO_3/CaTiO_3$ superlattices through an engineered rotation of the polarization direction. As the relative layer thicknesses within the superlattice were changed from sample to sample we found evidence for polarization rotation in multiple x-ray diffraction measurements. Associated changes in functional properties were seen in electrical measurements and piezoforce microscopy. These results demonstrate a new approach to inducing polarization rotation under ambient conditions in an artificially layered thin film.

1:27PM B12.00008 Observation of the cubic Rashba effect in a $SrTiO_3$ two-dimensional electron gas , HIROYUKI NAKAMURA, Osaka University, HISASHI INOUE, SLAC National Accelerator Laboratory and Stanford University, MINU KIM, SLAC National Accelerator Laboratory and Seoul National University, CHRIS BELL, SLAC National Accelerator Laboratory, MASAYUKI HOSODA, SLAC National Accelerator Laboratory and the University of Tokyo, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HIROSHI KOHNO, Osaka University, TAKAAKI KOGA, Hokkaido University, HAROLD HWANG, SLAC National Accelerator Laboratory and Stanford University, TSUYOSHI KIMURA, Osaka University — Induced spin-orbit coupling effects at oxide interfaces, where d-orbitals form the conduction bands, are recently attracting much interest [1-4]. Here, we report magnetotransport of normally-off $SrTiO_3$ field-effect transistors with parylene gate insulator at a dilution refrigerator temperatures (50 mK - 1 K). An enlarged contribution of the weak antilocalization /weak localization (WL/WAL) effect in the magnetoconductance compared to that at 2 K [4] is used to analyze the Rashba effect in detail. It will be shown that a theoretical model with effective magnetic field configuration based on the cubic Rashba term perfectly matches the observed WL/WAL data.

1:39PM B12.00009 Ionic liquid gating of strontium titanate nanostructures , PATRICK GALLAGHER, Department of Physics, Stanford University, Stanford, CA, 94305, USA, SAM STANWYCK, Department of Applied Physics, Stanford University, Stanford, CA, 94305, USA, MENYOUNG LEE, JAMES WILLIAMS, DAVID GOLDHABER-GORDON, Department of Physics, Stanford University, Stanford, CA, 94305, USA — We present electronic transport measurements of two-dimensional electron systems (2DES) induced on strontium titanate surfaces. Using a combination of ionic liquid gates and nanopatterned metallic gates, we demonstrate the ability to isolate a nanoscale puddle of the 2DES and modulate its conductance over several orders of magnitude. Finally, we discuss the apparently gate-tunable superconducting behavior in these devices.

1:51PM B12.00010 Transport Measurements of Mesoscopic Hall Bars on Strontium Titanate , SAM STANWYCK, Department of Applied Physics, Stanford University, Stanford, CA, 94305, USA, PATRICK GALLAGHER, JAMES WILLIAMS, DAVID GOLDHABER-GORDON, Department of Physics, Stanford University, Stanford, CA, 94305, USA — We report low-temperature transport measurements of a two-dimensional electron system (2DES) at the surface of Strontium Titanate. We use electrolyte gating to create the 2DES, and then use nanopatterning techniques to define submicron constrictions with gate tunability. We observe features characteristic of superconducting transport through these small constrictions, including a critical current and critical field, but measure a nonzero resistance at zero bias. We consider possible explanations in light of these results, including large spatial inhomogeneities in the order parameter, as well as finite-size effects.

2:03PM B12.00011 Importance of oxygen vacancies for the two-dimensional metallic state at the surface of $SrTiO_3$, JUAN SHEN, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt/Main, 60438 Frankfurt, Germany — We analyze by means of density functional theory (DFT) the electronic structure of various oxygen-deficient $SrTiO_3$ surface slabs. We find a significant surface reconstruction after introducing oxygen vacancies and we show that the charges resulting from surface-localized oxygen vacancies –independently of the oxygen concentration– redistribute in the surface region and deplete rapidly within a few layers from the surface suggesting the formation of a two-dimensional electron system (2DES). We also investigate possible oxygen-vacancy clustering effects and discuss our results in the context of recent angle-resolved photoemission spectroscopy observations of a highly metallic 2DES at the (001) vacuum-cleaved surface of $SrTiO_3$.

Session B13 DMP: Focus Session: Topological Materials - Topological Superconductors and Half Heuslers 315 - Jagadeesh Moodera, Massachusetts Institute of Technology

11:15AM B13.00001 Search for Topological Superconductivity in Superconducting Doped Topological Insulators[1] , SATOSHI SASAKI, Institute of Science and Industrial Research, Osaka University — Recent discovery of topological insulators (TIs) which can be characterized by topologically protected gapless surface states stimulated the search for an even more exotic state of matter, a topological superconductor (TSC), which is also predicted to have a topologically protected gapless surface state consisting of massless Majorana fermions as its distinctive characteristic. Low-carrier-density semiconductors with a strong spin-orbit coupling and a Fermi surface that is centered around time-reversal-invariant momenta, such as superconducting doped TIs, are predicted to be prime candidates for TSCs [1]. Following this prediction, we studied the nature of superconductivity in doped TIs, $Cu_xBi_2Se_3$ and $Sn_{1-x}In_xTe$, by employing a conductance spectroscopy [2, 3]. I will present our latest results together with recent spectroscopy data from other groups, and summarize the current understanding of topological superconductivity in superconducting doped TIs. Work in collaboration with M. Kriener, Z. Ren, A. A. Taskin, K. Segawa, Y. Ando (Osaka Univ.), K. Yada, M. Sato, Y. Tanaka (Nagoya), and L. Fu (MIT).

11:51AM B13.00002 Reversibility of Superconductivity in CuxBi2Se3 via Quenching Conditions[1] , JOHN SCHNEELOCH, RUIDAN ZHONG, ZHIJUN XU, ALINA YANG, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory — We investigated the effect of various growth and annealing conditions on $Cu_{0.3}Bi_2Se_3$, a compound proposed to host topological superconductivity. For annealing temperature $T > 580^\circ$C, quenching was found necessary for superconductivity, and the superconductivity loss due to not quenching after annealing was reversible by further annealing and quenching. For $T < 580^\circ$C, annealing was detrimental, even when followed by quenching. Floating zone growth and the annealing of thin (< 1 mm) crystals were found to be detrimental to superconductivity.

12:03PM B13.00003 Crystal growth and physical property of Bi-Sb-Te-Se topological insulator materials, and Cu-Bi-Se and Sn-In-Te topological superconductors[1] , GENDA GU, ALINA YANG, J. SCHNEELOCH, R.D. ZHONG, Z.J. XU, J.M. TRANQUADA, Z.H. PAN, W.D. SI, X.Y. SHI, Q. LI, T. VALLA, Brookhaven National Laboratory — The discovery of 3D topological insulator materials and topological superconductor opens up a new research field in the condensed matter physics. We have grown a number of Bi-Sb-Te-Se topological insulator, and Cu-Bi-Se and Sn-In-Te topological superconductor single crystals. We have measured the physical properties on these single crystals. We have studied the effect of growth condition and impurity on the bulk electrical conductivity of these single crystals. We try to answer two questions for the topological insulator materials if it is possible to grow the bulk-insulating topological insulator single crystals and Which maximum resistivity of these topological insulator single crystals we can grow. For the topological superconductor, we have got the bulk superconducting single crystals with a maximum Tc=4.5K.

12:15PM B13.00004 Transport property of Cu-intercalated Bi_2Se_3 , ATSUTAKA MAEDA, TAIKI YOSHINAKA, YOSHINORI IMAI, Dept. of Basic Science, the University of Tokyo, RYUSUKE KONDO, Dept. of Physics, Okayama University — $Cu_xBi_2Se_3$($T_c \sim 3.8$ K)[1] is a promising candidate material to be a topological superconductor, and it is very important to clarify the origin of its superconductivity. However, $Cu_xBi_2Se_3$ synthesized by Hor *et al.* does not show zero resistivity below T_c [1], and some concerns still remain in the quality of samples. Recently, several groups reported the successful preparation of Cu-intercalated Bi_2Se_3 with zero resistivity by an electrochemical method [2] and the Bridgman method [3]. Here, we report transport properties of single crystals of $Cu_xBi_2Se_3$ with zero resistivity prepared by the Bridgman method. We stress that the process of the quenching from a temperature of about 1000 K into cold water is of crucial importance in the crystal growth process. The grown crystal with $x = 0.10$ shows zero resistivity at about 3.2 K. We also report the results of the intercalations of different metal elements [4].

12:27PM B13.00005 Scanning Tunneling Microscopy Measurements of Superconductivity in $Cu_xBi_2Se_3$, NIV LEVY, Center for Nanoscale Science and Technology, NIST and Maryland NanoCenter, UMD, TONG ZHANG, CNST, NIST and Maryland NanoCenter, UMD, JEONGHOON HA, CNST, NIST, Maryland NanoCenter, UMD and Dept. of Phys. and Astro. SNU, FRED SHARIFI, A. ALEC TALIN, CNST, NIST, YOUNG KUK, Dept. of Phys. and Astro. SNU, JOSEPH A. STROSCIO, CNST, NIST — The discovery of topological insulators has triggered the search for new topological states of matter. A Topological superconductor (TSC) is one such state, characterized by the existence of an unconventional superconducting gap in the bulk, and gapless Andreev bound states on the surface. Recently, Cu intercalated Bi_2Se_3 was found to be superconducting with $T_C \sim 3.8$ K, and was considered a prime TSC candidate due to its band structure and strong spin-orbit coupling. A recent point contact measurement observed zero-bias conductance peaks, claiming these as evidence of surface Andreev bound states, and angle resolved photoemission spectroscopy has revealed the preservation of the topological surface states at the Fermi level. In this work we report scanning tunneling microscopy measurements of a cleaved $Cu_{0.2}Bi_2Se_3$ crystal. The measured tunneling spectrum is fully gapped and is well described by the classical s-wave BCS theory. In addition, spatially resolved measurements of the superconducting gap under an applied magnetic field found no bound states in the vortex cores. Both of these results suggest that $Cu_{0.2}Bi_2Se_3$ is a classical s-wave superconductor contrary to previous expectations and measurements. We will discuss current work examining the Cu concentration dependence.

12:39PM B13.00006 Superconductivity in three dimensional topological compound via pressure[1] , C.Q. JIN, J. ZHU, J.L. ZHANG, S.J. ZHANG, X. LI, Q.Q. LIU, X. DAI, Z. FANG, Institute of Physics, Chinese Academy of Sciences, W.G. YANG, G.Y. SHEN, H.K. MAO, HPSynC at APS, Geophysical Laboratory, Carnegie Institution of Washington — Superconductivity in topological compounds is of great importance to the study of topological quantum phenomena. Here we report investigations of superconductivity induced via pressure in Bi_2Te_3 topological single crystals with various carrier types. We will discuss the possible relations of the superconductivity to topological scenario.

[1]We acknowledge nsf & MOST of China, DOE & nsf of US for the finacial support.

12:51PM B13.00007 Effect of Indium on the Superconducting Transition Temperature of Tin Telluride , RUIDAN ZHONG, JOHN SCHNEELOCH, XIAOYA SHI, QIANG LI, JOHN TRANQUADA, GENDA GU, Brookheaven National Laboratory — Indium-doped tin telluride is one of the most appealing topological superconductors. We have grown a series of $Sn_{1-x}In_xTe$ crystals with different indium concentrations ($0.1 \leq x \leq 1.0$). The results show indium doping improves the superconducting transition temperature significantly and is highly related to the indium concentration. The maximum Tc of indium-doped tin telluride polycrystalline is 4.5K for x=0.4. Single crystals of $Sn_{1-x}In_xTe$ were also grown by the floating zone method, and their magnetic properties were characterized.

1:03PM B13.00008 The Nature of the Superconductivity of Tl_5Te_3 , KATHRYN ARPINO, DAVID WALLACE, SEYED KOOHPAYEH, JIAJIA WEN, The Johns Hopkins University, KATHARINE PAGE, Lujan Neutron Scattering Center, Los Alamos National Laboratory, TINGYONG CHEN, Arizona State University, C.L. CHIEN, TYREL MCQUEEN, The Johns Hopkins University — The search for topologically non-trivial states of matter, such as topological insulators, has sparked significant interest in the impact of spin-orbit coupling on strongly correlated electronic behaviors, such as superconductivity. The known compound Tl_5Te_3 exhibits a superconducting transition at $T_c = 2.4$ K, and contains heavy elements, making it an ideal compound in which to look for new physics at the intersection between superconductivity and strong spin-orbit coupling. In 1973, Haemmerle et al. conjectured that two-gap superconductivity might explain previous anomalous superconducting volume fractions observed in their polycrystalline samples. We have reinvestigated the superconductivity of Tl_5Te_3 using magnetic susceptibility, heat capacity, and point contact measurements on powder and single crystal samples, and resolved these previous discrepancies. Further, we report on long-range and local structure determination of superconducting and non-superconducting Tl_5Te_3 samples, as well as the relationship between structural details and the observed superconductivity.

1:15PM B13.00009 Probing for Topological Superconductivity in In-doped SnTe , JEONGHOON HA, Center for Nanoscale Science and Technology, NIST / Maryland NanoCenter, Univ. of Maryland, N. LEVY, T. ZHANG, CNST, NIST / Maryland NanoCenter, Univ. of Maryland, H. BAEK, CNST, NIST / Dept. of Physics and Astronomy, Seoul National Univ., D. ZHANG, CNST, NIST / Maryland NanoCenter, Univ. of Maryland, F. SHARIFI, CNST, NIST, Y. KUK, Dept. of Physics and Astronomy, Seoul National Univ., S. SASAKI, Z. REN, A.A. TASKIN, K. SEGAWA, Y. ANDO, Institute of Scientific and Industrial Research, Osaka Univ., L. FU, Dept. of Physics, Massachusetts Institute of Tech., J.A. STROSCIO, CNST, NIST — Recent investigations of 3D topological insulators, which have gapless surface states protected by time reversal symmetry, have drawn attention to the search for new topological states protected by other symmetries. Theories predicted the existence of topological crystalline insulators (TCIs), which have gapless surface states protected by symmetry of the crystal lattice. In this work, we use scanning tunneling spectroscopy to investigate the superconducting properties of indium-doped tin telluride ($Sn_{1-x}In_xTe$), which is predicted to be a topological crystalline insulator. In a sample with $T_c \approx 1.6$ K, the tunneling spectra show a superconducting gap of 0.2 meV, which is continuous throughout the surface of the cleaved crystal. The superconducting gap is suppressed at a critical magnetic field of B=0.50 T and dI/dV conductance maps reveal a vortex lattice in a perpendicular applied magnetic field. Measurements will be shown as a function of In doping and discussed in relation to predictions and experiments on topological superconductivity in this material.

1:27PM B13.00010 Transport and thermodynamic properties of topological semimetal candidate RPdBi (R:rare earth)[1] , YASUYUKI NAKAJIMA, RONGWEI HU, KEVIN KIRSHENBAUM, ALEX HUGHES, PAUL SYERS, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland — The search for topologically non-trivial surface states, involving topologically protected gapless states on the boundary, is one of the central activities in the search for new quantum states of matter. Resent theoretical studies have indicated that the ternary half-Heusler system RPdBi (R:rare earth) can involve strong band inversion due to spin-orbit coupling, leading to the topologically non-trivial state. To clarify possible topological aspects of these materials, we report the characterization of single-crystal samples of RPdBi by transport and thermodynamic measurements down to very low temperatures.

1:39PM B13.00011 Transport properties of the topological semi-metal LuPtBi under pressure , FAZEL FALLAH TAFTI, Unviersity of Sherbrooke, TAKENORI FUJII, University of Tokyo, ALXANDRE JUNEAU-FECTEAU, SAMUEL RENE DE COTRET, NICOLAS DOIRON-LEYRAUD, University of Sherbrooke, ATSUSHI ASAMITSU, University of Tokyo, LOUIS TAILLEFER, University of Sherbrooke, UNIVERSITY OF SHERBROOKE TEAM, UNIVERSITY OF TOKYO TEAM — We present high-pressure magneto-transport data on single crystals of LuPtBi, a member of the ternary half-Heusler family. Recent band structure calculations show that LuPtBi is a topological semi-metal at ambient pressure due to strong spin-orbit coupling [1]. By decreasing the lattice parameter, equivalent to increasing pressure, the system should become a trivial insulator We have grown single crystals of LuPtBi and studied both the field dependence and the pressure dependence of their resistivity. The field dependence shows typical semi-metal behaviour, namely a weak temperature dependence and a large magneto-resistance. The pressure dependence shows a significant increase of resistivity and a decrease of magneto-resistance with increasing pressure. We compare our experimental results to the available theoretical work on the transport properties of topological semi-metals [2].

2:03PM B13.00013 Low temperature specific heat of YBiPt , PASCOAL PAGLIUSO, Unicamp, RYAN BAUMBACH, Los Alamos National Laboratory, PRISCILA ROSA, CRIS ADRIANO, Unicamp, JOE THOMPSON, Los Alamos National Laboratory, ZACHARY FISK, University of California - Irvine — We present the specific heat measured on single crystals of the putative topological superconductor YBiPt between 0.35 and 20 K. The electronic specific coefficient per mole of compound is 0.3 mJ/ K^2. A break in slope of C/T vs T at $T_c = 0.7$ K is seen, but no jump in C. We speculate on possible trace second phase in the crystals.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B14 GMAG DMP: Focus Session: Magnetic Nanoparticles I 316 - Dario Arena, Brookhaven National Laboratory

11:15AM B14.00001 Recent advances in magnetic nanoparticles with bulk-like properties , XAVIER BATLLE, Dept. Fundamental Physics and Institute of Nanoscience and Nanotechnology, University of Barcelona, 08028 Barcelona, Catalonia, Spain — Magnetic nanoparticles (NP) are an excellent example of nanostructured materials and exhibit fascinating properties with applications in high-density recording and biomedicine. Controlling the effects of the nanostructure and surface chemistry and magnetism at the monolayer level have become relevant issues. As the size is reduced below 100 nm, deviations from bulk behavior have been attributed to finite-size effects and changes in the magnetic ordering at the surface, thus giving rise to a significant decrease in the magnetization and increase in the magnetic anisotropy. The existence of a surface spin glass-like state due to magnetic frustration has been widely suggested in ferrimagnetic NP [1]. However, in this talk, we will show that high crystal quality magnetite $Fe_{3-x}O_4$ NP of about a few nanometers in diameter and coated with different organic surfactants [2] display bulk-like structural, magnetic and electronic properties. Magnetic measurements, transmission electron microscopy, X-ray absorption and magnetic circular dichroism and Monte Carlo simulations, evidenced that none of the usual particle-like behavior is observed in high quality NP of a few nm [3]. Consequently, the magnetic and electronic disorder phenomena typically observed in those single-phase ferrimagnetic NP should not be considered as an intrinsic effect. We also performed a real-space characterization at the sub-nanometer scale, combining scanning transmission electron microscopy, electron energy loss spectroscopy and electron magnetic chiral dichroism. For the first time, we found that the surface magnetization is as high as about 70% of that of the core [4]. The comparison to density functional theory suggested the relevance of the strong surface bond between the Fe ions and the organic surfactant. All the foregoing demonstrates the key role of both the crystal quality and surface bond on the physical properties of ferrimagnetic NP and paves the way to the fabrication of the next generation of NP with optimal magnetic properties [5]. Some bio-applications will also be discussed [6].

11:51AM B14.00002 Ligand effects on the electronic structure and magnetism of magnetite surfaces , KATARZYNA BRYMORA, FLORENT CALVAYRAC, Universite du Maine, Le Mans, France — We address the effect of functionalization on the electronic and magnetic properties of magnetite surface as an indicator of the same properties in nanoparticles too big for a direct ab-initio approach. Using well-established methods and references (namely LDA+U on magnetite surfaces) we could verify the validity of our approach, and using two typical ligands, dopamine and citrate, namely π and σ electron donors, we could predict that those ligands would induce a different change in the electronic properties of the systems, but in both cases an enhancement of magnetization.

12:03PM B14.00003 Synthesis, characterization, and fabrication of magnetic nanoparticles for low energy loss applications[1] , HONGSEOK YUN, Department of Chemistry, University of Pennsylvania, JUN CHEN, VICKY DOAN-NGUYEN, Department of Materials Science and Engineering, University of Pennsylvania, JAMES KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, CHRISTOPHER MURRAY, Department of Chemistry, Department of Materials Science and Engineering, University of Pennsylvania — It is important to increase operating frequency of power electronics for miniaturization of components. Magnetic materials are used as inductor cores to increase inductance proportional to their magnetic permeability. However, traditional magnetic materials are not used at high frequency (>100MHz) because of large hysteresis and eddy current loss. Superparamagnetic nanoparticles are good candidates to resolve these problems because they have zero hysteresis loss. In addition, eddy currents can be reduced due to their high electric resistivity originating from the organic ligands on the surface. Magnetic nanoparticles such as $NiFe_2O_4$, $Ni_{1-x}Zn_xFe_2O_4$, $MnFe_3O_4$ and $ZnFe_2O_4$ have been synthesized via high temperature thermal decomposition method and can be tuned to desired size, shape and chemical composition. To understand structural and magnetic properties of nanoparticles, the nanoparticles have been characterized by TEM, SQUID, PPMS, and Network Analyzer. UV-induced polymerization and pressing method have been implemented for film deposition. Finally, AC susceptibility of the nanoparticle film have been measured and discussed for low energy-loss applications.

12:15PM B14.00004 Size-dependent optical properties of α-Fe_2O_3 nanoparticles[1] , K.R. O'NEAL, B.S. HOLINSWORTH, P. CHEN, J.L. MUSFELDT, University of Tennessee, J.M. PATETE, S.S. WONG, State University of New York at Stony Brook, S.A. MCGILL, National High Magnetic Field Laboratory — We investigated the variable temperature optical properties of nanoscale hematite (α-Fe_2O_3) with special attention to the parity-forbidden Fe^{3+} *d-d* excitation that is activated by hybridization and symmetry-breaking phonons. An oscillator strength analysis of the rhombohedra, cubes, and rice reveals that the energy of the coupling phonon scales as $(\text{size})^{-1}$. Moreover, preliminary work in high magnetic fields shows a field-induced color change. These findings are important for more deeply understanding finite length scale effects in this iconic material and other nanoscale transition metal oxides.

[1]We thank the Department of Energy (DE-FG02-01ER45885) for support of this work.

12:27PM B14.00005 Chemical Synthesis and Physical Characterization of Hexagonal Ni Nanoparticles , JOHN KLODNICKI, BRIAN KELLY, KARL UNRUH, University of Delaware — Elemental Ni nanoparticles with a hexagonal close packed (HCP) crystal structure have been prepared by the reduction of nickel acetate in diethylene glycol (DEG) without the addition of any other reactants. No metallic Ni was formed at a reaction temperature of 195 °C. At a reaction temperature of 210 °C a two phase mixture of face centered cubic (FCC) and HCP Ni was obtained. With increasing temperature, the ratio of HCP to FCC Ni increased until at 245 °CC (i.e. the boiling temperature of DEG) the reaction product was entirely HCP. The structural and magnetic properties of the HCP Ni were characterized by scanning electron microscopy (SEM), x-ray diffraction (XRD), and vibrating sample magnetometry (VSM) measurements. The SEM measurements revealed the presence of approximately spherical particles about 500 nm in diameter, as well as a number of rod-like structures. Based on a Rietveld-type analysis of the HCP Ni, best fit lattice parameters of a=0.26473(6) and c=0.43348(10) nm were obtained. Room temperature VSM measurements revealed a small magnetic moment of about 2 emu/g.

12:39PM B14.00006 Synthesis and Characterization of CoNi and FeCo Nanowires With High Coercivity[1] , J. PING LIU, NARAYAN POUDYAL, KINJAL GANDHA, University of Texas at Arlington — Ferromagnetic nanocrystals with shape anisotropy have drawn a great attention in the past decade because of their unique magnetic properties and potential applications in magnetic recording media and high performance nanocomposite magnets. CoNi and FeCo nanocrystals with different size, shape and composition were successfully synthesized via catalytic and non-catalytic chemical solution methods. It was found that the structure and morphology of the nanocrystals can be controlled by varying synthetic parameters such as solvent amount, catalyst and surfactant concentration, and heating rate. The length of the nanowires can be adjusted by changing the catalyst concentration. It has also been observed that the growth mechanisms for FeCo and CoNi nanowires are different. Magnetic properties of the FeCo and CoNi nanocrystals including coercivity and magnetization are found to be dependent on size, shape and composition of the nanowires. By optimizing the synthesis conditions, the FeCo and CoNi nanowires with enhanced magnetization and coercivity can be obtained.

12:51PM B14.00007 Structural origin of low temperature glassy relaxation in magnetic nanoparticles , SUVRA LAHA, Wayne State University, RAJESH REGMI, Memorial Sloan-Kettering Cancer Center, GAVIN LAWES, Wayne State University — Magnetic nanoparticles often exhibit glass-like relaxation features at low temperatures. Here we discuss the effects of doping boron, cobalt, gadolinium and lanthanum on the low temperature magnetic properties of Fe_3O_4 nanoparticles. We investigated the structure of the nanoparticles using both X-ray diffraction and Raman studies, and find evidence for secondary phase formation in certain samples. We acquired Transmission Electron Microscopic images to give direct information on the morphology and microstructure of these doped nanoparticles. We measured the ac out-of-phase susceptibility ($\chi^{//}$) vs temperature (T) to parameterize the low temperature glassy magnetic relaxation. All samples show low temperature magnetic relaxation, but the amplitude of the signal increases dramatically for certain dopants. We attribute these low temperature frequency-dependent magnetic relaxation features to structural defects, which are enhanced in some of the doped Fe_3O_4 nanoparticles. These studies also confirm that the low temperature relaxation in nanoparticles arises from single particle effects and are not associated with interparticle interactions.

1:03PM B14.00008 Magnetic relaxation in dipolar magnetic nanoparticle clusters[1] , ONDREJ HOVORKA, JOE BARKER, ROY CHANTRELL, The University of York, York, UK, GARY FRIEDMAN, Drexel University, Philadelphia, USA, YORK-DREXEL COLLABORATION — Understanding the role of dipolar interactions on thermal relaxation in magnetic nanoparticle (MNP) systems is of fundamental importance in magnetic recording, for optimizing the hysteresis heating contribution in the hyperthermia cancer treatment in biomedicine, or for biological and chemical sensing, for example. In this talk, we discuss our related efforts to quantify the influence of dipolar interactions on thermal relaxation in small clusters of MNPs. Setting up the master equation and solving the associated eigenvalue problem, we identify the observable relaxation time scale spectra for various types of MNP clusters, and demonstrate qualitatively different spectral characteristics depending on the point group of symmetries of the particle arrangement within the cluster – being solely a dipolar interaction effect. Our findings provide insight into open questions related to magnetic relaxation in bulk MNP systems, and may prove to be also of practical relevance, e.g., for improving robustness of methodologies in biological and chemical sensing.

1:15PM B14.00009 Reentrant superparamagnetism induced by spin glass behavior at the surfaces of magnetic nanoparticles[1] , WEI QIN, University of Science and Technology of China, XIAOGUANG LI, Fudan University, YI XIE, ZHENYU ZHANG, University of Science and Technology of China — Superparamagnetism appears when the Neel relaxation time of magnetic nanoparticles is shorter than the measurement time. Recent experimental studies of different types of magnetic nanoparticles revealed that superparamagnetic transitions could also take place below the blocking temperatures [1-3], an intriguing phenomenon tentatively termed as quantum superparamagnetism. Here we elucidate the microscopic origin of the reentrant superparamagnetism in such systems using a phenomenological model, which emphasizes the dynamical coupling between the ferromagnetic core and the spin glass surface layer of a given nanoparticle [4]. We first obtain expressions for the thermal relaxation of the total magnetization of the particle upon finite-field and zero-field cooling, then carry out numerical simulations using physically realistic materials parameters. Our findings provide a more plausible interpretation of the observed reentrant superparamagnetism beyond the previous macroscopic quantum tunneling picture.

1:27PM B14.00010 Voltage-controlled spin transport through a pair of Buckminster fullerene molecules encapsulating cobalt atoms[1] , ALIREZA SAFFARZADEH, GEORGE KIRCZENOW, Simon Fraser University — Carbon-based nanostructures such as fullerenes, carbon nanotubes, and graphene, are promising candidates for spintronic applications because of their weak spin-orbit coupling and hyperfine interaction which lead to long spin coherence lengths. In particular, a fullerene C_{60} molecule is an interesting carbon nanostructure which can be used as a molecular bridge in magnetic tunnel junctions due to its remarkable structural stability and electronic properties which make the molecule convenient for easier spin injection in magnetic nanojunctions. Here, we show that using cobalt atoms encapsulated in a pair of Buckminster fullerene molecules sandwiched between gold electrodes, density of states spin polarizations as large as 95% are found by varying the gate and/or bias voltage, due to the spin-splitting of Co $3d$ orbitals. The current-voltage characteristics and strong (up to 100%) spin polarization of the current indicate that the device can be utilized for highly efficient spin injection into nonmagnetic conductors. These results open the way to voltage-controlled spin filters and magnetic sensors using molecular magnetic junctions.

1:39PM B14.00011 Magnetization Study of Sulfur-doped Graphitic Nano-platelets and Single Walled Carbon Nanotubes , J. ZHU, L. OLIVEIRA, R. PODILA, Department of Physics and Astronomy, Kinard Lab of Physics, Clemson University, Clemson, SC 29634-0978, S. NEELESHWAR, Y.Y. CHEN, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, J. HE, M. SKOVE, A.M. RAO, Department of Physics and Astronomy, Kinard Lab of Physics, Clemson University, Clemson, SC 29634-0978, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON UNIVERSITY COLLABORATION, INSTITUTE OF PHYSICS, ACADEMIA SINICA COLLABORATION — Recently we investigated the magnetic behavior of as-prepared and sulfur doped chemically exfoliated graphene nano-platelets (GNPs) and single walled carbon nanotubes (SWCNTs). The doping was achieved by annealing desired carbon nanostructures with 0, 1.0, 1.5 and 3 at% sulfur in an evacuated quartz tube at 1000 $^{\circ}$C for 1 day, followed by multiple rinsing in alcohol and drying in vacuum to remove excess sulfur. The isothermal M vs. H as well as the temperature-dependent M vs. T measurements were obtained using a vibrating sample magnetometer. We found that sulfur doping drastically changes the magnetic behavior of the as-prepared samples (both SWCNTs and GNPs). The results of zero-field-cooling (ZFC) and field-cooling (FC) in M vs. T measurements indicated the existence of large amount of coupled super-paramagnetic domains, along with antiferromagnetic domains. The saturation magnetization decreased in S doped GNPs, while a contrasting trend was observed in S doped SWCNTs. The role of edge states and structural defects in carbon nanostructures in the observed magnetic properties will be discussed.

1:51PM B14.00012 Enhanced Magnetic Properties in Nanoparticle-Filled CNTs , K. STOJAK, S. CHANDRA, H. KHURSHID, M.H. PHAN, H. SRIKANTH, University of South Florida, Physics — There has been much interest in magnetic polymer nanocomposites (MPNCs) recently due to potential applications for EMI shielding, tunable EM devices and flexible electronics. In past studies, using ferrite fillers, we have shown MPNCs to be magnetically tunable when passing a microwave signal through films under the influence of an external magnetic field. We extend this study to include nanoparticle-filled multi-walled carbon nanotubes (CNTs) synthesized by CVD. These high-aspect ratio magnetic nanostructures, with tunable anisotropy, are of particular interest in enhancing magnetic and microwave responses in existing MPNCs. CNTs have an average diameter and length of 300nm and 6 μm, respectively and are partially filled with $CoFe_2O_4$ and $NiFe_2O_4$ nanoparticles (NPs) ($\sim$ 7nm). When comparing NPs to NP-filled CNTs, T_B increases by $\sim$ 40K and relaxation time, τ_0, increases several orders of magnitude, indicating that enclosing NPs in CNTs enhances interparticle interactions. Structural and magnetic characterization were completed using XRD, TEM and Quantum Design PPMS, using VSM and ACMS options.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B15 GMAG DMP: Focus Session: Spin-orbit Effects in Spin-dependent Transport and Dynamics 317 - Xin Fan, University of Delaware

11:15AM B15.00001 Observation of spin Hall effective field , XIN FAN, JUN WU, YUNPENG CHEN, MATTHEW JERRY, Department of Phyiscs and Astronomy, University of Delaware, HUAIWU ZHANG, State Key Laboratory of Electronic Films and Integrated Devices, University of Electronic Science and Technology of China, JOHN XIAO, Department of Phyiscs and Astronomy, University of Delaware — Recent development in spin Hall driven spin transfer torque has attracted intensive interests[1]. Liu *et. al.* has shown that the spin transfer torque induced by the spin Hall effect in a normal metal-ferromagnetic metal bilayer can switch the magnetization of the ferromagnetic layer, which may be a potential candidate for magnetic random access memory[2]. The switching of the magnetization was primarily attributed to the Slonczewski torque[3]. We show that besides the Slonczewski torque, the spin Hall effect also produces an effective field that can also facilitate the magnetization reversal. This effective field persists even with a Cu spacer layer, and reduces quickly with the increase of the ferromagnetic layer thickness. The observation of the spin Hall effective field shall have ramification on the understanding of both spin transfer torque and spin Hall effect. 1. K. Ando *et. al.*, Electric manipulation of spin relaxation using the spin Hall effect, Physical Review Letters, 101, 036601 (2008). 2. L. Liu *et. al.*, Spin-Torque Switching with the Giant Spin Hall Effect of Tantalum. *Science* 336, 555-558 (2012). 3. J. 11:27AM B15.00002 Analysis of the spin Hall magnetoresistance in ferromagnetic insulator/normal metal hybrids[1]

, MATTHIAS ALTHAMMER, University of Alabama, SIBYLLE MEYER, MICHAEL SCHREIER, MATHIAS WEILER, STEPHAN GEPRÄGS, MATTHIAS OPEL, HANS HUEBL, RUDOLF GROSS, Walther-Meissner-Institut, TIMO KUSCHEL, CHRISTOPH KLEWE, JAN-MICHAEL SCHMALHORST, GÜNTER REISS, Universität Bielefeld, ARUNAVA GUPTA, University of Alabama, YAN-TING CHEN, Delft University of Technology, GERRIT E.W. BAUER, HIROYASU NAKAYAMA, EIJI SAITOH, Tohoku University, SEBASTIAN T.B. GOENNENWEIN, Walther-Meissner-Institut — Pure spin currents, i.e. the net flow of spin angular momentum without an accompanying charge current, represent a new paradigm for spin transport and spintronics. We have experimentally studied a new type of magnetoresistance effect, which arises from the interaction of charge and spin current flows in ferromagnetic insulator/normal metal hybrid structures. In more detail, we measured the resistance of yttrium iron garnet(YIG)/Pt, YIG/nonferromagnet/Pt, nickel ferrite/Pt, and magnetite/Pt hybrid structures as a function of the magnitude and the orientation of an external magnetic field. The resistance changes observed can be quantitatively traced back to the combined action of spin Hall and inverse spin Hall effect in the Pt metal layer, and are thus termed spin Hall magnetoresistance (SMR). We show that the SMR is qualitatively different from the conventional anisotropic magnetoresistance effect arising in magnetic metals. Furthermore, the SMR enables us to quantify the spin Hall angle in our Pt layers.

[1]Financial support by the DFG via SPP 1538 (project no. GO 944/4) and the Nanoinitiative Munich (NIM) is gratefully acknowledged.

11:39AM B15.00003 Transverse magnetoresistance and size effects of thin gold films: Experiment and theory.[1]

, RAUL C. MUNOZ, Department of Physics/University of Chile, S. OYARZUN, LPMCN/Universite Lyon-1 CNRS, R. HENRIQUEZ, Department of Physics/Universidad Santa Maria, M.A. SUAREZ, L. MORAGA, Department of Physics/University of Chile, G. KREMER, Bachillerato/Facultad de Ciencias/University of Chile — We report new experimental data regarding the transverse magnetoresistance measured with the electric field **E** oriented perpendicular to the magnetic field **B**, both fields (**E**, **B**) contained within the plane of the film (the MacDonald configuration) performed in a family of gold films of different thickness. The signal at 4 K can be univocally attributed to electron-surface scattering. Transport measurements were performed at low temperatures T ($4K \leq T \leq 50K$) under magnetic field strengths B ($1.5\ T \leq B \leq 9\ T$). The magnetoresistance signal exhibits a marked thickness dependence, and its curvature as a function of magnetic field B varies with film thickness. We also present a new theoretical description based upon a solution of Boltzmann Transport Equation [MacDonald D. C. K. and Sarginson K., 1950 *Proc. Roy. Soc. (London)* **A 203** 223], computed using the method of characteristics proposed by Chambers [Chambers R. G., 1950 *Proc. Roy. Soc. (London)* **A 202** 378]. The theoretical description of the magnetic field dependence of the magnetoresistance requires a Hall field that varies with the thickness of the film; this Hall field is tuned to reproduce the experimental data.

[1]Funding by FONDECYT 1120198 is graftefully acknowledged.

11:51AM B15.00004 Angular dependence of spin-orbit spin transfer torque[1]

, KYUNG-JIN LEE, Department of Materials Science and Engineering, Korea University — Magnetocrystalline anisotropy arises from the modification of electron states by spin-orbit coupling and is determined by integrating over all occupied electron states. On the other hand, current-induced spin transfer torques arise from the changes in torques that arise from changes in electron populations in the presence of a current. In this respect, spin transfer torques caused by spin-orbit coupling can be interpreted as current-induced corrections to the magnetic anisotropy. From this perspective, we expect a close relationship between the magnetic anisotropy and spin-orbit spin torques. We theoretically study this relationship between magnetic anisotropy and spin-orbit spin torque for a ferromagnet subject to Rashba spin-orbit coupling. For a two-dimensional free-electron model, we find that Rashba spin-orbit coupling results in perpendicular magnetic anisotropy and field-like current-induced spin transfer torques. Both quantities acquire nontrivial angular dependence as the spin-orbit coupling becomes comparable to the s-d exchange interaction. This nontrivial angular dependence can be understood from Fermi surface distortion. In the limits where either the spin-orbit coupling or the s-d exchange interaction is much greater than the other, the Fermi surface consists of two concentric circles, but when they are comparable it distorts. These free-electron calculations are in qualitative agreement with ab initio calculations for Co|Pt bilayers, suggesting that the spin-orbit coupling at the interface is non-negligible in comparison to the s-d exchange interaction there. The nontrivial angular dependence of spin-orbit spin torque may be used as an indicator of strong interfacial spin-orbit coupling, because the spin-orbit spin torque that is induced by the spin Hall effect, has a simple $\sin\theta$ dependence where θ is the angle between the magnetization and the spin injected into a ferromagnet. This work has been done in collaboration with M. D. Stiles and P. M. Haney.

12:27PM B15.00005 Spin transfer torques in magnetic bilayers with strong spin orbit coupling

, M.D. STILES, PAUL M. HANEY, Center for Nanoscale Science and Technology, NIST, Gaithersburg, USA, HYUN-WOO LEE, PCTP and Department of Physics, Pohang University of Science and Technology, Korea, KYUNG-JIN LEE, Korea University, Department of Material Science & Engineering, South Korea, AURELIEN MANCHON, King Abdullah University of Science and Technology, Saudi Arabia — Current driven magnetic dynamics in ferromagnetic thin films on top of non-magnetic films with strong spin orbit coupling show strong current-induced torques. Several theoretical models have been proposed to explain these torques. In one model, the current flowing through the non-magnetic layer gives rise to a spin Hall current, leading to a spin current incident on the interface between the two layers. This spin current causes spin transfer torques similar to those that are important in magnetic multilayers with current flowing perpendicular to the plane. Another model proposes a torque due to the spin-orbit coupling at the interface where the inversion symmetry found in the bulk materials is broken. We model the spin transport with a semiclassical Boltzmann equation approach. Both torques are present in this model and for reasonable parameter sets are largely independent of each other. We compute the dependence of the torques on the thickness of the layers and find that it is difficult to reproduce the large sensitivity to the thickness of the ferromagnetic layer as found in several experiments. This disagreement indicates that structural or electronic properties are probably changing with the thickness of the films studied in experiments.

12:39PM B15.00006 Spin transfer torque devices utilizing the spin Hall effect of tungsten

, CHI-FENG PAI, LUQIAO LIU, YUN LI, HSIN-WEI TSENG, DANIEL C. RALPH, ROBERT A. BUHRMAN, Cornell University — It is recently been shown that the spin Hall effect (SHE) in β-Ta generates a transverse spin current that is sufficient for efficiently reversing the moment of adjacent thin film nanomagnets through the spin torque (ST) mechanism. Here we report the existence of an even larger SHE in β-W thin films. Using spin torque induced ferromagnetic resonance (ST-FMR) with a β-W/CoFeB bilayer microstrip we have determined the magnitude of the spin Hall angle θ to be 0.30 ± 0.02, which is twice as large as the previously reported value for β-Ta ($\sim$0.15). From switching data obtained with 3-terminal devices consisting of a β-W channel and an adjacent CoFeB/MgO/CoFeB magnetic tunnel junction, we have independently determined $|\theta| = 0.33\pm0.06$. We will also report on the variation of the spin Hall switching efficiency with W layers of different resistivities and hence of variable (α and β) phase composition. Finally we have studied the SHE exhibited by several other 4d and 5d transition metals using the techniques mentioned above and we will report on those results.

12:51PM B15.00007 Spin-Hall and spin-pumping effect observed in W/FeCoB thin films , YUN LI, CHI-FENG PAI, HSIN-WEI TSENG, LUIS LEAO, DAN RALPH, ROBERT BUHRMAN, Cornell University, Ithaca,NY,14853 — The spin-Hall effect (SHE) and its reciprocal, the inverse spin-Hall effect (ISHE), are of great importance in spintronics since they enable, respectively, the conversion of a longitudinal charge current to a transverse spin current and the reverse process. Here we will report on a ferromagnetic resonance (FMR) study of FeCoB/W thin film bi-layer structures that incorporate different W thicknesses and hence difference phases. A very large negative spin Hall angle has been observed in the β-W samples and confirmed by spin-torque switching studies. Alternatively FMR measurements with bilayers containing α-W suggests a strong positive SHE, but this interpretation of the experiment is not consistent with spin torque switching studies utilizing α-W. Since the α-W FMR results also show an enhanced magnetic damping we tentatively attribute these results to a significantly enhanced spin pumping effect in α-W, relative to β-W. Magnetization measurements indicate that the two different types of FeCoB/W bilayers have substantially different interfacial magnetic anisotropy coefficients. We will discuss these results, together with the differing temperature dependence of the FMR signal in the two cases, which help point the way to understanding the origin of the giant SHE in β-W and the strong ISHE in α-W.

1:03PM B15.00008 Spin-orbit-induced spin-polarized surface states in one-atomic-layer Pb films on Si(111) , HYUNGJUN LEE, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — As a route to spintronics without magnetism, spin-orbit coupling (SOC) generates and manipulates the spin-polarized carriers, thereby providing key ingredients for spin field-effect transistors. Along this line, we investigated the spin-orbit induced effects in Pb monolayers on Si(111) substrates, modeled by $\sqrt{3} \times \sqrt{3}$ phase with Pb coverage of 4/3 ML, based on first-principles calculations with the inclusion of SOC. We focus on the electronic structures of surface states with characteristic Rashba-type spin splitting and spin texture as well as the charge flow pattern by calculating the current density distribution for the spin-polarized surface states. We also discuss our results on the difference from the spin splitting in the Shockley surface states on Au(111) surface. This work was supported by the NRF of Korea (Grant No. 2011-0018306), and computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2012-C2-14).

1:15PM B15.00009 ABSTRACT WITHDRAWN –

1:27PM B15.00010 Spin Hall Effect induced Anisotropic Magnetoresistance , PRISCILA GONZALEZ BARBA, King Abdullah University of Science and Technology, SEE-HUN YAN, LUC THOMAS, KWANG-SU RYU, STUART PARKIN, IBM Almaden Research Center, AURELIEN MANCHON, King Abdullah University of Science and Technology — Spin-orbit-induced anisotropic transport in magnetic materials, studied for more than a century, has recently experienced a renewed interest thanks to the formulation of anisotropic spin scattering in terms of Berry's curvature. Anisotropic magnetoresistance (AMR) is related to the scattering of the transport electrons on the orbitals of localized electrons, depending on the magnetization direction. The contributions of the interfaces on AMR has been scarcely studied. We consider a trilayer composed of one ferromagnetic layer sandwiched between two normal metals. The normal metals display spin Hall effect (SHE), whereas the ferromagnetic layer polarize the flowing current. We propose that SHE present in the top and bottom layers might contribute to the AMR. The charge and spin currents are analyzed by drift-diffusion equations including the role of inverse SHE as well as anomalous Hall effect. Longitudinal and transverse spin accumulations at the interfaces are captured through spin dependent conductance and the mixing conductance. It is shown that the presence of a spin accumulation in the normal metal close to the interface is transformed into a charge current through inverse SHE hence altering the conductivity of the normal metal. The obtained total resistivity calculation indicates its own spin accumulation profile dependance.

1:39PM B15.00011 Influence of spin-orbit interactions on the electronic structure and magnetic properties of IrMn alloys , HUA CHEN, PANTELEIMON LAPAS, FENGCHENG WU, ALLAN H. MACDONALD, University of Texas at Austin — We will present a theoretical study of the electronic and magnetic properties of non-collinear antiferromagnetic metals with strong spin-orbit interactions, focusing on the particular case of the IrMn alloy. IrMn alloys are important antiferromagnetic materials often used as the pinning layer in spin-valve structures. Their electronic structure has so far not been extensively studied; in particular the influence of spin-orbit interactions which are strong in this material has not yet been addressed. We start from ab initio calculations for ordered $IrMn_3$ crystals, and analyze the relationships between band degeneracy, non-collinearity of the Mn spins, and the large spin-orbit coupling of Ir. We will also study the spin wave spectra in the ordered $IrMn_3$, and finally comment on the influence of transport currents on magnetization structure and dynamics in antiferromagnets in general, and non-collinear systems in particular.

1:51PM B15.00012 Theory of Tunneling Anisotropic Magnetoresistance Using the Tight-Binding Green's Function Approach , VIVEK AMIN, Department of Physics and Astronomy, Texas A&M University, JAN ZEMEN, The University of Nottingham, JAN MASEK, Institute of Physics, Academy of Sciences of the Czech Republic, JAIRO SINOVA, Department of Physics and Astronomy, Texas A&M University, TOMAS JUNGWIRTH, Institute of Physics, Academy of Sciences of the Czech Republic — An increasing experimental and theoretical understanding of magnetic tunnel junctions has led to widespread application within magnetic hard drives and furthered our understanding of spin valve-like processes fundamental to Spintronics. Crucial to this understanding is the investigation of tunneling processes between single ferromagnetic layers and tunnel barriers. We present a theoretical study of the Tunneling Anisotropic Magnetoresistance (TAMR) in a Co/Pt junction with a tunnel barrier. We calculate conductance as a function of magnetization direction using the Landauer-Buttiker formula. The system Hamiltonian is obtained by means of a suitable tight-binding model fitted to ab-initio calculations, while the transmission is computed via the Green's function formalism.

2:03PM B15.00013 Inelastic process at finite temperature in 2D mutil-band systems , JACOB GAYLES, HUAWEI GAO, JAIRO SINOVA, Department of Physics and Astronomy, Texas A&M University, TX 77843 — Despite the recent progress in the understanding of the contributions to the anomalous Hall effect, however there is still a lacking in understanding the role of inelastic processes at finite temperatures and the role of strong disorder. We use numerical methods and the Kubo Formalism to explore this regime multiband systems with spin-orbit coupling. Some experiments with the use of residual conductivity have been interpreted so that extrinsic mechanisms have a strong dependence on the increase in temperature while the anomalous hall conductivity reaches a steady state value.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B16 GMAG DMP: Focus Session: Spin-Dependent Physics in Graphene 318 - Minn-Tsong Lin, National Taiwan University

11:15AM B16.00001 Magnetic Moment Formation in Graphene Detected by Scattering of Pure Spin Currents , ADRIAN SWARTZ, KATHY MCCREARY, JEN-RU CHEN, WEI HAN, University of California, Riverside, JAROSLAV FABIAN, University of Regensburg, ROLAND KAWAKAMI, University of California, Riverside — Graphene's 2D nature and high surface sensitivity have led to fascinating predictions for induced spin-based phenomena through careful control of adsorbates, including the extrinsic spin Hall effect, band gap opening, and induced magnetism. By taking advantage of atomic scale control provided by MBE, we have investigated deposition of adsorbates and their interactions with graphene. Spin transport measurements performed in-situ during systematic introduction of atomic hydrogen demonstrated that hydrogen adsorbed on graphene forms magnetic moments that couple via exchange to the injected spin current. The observed behavior is quantitatively explained utilizing a phenomenological theory for scattering of pure spin currents by localized magnetic moments. Lattice vacancies show similar behavior, indicating that the moments originate from so called pz-orbital defects. On the other hand, experiments with charge impurity scatterers such as Mg and Au, are noticeably absent of features related to magnetic moment formation. Furthermore, we observe gate dependent effective exchange fields due to the spin-spin coupling between conduction electrons and magnetic moments, which are of interest for novel phenomena and spintronic functionality but have not been seen previously in graphene.

11:27AM B16.00002 ABSTRACT WITHDRAWN –

11:39AM B16.00003 Spin Transport Measurements in Hydrogenated Graphene Devices , GAVIN KOON, JAYAKUMAR BALAKRISHNAN, BARBAROS OEZYILMAZ, Department of Physics, National University of Singapore — Graphene with all its extraordinary properties still fall short when it comes to manipulation of electron spins. Chemically modified Graphene has been explored by many to further enhance Graphene properties, tailoring it to suit desired application purposes. Here we study the effects of hydrogenation rate on graphene spin transport, spin relaxation time and length in this defected system. These findings are important for future theoretical and experimental studies on other adatoms modified Graphene.

11:51AM B16.00004 Magnetic Insulators-Induced Proximity Effects in Graphene , ALI HALLAL, HONGXIN YANG, DAMIEN TERRADE, SPINTEC, CEA/CNRS/UJF-Grenoble 1/Grenoble-INP, INAC, Fr-38054, Grenoble, France, XAVIER WAINTAL, SPSMS-INAC-CEA, 17 rue des Martyrs, Fr-38054, Grenoble France, STEPHAN ROCHE[1], Institucio Catalana de Recerca i Estudis Avanats (ICREA), 08010 Barcelona, Spain, MAIRBEK CHSHIEV, SPINTEC, CEA/CNRS/UJF-Grenoble 1/Grenoble-INP, INAC, Fr-38054, Grenoble, France — Due to its very long spin diffusion lengths up to room temperature, emergence of magnetism in graphene has attracted a lot of research interest in the field of spintronics. Several methods have been proposed to magnetize graphene, from edge magnetism, to depositing magnetic atoms or molecules, and using ferromagnetic substrate. We present first-principles calculations of spin-dependent properties in graphene induced by its interaction with ferromagnetic insulator EuO, and show that this proximity effect results in spin polarization of graphene π orbitals by up to 24% together with large exchange splitting bandgap of about 36 meV. Moreover, the position of the Dirac cone is shown to depend strongly on the graphene-EuO interlayer distance. These findings pave the way towards the possible engineering of graphene spin gating by proximity effect especially in a view of recent experiments on successful growth of Europium oxide on top of graphene.

12:03PM B16.00005 Spin pumping at Permalloy/graphene interfaces , SIMRANJEET SINGH, BRETT BARIN, Department of Physics, University of Central Florida, Orlando, Fl, AJIT KUMAR PATRA, BARBAROS ÖZYILMAZ, Department of Physics, National University of Singapore, Singapore, ENRIQUE DELBARCO, Department of Physics, University of Central Florida, Orlando, Fl — We present evidence of large spin relaxation effects in CVD graphene observed by means of ferromagnetic resonance (FMR) measurements of Permalloy/graphene (Py/Gr) bilayers. A substantial increase of the FMR linewidth in the Py/Gr bilayer, as compared to the Py layer, is interpreted in terms of an enhancement of the Gilbert damping in the ferromagnetic layer as a consequence of spin pumping at the Py/Gr interface, which is driven by the Py magnetization dynamics (i.e. precession of the magnetization induced by the microwave stimulus at resonance). The remarkable increase in the FMR linewidth compares with observations in other bilayer systems in where thick layers (thicker than the spin diffusion length) of heavy metals with strong spin-orbit interaction are employed as the non-magnetic layer. Our results indicate that spin relaxation in CVD graphene must be greatly enhanced in order to account for the losses of angular momentum by the ferromagnet. We will also present a comparative study of the Gilbert damping in Py/NM films employing highly ordered pyrolitic graphene as the non-magnetic layer, for which a more moderate broadening of the FMR linewidth is observed.

12:15PM B16.00006 Probing Spin Orbit Interaction in Single Layer Graphene via Electronic Transport[1] , SERGIO ULLOA, Ohio University and Freie Universität, Berlin, MAHMOUD ASMAR, Ohio University — An important effect on the dynamics of spins in materials is the spin orbit interaction (SOI), which may reflect or arise from intrinsic symmetries in the lattice structure, or via broken symmetries (Rashba interaction) in the system. Resonant scatterers, limiting electron mobility in graphene, are realized by impurities such as hydrogen atoms, molecules, clusters of impurities, vacancies, or metallic islands deposited on (or grown under) the surface of graphene. Resonant scatterers can also generate or enhance the Rashba SOI in graphene samples. We have developed analytical spinor solutions of the Dirac equation that include spin dependent observables, and use these to examine the role of SOI on scattering cross sections.By making use of the ratio of the total to transport cross section in the system at low energy, we predict a strong enhancement in the scattering isotropy in the presence of the intrinsic SOI. Similarly, we see fundamental changes in resonant scatterers in the presence of the Rashba SOI, which also lead to enhanced isotropy. We will discuss how these results have implications on the better characterization of impurities in graphene samples, and how typical experimental results can provide quantitative estimates of the SOI present in the system.

12:27PM B16.00007 Rashba Spin Orbit Interaction and Birefringent Electron Optics in Graphene[1] , MAHMOUD ASMAR, Ohio University, SERGIO ULLOA, Ohio University and Freie Universität, Berlin — Analogies between geometrical optics and electron trajectories have resulted in a number of interesting proposals for device applications, where material interfaces play a similar role to that of transparent interfaces in physical optics. Optical birefringence in materials arising from crystal anisotropies are manifested as different group velocities for different polarizations of light. By making use of analytical solutions of the Dirac equation, and extending the partial wave component method of scattering to include spin dependent observables, we show that an equivalent phenomenon to optical birefringence in electron optics is feasible in two dimensional graphene. The electronic birefringence arises from the intrinsic graphene structure and requires the presence of Rashba spin-orbit interaction. The different group velocities depend on the chirality of the electronic states, mimicking the light polarization dependence of the group velocities in optical birefringent materials. In circular regions containing large Rashba interaction and reversed charge density (Veselago lenses), we predict the formation of sets of double caustics and cusps, where the spacing between the two different chiral cusps is proportional to the strength of the Rashba interaction in the system.

[1]Supported by NSF MWN/CIAM and NSF PIRE.

12:39PM B16.00008 Colossal spin-orbit coupling in functionalized graphene , JAYAKUMAR BALAKRISHNAN, GAVIN KOON, BARBAROS OEZYILMAZ, Department of Physics, National University of Singapore — Graphene's low intrinsic spin orbit (SO) interaction strongly limits the realization of several functional spintronics devices. It is therefore quite desirable to develop methods to tune this SO coupling strength. Among the different approaches, the functionalization of graphene seems to be more promising from an application perspective. Recent theoretical and experimental results on functionalized graphene have shown interesting magnetic properties. Here, we will show our preliminary spin-transport results on such functionally modified graphene and discuss the various possibilities it holds for future graphene-based spintronics applications.

12:51PM B16.00009 Spin waves in graphene nanoribbon devices , FRANCISCO CULCHAC, Universidade Federal do Rio de Janeiro, ANDREA LATGÉ, Instituto de Física, Universidade Federal Fluminense, RODRIGO CAPAZ, Instituto de Física, Universidade Federal do Rio de Janeiro, ANTONIO COSTA, Instituto de Física, Universidade Federal Fluminense — We investigate spin excitations and electronic properties of graphene nanoribbon devices with zigzag edges. The magnetic region of the device is coupled to nonmagnetic metallic leads. The ground state of the magnetic region is described self-consistently within a mean-field scheme. Spin excitations are extracted from the transverse dynamic spin susceptibility. Several standing-wave modes can be identified. We study the behavior of these modes as the coupling between the magnetic region and the leads is varied. A central point found is that for a finite zigzag nanoribbon, spin excitations are damped at all finite energies. The signature of antiferromagnetic correlations is still present in the predominantly linear relationship between the standing-mode energy and the mode wave vector. The effect of an external doping is also considered and, as in the infinite case, it is found that ferromagnetic order along the ribbon's edges becomes unstable at modest doping levels. We also show the behavior of the spin excitations in the infinite zigzag nanoribbons when an electric field is applied in the transversal direction. As it is well known, this system presents a half-metallic state. A reduction of the spin-wave lifetime is found for increasing electric field intensities.

1:03PM B16.00010 Spin transport studies in encapsulated CVD graphene , AHMET AVSAR, JUN YOU TAN, YUDA HO, GAVIN KOON, BARBAROS OEZYILMAZ, Department of Physics, National University of Singapore — Spin transport studies in exfoliated graphene on SiO2/Si substrates have shown spin relaxation times that are orders of magnitude shorter than the theoretical predictions. Similar to the charge transport case, the underlying substrate is expected to be the limiting factor. The recent work Zomer, P. J. et al. [1] shows that spin transport over lengths up to 20um is possible in high mobility exfoliated graphene devices on boron nitride (BN) substrates. Here we discuss our initial attempts to repeat such spin transport experiments with CVD graphene on BN substrates. The effect of encapsulation of such devices with an extra BN layer will be also discussed. [1] Zomer, P. J.; Guimaraes, M. H. D.; Tombros, N.; van Wees, B. J. ArXiv:1209.1999, 2012

1:15PM B16.00011 Suppression of spin relaxation due to weak localization in multilayer graphene spin valves , TAKEHIRO YAMAGUCHI, IIS, Univ. of Tokyo, SATORU MASUBUCHI, IIS and INQIE, Univ. of Tokyo, KAZUYUKI IGUCHI, RAI MORIYA, IIS, Univ. of Tokyo, TOMOKI MACHIDA, IIS and INQIE, Univ. of Tokyo, and PRESTO-JST — Graphene is a promising material for spintronics devices because of its long spin diffusion length. In addition, graphene is a fascinating system where quantum interference phenomena such as weak localization and Fabry-Perot interference can be observed because of its long phase coherent length at low temperature. Therefore, graphene is an ideal system for exploring the physics of spin transport and spin relaxation under the phase coherent system. In this study, we fabricated multilayer graphene spin valve devices [1] and investigated temperature dependence of spin transport and spin relaxation properties. Spin relaxation time obtained by Hanle effect with nonlocal geometry was found to start increasing below 70 K and reach 2.5 ns at 2 K. Under the same temperature range, we also found weak localization emerged. These results suggest the correlation of spin relaxation and phase coherent transport in graphene [2]. [1] T. Yamaguchi et al., J. Magn. Magn. Mater. 324, 849 (2012), [2] T. Yamaguchi et al., submitted

1:27PM B16.00012 Long Electron Spin Lifetimes in Armchair Graphene Nanoribbons , MATTHIAS DROTH, GUIDO BURKARD, University of Konstanz, 78457 Konstanz, Germany — Armchair graphene nanoribbons (aGNR) are promising as a host material for electron spin qubits because of their potential for scalability and long coherence times [1]. The spin lifetime T_1 is limited by spin relaxation, where the Zeeman energy is absorbed by lattice vibrations [2], mediated by spin-orbit and electron-phonon coupling. We have calculated T_1 by treating all couplings analytically and find that T_1 can be in the range of seconds for several reasons: (i) Van Vleck cancellation; (ii) weak spin-orbit coupling; (iii) low phonon density; (iv) vanishing coupling to out-of-plane modes due to the electronic structure of the aGNR. Owing to the vanishing nuclear spin of ^{12}C , T_1 is a good measure for overall coherence. These results and recent advances in the controlled production of graphene nanoribbons [3] make this system interesting for classical and quantum spintronics applications.

1:39PM B16.00013 Giant magnetic anisotropy of 5d dopants in graphene and boron nitride monolayer[1] , JUN HU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697 — Searching for novel magnetic nanostructures is urgent due to the need for the miniaturization of spintronics devices. One of the main bottlenecks for this is the low blocking temperature (<10 K) in most magnetic nanoentities studied so far. In this work, we predict that extremely high blocking temperature can be achieved in graphene or boron nitride monolayer by embedding 5d transition metal (TM) atoms, based on density functional theory calculations. For example, the size of the magnetocrystalline anisotropy energy (MAE) of Re/graphene or Re/BN can be larger than 20 meV for each Re atom, sufficient for room temperature magnetic recording and spintronics applications. We provide physical insights for the further development of nanostructures with larger MAE.

[1]This work was supported by DOE-BES (Grant No: DE-FG02-05ER46237) and by NERSC for computing time.

1:51PM B16.00014 Magneto-Resistance in thin film boron carbides , ELENA ECHEVERRIA, University of Nebraska-Lincoln, GUANGFU LUO, University of Nebraska at Omaha, J. LIU, University of Nebraska-Lincoln, WAI-NING MEI, University of Nebraska at Omaha, F.L. PASQUALE, University of North Texas, J. COLON SANTANTA, P.A. DOWBEN, LE ZHANG, University of Nebraska-Lincoln, J.A. KELBER, University of North Texas — Chromium doped semiconducting boron carbide devices were fabricated based on a carborane icosahedra ($B_{10}C_2H_{12}$) precursor via plasma enhanced chemical vapor deposition, and the transition metal atoms found to dope pairwise on adjacent icosahedra site locations. Models spin-polarized electronic structure calculations of the doped semiconducting boron carbides indicate that some transition metal (such as Cr) doped semiconducting boron carbides may act as excellent spin filters when used as the dielectric barrier in a magnetic tunnel junction structure. In the case of chromium doping, there may be considerable enhancements in the magneto-resistance of the heterostructure. To this end, current to voltage curves and magneto-transport measurements were performed in various semiconducting boron carbide both in and out plane. The I-V curves as a function of external magnetic field exhibit strong magnetoresistive effects which are enhanced at liquid Nitrogen temperatures. The mechanism for these effects will be discussed in the context of theoretical calculations.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B17 DMP GMAG: Focus Session: Iridate Mott Insulators 319 - Stephen Wilson, Boston College

11:15AM B17.00001 Infrared study of the electronic structure of metallic pyrochlore iridate $Bi_2Ir_2O_7$, YUNSANG LEE, Soongsil University, S.J. MOON, Hanyang University, SCOTT C. RIGGS, M.C. SHAPIRO, I.R. FISHER, Stanford University, A.F. KEMPER, Lawrence Berkeley National Laboratory, D.N. BASOV, University of California at San Diego — We investigated the electronic properties of a single crystal of metallic pyrochlore iridate $Bi_2Ir_2O_7$ by using the infrared spectroscopy. Our optical conductivity data show the splitting of t_{2g} bands into $J_{\rm eff}$ ones due to strong spin-orbit coupling. We observed a sizable mid-infrared absorption near 0.2 eV within the $J_{\rm eff,1/2}$ bands, which indicates that this material may belong to a class of correlated system. Our findings suggest that the electronic structure of $Bi_2Ir_2O_7$ is governed by the strong spin-orbit coupling and the correlation effect, which is prerequisite for theoretically proposed non-trivial topological phases in pyrochlore iridates. We also discuss possible existence of the very far-infrared region of suppression in the optical conductivity of the compound.

11:27AM B17.00002 Electronic Structure of Spin-Orbital-Coupling-Driven Insulator Sr_2IrO_4 from Angle-Resolved Photoemission Spectroscopy , YAN LIU, XIAOWEN JIA, DAIXIANG MOU, LIN ZHAO, JUNFENG HE, GUODONG LIU, SHAOLONG HE, YINGYING PENG, CHAOYU CHEN, XIAOLI DONG, JUN ZHANG, National Lab for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics CAS, Beijing 100190, China, ZUYAN XU, CHUANGTIAN CHEN, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, Beijing 100190, China, GANG CAO, Center for Advanced Materials and Department of Physics and Astronomy, University of Kentucky, X.J. ZHOU, National Lab for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics CAS, Beijing 100190, China — Sr_2IrO_4, as a Mott Insulator, is an ideal system to study spin orbital coupling interaction in transition metal oxides. We report a comprehensive investigation on electronic structure of Sr_2IrO_4 by high resolution angle-resolved photoemission spectroscopy (ARPES). We measured the Fermi surface and band structures at different photon energies, under different photon polarizations. New features have been revealed that were not observed in previous studies. Moreover, the measurement under different polarizations helps identify different orbital characteristics of bands. The comparison between our experimental observations and theoretical calculation proves the important role of spin-orbital coupling interaction in determining its electron structure. The rich information on the electron structure of Sr_2IrO_4 will provide key insights in understanding the mechanism of various electron interactions in determining its insulator ground state.

11:39AM B17.00003 Crystal field splitting and correlation effect on the electronic structure of A_2IrO_3 , HLYNUR GRETARSSON, J.P. CLANCY, University of Toronto, X. LIU, J.P. HILL, E. BOZIN, Brookhaven National Laboratory, Y. SINGH, Indian Institute of Science Education and Research Mohali, S. MANNI, P. GEGENWART, Georg-August-Universitat Gottingen, J. KIM, A.H. SAID, D. CASA, T. GOG, M.H. UPTON, Argonne National Laboratory, H.S. KIM, J. YU, Seoul National University, V.M. KATUKURI, L. HOZOI, J.V.D. BRINK, IFW Dresden, Y.J. KIM, University of Toronto — The electronic structure of the honeycomb lattice iridates Na_2IrO_3 and Li_2IrO_3 has been investigated using resonant inelastic x-ray scattering (RIXS). Crystal-field split d–d excitations are resolved in the high-resolution RIXS spectra. In particular, the splitting due to non-cubic crystal fields, derived from the splitting of $j_{\rm eff}$=3/2 states, is much smaller than the typical spin-orbit energy scale in iridates, validating the applicability of $j_{\rm eff}$ physics in A_2IrO_3. We also find excitonic enhancement of the particle-hole excitation gap around 0.4 eV, indicating that the nearest-neighbor Coulomb interaction could be large. These findings suggest that both Na_2IrO_3 and Li_2IrO_3 can be described as spin-orbit Mott insulators, similar to the square lattice iridate Sr_2IrO_4.

11:51AM B17.00004 Quasimolecular electronic structure of Na_2IrO_3 , IGOR MAZIN, Naval Research, HARALD JESCHKE, FOYEVTSEVA KATERYNA, ROSER VALENTI, University of Frankfurt, DANIEL KHOMSKII, University of Cologne — Spin-orbit (SO) coupling can lead to many nontrivial effects such as Rashba effect, topological insulators, or topologically protected states in systems described the Heisenberg-Kitaev model, recently proposed for Na_2IrO_3. This proposal is based on the fact the SO coupling for iridium is very strong, and cannot be quenched by the small trigonal crystal field. We show, however, that Na_2IrO_3 represents a highly unusual case, in which the electronic structure is dominated by the formation of quasi-molecular composite orbitals (QMOs). The QMOs consist of six atomic orbitals on an Ir hexagon, and the orbital moment of each QMO is quenched, so that spin-orbit effects only affect the inter-QMO interaction. The concept of such composite orbitals in solids is completely new, and invokes very different physics compared to the models considered previously. For instance, one has to account for Hubbard correlations among the QMOs, and not individual atomic orbitals. Both the insulating behavior and the experimentally observed zigzag antiferromagnetism in Na_2IrO_3 naturally follow from the QMO model.

12:03PM B17.00005 Magnetic properties of triangular lattice Ca_4IrO_6 and $Ca_{2.5}Sr_{1.5}IrO_6$[1] , K.H. BUTROUNA, L. LI, T.F. QI, O.B. KORNETA, J. TERZIC, E. AKBARI, S. PARKIN, Center for Advanced Materials, University of Kentucky, S.J. YUAN, Department of Physics, Shanghai University, G. CAO, Center for Advanced Materials, University of Kentucky — We report a structural, thermodynamic, and transport study of single-crystal Ca_4IrO_6 and $Ca_{2.5}Sr_{1.5}IrO_6$. The isostructural Ca_4IrO_6 and $Ca_{2.5}Sr_{1.5}IrO_6$ feature a triangular lattice of spin chains running along the *c* axis. The underlying properties of the two systems are characterized by a partial antiferromagnetic order occuring at 12 K and 9 K for Ca_4IrO_6 and $Ca_{2.5}Sr_{1.5}IrO_6$, respectively, a small entropy removal associated with the phase transition, and a sizable low-temperature specific heat linearly proportional to temperature. The detailed results will be discussed along with comparisons drawn with other related systems such as $Ca_5Ir_3O_{12}$.

12:15PM B17.00006 Electronic and magnetic phase evolution in $Sr_3(Ir_{1-x}Ru_x)_2O_7$, CHETAN DHITAL, TOM HOGAN, KEVIN LUKAS, STEVEN DISSLER, CYRIL OPEIL, STEPHEN WILSON, Boston College — A great deal of recent focus has been given to understanding how the interplay of strong spin orbit coupling effects and onsite coulomb repulsion change the conventional energy hierarchy in correlated 5d electron iridium oxides. Contrary to conventional band theory, perovskite iridate compounds Sr2IrO4 and Sr3Ir2O7 have long been known to be insulators; however many of their fundamental electronic properties and the interactions responsible for generating their antiferromagnetic insulating ground states remain under investigation. Here, we report results from our transport and magnetization study of electronic and magnetic phase of Sr3Ir1-xRuxO7. The evolution of the phase behavior as Sr3Ir2O7 is tuned from an AF insulator to a paramagnetic metal and the potential for a first order metal to insulator transition will be discussed.

12:27PM B17.00007 Magnetic properties of Mn-doped Sr2IrO4[1] , M.D. LUMSDEN, S. CALDER, Oak Ridge National Laboratory, G.-X. CAO, University of Tennessee and Oak Ridge National Laboratory, J.W. KIM, Argonne National Laboratory, Z. GAI, B.C. SALES, Oak Ridge National Laboratory, D. MANDRUS, University of Tennessee and Oak Ridge National Laboratory, A.D. CHRISTIANSON, Oak Ridge National Laboratory — In 5d electron transition metal oxides, interplay between spin-orbit coupling and electronic interactions can lead to novel properties. One example is the Mott state in Sr_2IrO_4 which is believed to be associated with the formation of a J_{eff}=1/2 band due to large spin-orbit splitting of the t_{2g} band. We use bulk measurements and resonant magnetic x-ray scattering to explore the effects of substituting Mn for Ir in single crystals of $Sr_2Ir_{0.9}Mn_{0.1}O_4$. These measurements indicate that 10% Mn doping is sufficient to suppress the magnetic ordering temperature from 240 K to 155 K. Resonant magnetic x-ray scattering measurements indicate a change in the long-range magnetic order when compared to that of undoped Sr_2IrO_4. Despite the large change in transition temperature and the altered magnetic structure, we observe a difference in the resonant enhancement between the L_2 and L_3 edges which is very similar to that seen in the pure material. This suggests that the magnetic structure of Sr_2IrO_4 can be altered by small perturbations whereas the J_{eff}=1/2 state is robust.

12:39PM B17.00008 Weak magnetic transitions in pyrochlore $Bi_2Ir_2O_7$

PETER BAKER, FRANCIS PRATT, ISIS Facility, STFC Rutherford Appleton Laboratory, Didcot, OX11 0QX, UK, JOHANNES MOELLER, BIL HAYES, STEPHEN BLUNDELL, Oxford University Department of Physics, Oxford, OX1 3PU, UK, TOM LANCASTER, University of Durham, Centre for Materials Physics, Durham, DH1 3LE, UK, TONGFEI QI, GANG CAO, Department of Physics and Center for Advanced Materials, University of Kentucky, Lexington, KY40506 — The pyrochlore iridate $Bi_2Ir_2O_7$ is analogous to the rare earth pyrochlores RIr_2O_7 (R = Y and Pr-Lu) but has no rare earth moments or f electrons to interact with the Ir subsystem. This makes it an ideal system in which to study the Ir magnetism in isolation. Bulk measurements showed that it is metallic down to 2K and no indication of magnetic ordering was found down to 50mK. The magnetic field dependence of the low-temperature specific heat shows large changes in both the linear and cubic contributions and the large Wilson ratio of 53.5 suggests proximity to a quantum critical point [1]. Our muon spin relaxation measurements find a bulk magnetic transition at $1.84(3)$K and the form of the data suggests that the low-temperature state represents ordering of exceptionally small magnetic moments with persistent weak dynamics. The relaxation rate increases further below $0.23(4)$K, coincident with a growth in the specific heat, suggesting another magnetic transition. The magnetic field experienced by muons is ~ 0.7T at low-temperature, around two orders of magnitude smaller than that in other pyrochlore iridates, corresponding to moments $\sim 0.01\ \mu_B$/Ir.

12:51PM B17.00009 Theory on Magnetic Excitation Spectra in Pyrochlore Iridates[1]

ERIC KIN-HO LEE, University of Toronto, SUBHRO BHATTACHARJEE, University of Toronto, McMaster University, YONG BAEK KIM, University of Toronto, Korea Institute for Advanced Study — Metal-insulator transitions in pyrochlore iridates ($A_2Ir_2O_7$) are believed to occur due to subtle interplay of spin-orbit coupling, geometric frustration, and electron interactions. In particular, the nature of magnetic ordering of iridium ions in the insulating phase is crucial for understanding of several exotic phases recently proposed for these materials. We study the spectrum of magnetic excitations in the intermediate-coupling regime for the so-called all-in/all-out magnetic state in pyrochlore iridates with non-magnetic A-site ions (A=Eu,Y), which is found to be preferred in previous theoretical studies. We find that the effect of charge fluctuations on the spin-waves in this regime leads to strong departure from the lowest-order spin-wave calculations based on models obtained in strong-coupling calculations. We discuss the characteristic features of the magnetic excitation spectrum that can lead to conclusive identification of the magnetic order in future resonant inelastic x-ray (or neutron) scattering experiments. Knowledge of the nature of magnetic order and its low-energy features may also provide useful information on the accompanying metal-insulator transition.

1:03PM B17.00010 Spin-Orbit Coupling in Mott Insulators: Unusual Interactions and Possible Exotic Phases

GEORGE JACKELI, Max Planck Institute for Solid State Research, Stuttgart, Germany — Over the last few years, there has been an upsurge of interest in materials in which exotic states may emerge as the result of relativistic spin-orbit interactions. We will discuss insulating iridium oxides from this perspective. We show that the strong spin-orbit coupling, through the entanglement of spin and orbital spaces, leads to a variety of interesting Hamiltonians ranging from the Heisenberg model to the Kitaev or quantum compass models, for different lattice geometries [1]. Based on these effective Hamiltonians, we present a comprehensive theoretical study [1-3] of the rich phase behavior and dynamics observed in layered iridium oxides such as tetragonal Sr_2IrO_4 and $Sr_3Ir_2O_7$ and hexagonal A_2IrO_3 (A=Na, Li). We suggest that the hexagonal iridates might be close to the Kitaev spin-liquid state. We also discuss the layered tetragonal vanadate Sr_2VO_4 and argue that magnetically-hidden octupolar order, driven by spin-orbit coupling, is realized in this compound [4].

1:39PM B17.00011 ARPES Studies of Low-energy electronic structure of the strong spin-orbit semimetal $SrIrO_3$

YUEFENG NIE, PHILIP D.C. KING, HAOFEI WEI, MASAKI UCHIDA, JOHN HARTER, ERIC MONKMAN, DANIEL SHAI, DARRELL SCHLOM, KYLE SHEN, Cornell University — The similar energy scales of spin-orbit coupling and electron-electron correlation strength lead to exotic $J_{eff} = 1/2$ Mott insulating ground states for layered Ruddlesden-Popper 5d iridates, $Sr_{n+1}Ir_nO_{3n+1}$. A metal-insulator transition occurs upon increasing dimensionality from the two-dimensional layered Sr_2IrO_4 to the three-dimensional perovskite $SrIrO_3$. However, little is known about the electronic structure and nature of the metallic states in $SrIrO_3$. We synthesized epitaxial $SrIrO_3$ films on (001) LSAT substrates by molecular beam epitaxy and investigated their electronic structure using angle-resolved photoemission spectroscopy. We find an exotic semi-metallic state comprised of massive hole-like bands, whose extrema are pinned very close to the chemical potential, and rapidly dispersive electron bands which dominate the transport. Intriguingly, the bandwidths of $SrIrO_3$ are smaller than in its Mott insulating counterpart Sr_2IrO_4, indicating that metal-insulator transitions in Ruddlesden-Popper iridates are not simply driven by band narrowing resulting from reduced dimensionality.

1:51PM B17.00012 High-magnetic-field-tuned insulating state in single-crystal $BaIrO_3$[1]

O.B. KORNETA, T.F. QI, L. LI, K. BUTROUNA, G. CAO, Department of Physics and Astronomy and Center for Advanced Materials, University of Kentucky, E.S. CHOI, National High Magnetic Field Lab, XIANGANG WAN, Department of Physics, Nanjing University, China — $BaIrO_3$ is a novel magnetic insulator associated with the spin-orbit interaction. It magnetically orders at $T_C = 182$ K, with an extremely small saturation moment $M_S < 0.03\ \mu_B/Ir$. Application of high magnetic field up to 35 Tesla results in an exotic behavior characterized by: (1) a drastic rise in electrical resistivity by 250% at low temperatures and (2) highly anisotropic magnetoresistivity with unusually strong hysteretic behavior. Our first principle calculations suggest a band structure near Fermi surface extremely sensitive to slight changes in lattice parameters, which captures underlying physical properties observed experimentally. The giant positive magnetoresistivity along with the extremely small saturation moment signals a delicate interplay between the structural and the electronic degrees of freedom in this compound. The electrical transport and magnetic properties in high magnetic field will be presented and discussed.

2:03PM B17.00013 Magnetism in double-perovskite Sr_2GdIrO_6 and Sr_2YIrO_6[1]

J. TERZIC, T.F. QI, L. LI, O.B. KORNETA, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, S. PARKIN, Center for Advanced Materials, Department of Chemistry, University of Kentucky, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky — Sr_2GdIrO_6 and Sr_2YIrO_6 with $Ir^{5+}(5d^4)$ ions are magnetic insulators with a double-perovskite structure derived from the perovskite $SrIrO_3$, which is a paramagnetic metal. We report results of our study of structural and physical properties of single-crystal Sr_2GdIrO_6 and Sr_2YIrO_6. This study reveals that while Sr_2YIrO_6 exhibits no long-range order above 1.7 K, Sr_2GdIrO_6 displays an anisotropic and antiferromagnetic state at low temperatures that is clearly manifested in the magnetization and specific heat. The results will be presented and discussed along with comparison drawn with other related iridates driven by the strong spin-orbit interaction.

Session B18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Spin Valleytronics and Spin Orbit 320 - Aubrey Hanbicki, Naval Research Laboratory

11:15AM B18.00001 Valley polarization and intervalley scattering in monolayer MoS_2 , G. KIOSEOGLOU, University of Crete, A.T. HANBICKI, M. CURRIE, A.L. FRIEDMAN, D. GUNLYCKE, B.T. JONKER, Naval Research Lab — Single layer MoS_2 is a prime candidate material for implementing valleytronics because minima in the bandstructure at inequivalent K points of the Brillouin zone can be independently populated, thus making the valley index a potential state variable for information processing. Light of a particular helicity populates only one of the two K-valleys (either K or K') resulting in a strong emission at around 1.9 eV associated with a direct transition. We use energy and helicity dependent optical pumping to analyze the coupling of the valley and spin indices to the depolarization of emitted light. The circular polarization of the photoluminescence is very high for photo-excitation near the bandgap, and has a power-law decrease as the photo-excitation energy increases. We identify phonon-assisted intervalley scattering as the primary spin relaxation mechanism and present a model of depolarization that explains the wide variation in values for the optical polarization reported in the literature. Our results elucidate the basic processes that control the unique properties of this material and should help to realize future valleytronic applications. This work was supported by core programs at NRL and the NRL Nanoscience Institute.

11:27AM B18.00002 Theoretical analysis of optical excitation and luminescence in MoS_2 monolayers[1] , HANAN DERY, Department of Electrical and Computer Engineering, Department of Physics and Astronomy, University of Rochester, Rochester, New York, 14627, YANG SONG, Department of Physics and Astronomy, University of Rochester, Rochester, New York, 14627 — We analyze the absorption and circularly polarized luminescence spectra of MoS_2 monolayers. We show that indirect optical transitions can fully explain the observed decrease in circular polarization degree when increasing the lattice temperature or the exciting photon energy. This spin-conserving optical process is assisted by electron-phonon or electron-impurity interactions giving rise to intervalley transitions to intermediate virtual states. Spin-flip mechanisms, on the other hand, are shown to be insufficient in explaining the experimental results due to their relatively long timescales compared with the radiative timescales in monolayer dichalcogenides (tens of ps).

[1]This work is supported by d NSF Contract No. DMR-1124601 (NEB 2020) and NSF Contract ECCS-1231570.

11:39AM B18.00003 Longitudinal and spin/valley Hall optical conductivity in single layer MoS_2 , ZHOU LI, JULES CARBOTTE, McMaster University — A monolayer of MoS_2 has a non-centrosymmetric crystal structure, with spin polarized bands. It is a two valley semiconductor with direct gap falling in the visible range of the electromagnetic spectrum. Its optical properties are of particular interest in relation to valleytronic and possible device applications. Circular polarized light associated with each of the two valleys separately is considered and results are filtered according to spin polarization. Temperature can greatly change the spin mixture seen in the frequency window where they are not closely in balance.

11:51AM B18.00004 Optical and Electrical Control of Valley Pseudospin in Atomically-Thin Semiconductors , XIAODONG XU, Department of Physics, University of Washington, Seattle WA 98195 — Electronic valleys are energy extrema of Bloch bands in momentum space. In analogy to electrons with spin degrees of freedom, valley indexes can be considered as pseudospins for new modes of electronic and photonic device operation. In this talk, I will discuss the experimental progress on the investigation of these pseudospins using atomically-thin semiconductors, which are either single or bilayer group VI transition metal dichalcogenides. I will show that these new 2D semiconductors not only behave as remarkable excitonic systems, but also provide an ideal system for optical and electrical control of valley degrees of freedom.

12:27PM B18.00005 Theoretical design of magnetic two-dimensional transition metal dichalcogenide semiconductors[1] , WENGUANG ZHU, University of Science and Technology of China, DI XIAO, Carnegie Mellon University — We explore the possibility of making single-layer dichalcogenide semiconductors magnetic by doping transition metal ions using density functional calculations. Optimal conditions of doping are suggested based on the study of the energetics and kinetics of magnetic ions in the host materials. The magnetic ordering and magnetic coupling mechanism between the magnetic dopants will also be discussed in this talk. This work may provide a new twist to form truly two-dimensional magnetic semiconductors for spintronic applications.

[1]Supported by NSF of China, USDOE-BES, and USNSF.

12:39PM B18.00006 Group theory analysis of the intrinsic momentum and spin relaxation in monolayer dichalcogenides[1] , YANG SONG, Department of Physics and Astronomy, University of Rochester, Rochester, New York, 14627, HANAN DERY, Department of Electrical and Computer Engineering, Department of Physics and Astronomy, University of Rochester, Rochester, New York, 14627 — Using group theory, we study the intrinsic momentum and spin relaxation of electrons and holes due to scattering with phonons in monolayer dichalcogenides. Double group symmetry representations of electron and hole states at high symmetry points (K, K', and Γ points as well as the T axis) are identified with the help of results from absorption and photoluminescence experiments. We link the leading contributions to intravalley and intervalley scattering with symmetries of the nine phonon dispersion branches. Scattering matrix elements due to short-range interaction and the corresponding Elliott-Yafet spin-flip mechanism are expressed analytically, leading to explicit wavevector-dependence and scattering integrals. Long-range interaction are similarly analyzed. Due to the absence of inversion symmetry, valley-spin coupling is revealed to be a general feature in the spin-flip scattering. Using these results we estimate the temperature-dependent relaxation times. Intervalley scattering between valleys not connected by time-reversal is shown to be compound dependent. The K to T transition (K to Γ transition) in the conduction (valence) band is relevant in heavier (lighter) compounds such as WSe_2 (MoS_2).

[1]This work is supported by d NSF Contract No. DMR-1124601 (NEB 2020) and NSF Contract ECCS-1231570.

12:51PM B18.00007 Spin-dependent phonon-assisted optical transition in Si and Ge under strain[1]

, PENGKE LI, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York, 14627, DHARA TRIVEDI, Department of Physics and Astronomy, University of Rochester, Rochester, New York, 14627, HANAN DERY, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York, 14627 — In indirect bandgap semiconductors like Si and Ge, the transfer of angular momentum between free carriers and photons is intricate since they involve both radiation-matter and electron-phonon interactions. Moreover, the multi-valley conduction band of Si and Ge leads to dependence on light propagation. By breaking the degeneracies of conduction valleys and of valence bands, strain could be used as an experimental tool to regulate and validate the relation between the measured circular polarization degree of photons and the spin polarization of charge carriers. Using symmetry arguments, we present a theoretical study of the spin-dependent selection rules for various phonon-assisted optical transitions. We show how these selection rules are changed under different configurations of strain. These selection rules are verified by rigorous numerical calculation of the spin-dependent luminescence spectra in strained Si and Ge, as well as in relaxed SiGe alloys. Lastly, we also provide results of the inverse process, namely optical orientation.

1:03PM B18.00008 Spin communications under optimized external electric field in strained group IV semiconductors[1]

, LAN QING, HANAN DERY, Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627 — We investigate factors affecting an on-chip communication paradigm that is based on modulating spin polarization of a constant current in silicon or germanium wires. Strain that quenches certain intervalley scattering can prolong the spin lifetime considerably. Necessary external electric field can accelerate the transport by increasing drift velocity, yet it also enhances the spin relaxation by heating the electrons. We predict non-monotonic behaviors of the final spin signals versus the external electric fields. Simple approximate expressions are provided for the spin lifetimes of drifting electrons in strained silicon and germanium, which enable us to choose electric fields that maximize the signals in spin transport. Even at room temperature, we can expect no significant loss of the spin signal after transport across millimeter scale. Our theoretical results are supported by recent experimental breakthroughs.

[1]This work is supported by NRI-NSF Contract No. DMR-1124601 (NEB 2020) and NSF Contract No. ECCS-1231570.

1:15PM B18.00009 Enhanced intervalley splitting and reduced spin relaxation in strained thin silicon films[1]

, DMITRI OSINTSEV, VIKTOR SVERDLOV, SIEGFRIED SELBERHERR, Institute for Microelectronics, TU Wien — We investigate the influence of strain and spin-orbit interaction on the valley splitting, subband structure, subband wave functions, and spin relaxation matrix elements due to surface roughness scattering in thin silicon films. A $\mathbf{k}\cdot\mathbf{p}$ approach suitable to describe the electron subband structure with spin [1] is generalized to include strain. The 4×4 Hamiltonian is diagonalized with respect to the spin degree by a unitary transformation. The wave functions and eigenenergies are found analytically, when the thin film is approximated by an infinite square well potential. In relaxed films the unprimed subbands are degenerate. This degeneracy produces a large mixing between the spin-up and spin-down states, resulting in spin hot spots characterized by strong spin relaxation. These hot spots are contrasted with those appearing in the bulk system [1] due to the degeneracy of the opposite valleys along certain directions close to the X-point at the edge of the Brillouin zone. Shear strain efficiently lifts the degeneracy between the unprimed subbands. This removes the origin of the spin hot spots in a confined silicon system, which substantially improves the spin lifetime in silicon films. 1.P.Li and H.Dery, *Phys.Rev.Lett.* **107**, 107203 (2011).

1:27PM B18.00010 Unified theory of spin-dynamics in a two dimensional electron gase with arbitrary spin-orbit coping strength at finite temperature[1]

, XIN LIU, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802-6300, SINOVA JAIRO, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA — We study the spin dynamics in the presence of impurity and electron-electron (e-e) scattering in a III-V semiconductor quantum well with arbitrary spin-orbit coupling (SOC) strength and symmetry at finite temperature. In the regime where the strength of the Rashba and linear Dresselhaus SOC match, known as the SU(2) symmetry point, experiments have observed the spin-helix mode with a large spin-lifetime whose unexplained nonmonotonic temperature dependence peaks at around 75 K. As a key test of our theory, we are able to naturally explain quantitatively this nonmonotonic dependence and show that it arises as a competition between the Dyakonov-Perel mechanism, suppressed at the SU(2) point, and the Elliott-Yafet mechanism. In the strong SOC regime, we show that our theory directly reproduces the previous known analytical result at the SU(2) symmetry point in the ballistic regime.

[1]We acknowledge the support from DMR-1105512, ONR-N000141110780, NHARP, and NSF-MRSEC DMR-0820414.

1:39PM B18.00011 A critical phase induced by interplay of spin-orbit coupling and Coulomb interaction

, EUN-GOOK MOON, CENKE XU, University of California, Santa Barbara, YONG BAEK KIM, University of Toronto, LEON BALENTS, Kavli Institute of Theoretical Physics — We study long range Coulomb interaction effect on the Luttinger Hamiltonian in three spatial dimensions, which describes strong spin orbit coupling intrinsically. The Hamiltonian has energy spectrum of inverted band gap semiconductors as in well-known HgTe; only one quadratic band touching point exists at the gamma point in Brillouin zone protected by the cubic and time reversal symmetries. Using controlled renormalization group techniques, we find that long-range Coulomb interaction converts the quadratic band touching state into a non-Fermi liquid (NFL) state, in some ways analogous to the Luttinger liquid state in one dimension. Consequently, all physical quantities become scale invariant and show deviations from non-interacting electrons' properties. Temperature and field dependence of various thermodynamic functions are obtained. Moreover, our ground state can be viewed as a parent state of topological insulators, magnetic metals, and Weyl semi-metals by breaking either cubic symmetry or time-reversal symmetry. The strong Coulomb interaction changes phase boundaries qualitatively and phase diagrams with the Coulomb interaction are provided. Applications to iridium-oxides materials are also discussed.

1:51PM B18.00012 3D and 4D Topological Insulators based SU(2) Landau Levels

, YI LI, Department of Physics, University of California, San Diego, SHOU-CHENG ZHANG, Department of Physics, Stanford University, CONGJUN WU, Department of Physics, University of California, San Diego — Current studies of 3D topological insulators (TIs) based on the Bloch-wave band inversion have made great success in lattices. Independent of current routine, we propose a novel and simple mechanism achieving exactly flat topological spectra for electrons in the continuum at 3D and 4D without magnetic fields. By introducing spin-orbit couplings, helical Dirac modes or chiral Weyl modes with opposite helicities are spatially separated along an extra spatial dimension and robust at boundaries as protected by the time-reversal symmetry. Moreover, based on elegant analytic wavefunctions of high dimensional Landau levels, we construct the Laughlin type wavefunction at the fractional filling in 4d. Further, parallel to the 2D QHE, whose quantized Hall response demonstrates spatially separated (1+1)D chiral anomaly, the 4D SU(2) Landau levels explicitly show the quantized non-linear electromagnetic response, which exhibits spatially separated (3+1)D chiral anomaly with the same quantization in the unit of fundamental physical constants.

2:03PM B18.00013 Spin polarization in the Hubbard model with Rashba spin-orbit coupling on a ladder , JOSE RIERA, Universidad Nacional de Rosario y CONICET, Argentina — The competition between on-site Coulomb repulsion and Rashba spin-orbit (RSO) coupling is studied on two-leg ladders by numerical techniques. Using DMRG it is found that the contribution to the current due to the RSO coupling for a fixed value of the Hubbard repulsion U reaches a maximum at intermediate values of the RSO coupling-to-hopping ratio and eventually becomes negative. This point of maximum current is correlated with the maximum value of the spin polarization between the two legs of the ladder. The most important result is that for a fixed value of the RSO coupling, the spin polarization increases with U and seems to saturate as $U \to \infty$. These behaviors are studied at various fillings in the metallic regime. Further support for these conclusions is provided by the study of persistent currents in Hubbard-Rashba models on ladder rings. The implications of this enhancement of the spin Hall effect with electron correlations for spintronic devices is discussed.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B19 DCMP: Metal Insulator transitions in Vanadates: exp/theory 321 - Mumtaz Qazilbash, College of William and Mary

11:15AM B19.00001 Nanoscale Thermal Mapping of VO_2 , ADAM PIVONKA, MAGDALENA HUEFNER, CHANGHYUN KO, ALEX FRENZEL, KEVIN O'CONNOR, SHRIRAM RAMANATHAN, Harvard University, ERIC HUDSON, The Pennsylvania State University, JENNIFER HOFFMAN, Harvard University — We present a method for nanoscale thermal imaging of insulating thin films. We image the local temperature of the metal-insulator transition in a VO_2 film, and investigate the role of Joule heating in two-terminal geometry. By sweeping the voltage applied to a conducting atomic force microscope tip in contact mode, we locally trigger and detect the transition to the metallic phase. By fitting the Poole-Frenkel conduction regime immediately preceding the transition, we extract the local temperature. Finally, we find grains displaying two electronic transitions, consistent with a locally stable intermediate insulating phase.

We acknowledge financial support from Harvard's Nanoscale Science and Engineering Center, funded by NSF grant PHY 01-17795 and the Sloan Fellowship. Adam Pivonka acknowledges the support of the New York Community Trust–George Merck Fund. Magdalena Huefner acknowledges the support of the Deutsche Forschungsgemeinschaft (HU 1960/11).

11:27AM B19.00002 Strain-dependent Metal-Insulator Tansition in VO_2 single-crystalline thin films , NAGA PHANI AETUKURI, Stanford University/IBM Almaden Research Center, ALEXANDER GRAY, SLAC National Accelerator Laboratory, MATTEO COSSALE, MARC DROUARD, LI GAO, IBM Almaden Research Center, HERMANN DURR, SLAC National Accelerator Laboratory, MAHESH SAMANT, STUART PARKIN, IBM Almaden Research Center — Vanadium dioxide (VO_2 has a near room temperature metal insulator transition ($T_{MIT} \sim$ 340 K) accompanied by a structural transition making the origin of this transition controversial. In this work, we have continuously changed T_{MIT} by as much as 60 K in VO_2 (001) single crystalline thin films by using RuO_2 buffer layers. We observe a decrease in the T_{MIT} as a function of decreasing c-axis length in the rutile phase which is unexpected from a one-dimensional Peierls model. By performing complementary bulk-sensitive spectroscopic measurements, namely, x-ray absorption spectroscopy (XAS) and x-ray photoelectron spectroscopy (XPS), we identify changes in orbital occupation and electron-electron correlations as a function of strain in the metallic state that explain the observed T_{MIT} dependence on strain.

11:39AM B19.00003 Broadband Infrared Spectroscopy of Vanadium Dioxide Films Under the Influence of Strain[1] , T.J. HUFFMAN, PENG XU, A.J. HOLLINGSHAD, N.E. PENTHORN, D.J. BROOKER, M.M. QAZILBASH, LEI WANG, R.A. LUKASZEW, Department of Physics, College of William and Mary, R.D. PIKE, Department of Chemistry, College of William and Mary, B.-J. KIM, H.-T. KIM, Center of Metal-Insulator Transition, ETRI — Vanadium dioxide (VO_2) undergoes a phase transition between an insulating monoclinic phase and a conducting rutile phase. Even in this simple, stoichiometric material, a complete explanation of the phase transition has proved elusive. This transition, like phase transitions in other correlated electron systems, involves interacting electronic, lattice, and orbital degrees of freedom. This leads to physical properties that are particularly sensitive to small changes in external parameters such as strain. VO_2 films grown on different substrates are subject to differing strain effects that often lead to a shift in the transition temperature. Broadband infrared (IR) and optical spectroscopy allows us to examine the electronic structure and dynamics as well as IR-active, zone-center phonons of strained films grown on sapphire and quartz. Comparing and contrasting the IR and optical properties of these films, and those of bulk crystals, will provide insight into the influence of strain on the electronic and lattice degrees of freedom.

11:51AM B19.00004 In-situ studies on the Martensitic-type transition in VO_2 thin films , VISWANATH BALAKRISHNAN, SHRIRAM RAMANATHAN, School of Engineering and Applied Sciences, Harvard University — We present in-situ kinetic studies across metal-insulator transition in epitaxial and polycrystalline VO_2 thin films through electrical resistance and stress measurements along with TEM investigations. Variable temperature wafer curvature experiments enable the probing of in situ stress relaxation kinetics associated with the structural component of the metal insulator transition. Primarily, no time or drive rate dependence is observed in the stress relaxations providing insight into the athermal nature of phase transition kinetics. However, proximate to the phase transition boundary, minor fraction of isothermal component that show time dependence in both stress relaxation and electrical measurement is captured. In situ electron diffraction and micro structural observations across the metal insulator transition provide evidence for martensitic type transition in polycrystalline VO_2 thin films. The studied aspects of time independent, Martensitic type, athermal transition kinetics along with negligible fraction of isothermal kinetics have significance in understanding the dynamics of structural phase transitions that accompany electronic property changes.

12:03PM B19.00005 T_c anisotropy and phase separation in strained Vanadium Dioxide films , MENGKUN LIU, MARTIN WAGNER, Department of Physics, The University of California at San Diego, La Jolla, California 92093, USA, ELSA ABREU, Department of Physics, Boston University, Boston, Massachusetts 02215, USA, SALINPORN KITTIWATANAKUL, Department of Materials Science and Engineering, University of Virginia, Charlottesville, Virginia 22904, USA, ALEXANDER MCLEOD, MICHAEL GOLDFLAM, ZHE FEI, SIYUAN DAI, MICHAEL FOGLER, Department of Physics, The University of California at San Diego, La Jolla, California 92093, USA, JIWEI LU, Department of Materials Science and Engineering, University of Virginia, Charlottesville, Virginia 22904, USA, STUART WOLF, Department of Materials Science and Engineering & Department of Physics, University of Virginia, Charlottesville, Virginia 22904, USA, RICHARD AVERITT, Department of Physics, Boston University, Boston, Massachusetts 02215, USA, D.N. BASOV, Department of Physics, The University of California at San Diego, La Jolla, California 92093, USA — We report Infrared near field study on strain induced transition temperature (T_c) anisotropy in vanadium dioxide (VO_2) films via direct visualization of a spontaneous structural and electronic phase separation. The films are epitaxially grown on $[110]_R$ or $[100]_R$ TiO_2 substrates and exhibit large uniaxial strain. By mapping the film topography with AFM and electronic percolation with Infrared scattering scanning near-field optical microscopy, a temperature dependent electron-lattice correlation can be clearly observed. Our work sheds a new light onto the nature of the Tc anomaly in metal-insulator transition and leads to the possibility of controlling the material's properties through strain induced phase separation.

12:15PM B19.00006 Hydrogen doping and the metal-insulator transition in vanadium dioxide

, TALIP SERKAN KASIRGA, CHUNMING HUANG, JAE H. PARK, JIM M. COY, ZAIYAO FEI, AARON M. JONES, XIAODONG XU, DAVID H. COBDEN, University of Washington Department of Physics — Vanadium dioxide has a first-order metal-insulator transition (MIT) at 67 °C. It has recently been shown [1] that hydrogen doping of VO_2 by spillover from a metal catalyst in hydrogen gas gradually reduces the gap in the insulating phase to zero, and eventually eliminates the MIT. The dependence on hydrogen concentration enables optical and electrical detection of the local hydrogen density. We exploit this to study the diffusion of hydrogen and its dependence on temperature, direction, strain, and phase in single-domain nanobeams and platelets of VO_2. For example, we find that diffusion is faster along the rutile c-axis, and can be significant even at the transition temperature. We also study the effects of hydrogen doping on the phase diagram, on the low temperature conductivity, and on the continuous-wave and ultrafast optical response.

12:27PM B19.00007 Comparative studies of electrically driven metal insulator transition in VO_2 single crystal and thin film

, HONGLYOUL JU, Dept. of Phys., Yonsei Univ., Seoul, Republic of Korea, BONGJIN MUN, Dept. of Applied Physics, Hanyang University, Ansan, Republic of Korea, JOONSEOK YOON, Dept. of Phys., Yonsei Univ., Seoul, Republic of Korea, SUNG-KWAN MO, ALS, LBNL, Berkeley, USA, KAI CHEN, ALS, LBNL, Berkeley, USA; CAMP-Nano State Key Laboratory for Mechanical Behavior of Materials,Xi'an Jiaotong University, Xi'an,China, NOBUMICHI TAMURA, CATHERINE DEJOIE, MARTIN KUNZ, ZHI LIU, ALS, LBNL, Berkeley, USA, YVETTE LEE, KYUNGSUN MOON, Dept. of Phys., Yonsei Univ., Seoul, Republic of Korea, CHANGWOO PARK, Division of pplied Chemistry and Biotechnology, Hanbat National University, Daejon and Advanced Nano Products, Chungwon, Republic of Korea — Electrically driven metal-insulator transition (MIT) characteristics of VO_2 single domain crystal and thin-film were investigated by temperature and external bias voltage dependent electrical transport, optical microscopy, and synchrotron-based polychromatic x-ray micro-diffraction measurements. Our results suggest that electrically driven metallic state of VO_2 is similar to that of temperature driven metallic state. However, after the electrically driven MIT, VO_2 single crystal exhibits metallic and insulating colors on the surface of the crystals simultaneously. In addition, the origin of electrically driven MIT of crystals seems different from that of electrically driven MIT films. In this talk, we will present comparative studies of electrically driven MIT of VO_2 single crystal and thin-film, and discuss the origins of electrically driven MIT and its implications.

12:39PM B19.00008 VO_2 and V_2O_3: different pathways for the same phase transition?[1]

, E. ABREU, J. ZHANG, Physics Dpt, BU, Boston MA, S. WANG, Dpt of Physics and Center for Advanced Nanoscience, UCSD; Materials Science and Eng Pgm, UCSD, La Jolla CA, K. GENG, L. CAO, Physics Dpt, BU, Boston MA, S. KITTIWATANAKUL, J. LU, Dpt of Materials Science and Eng, UVa, Charlottesville VA, M. LIU, Dpt of Physics, UCSD, La Jolla CA, J.G. RAMIREZ, Dpt of Physics and Center for Advanced Nanoscience, UCSD, La Jolla CA, S.A. WOLF, Dpt of Materials Science and Engineering, UVa, Charlottesville VA, I.K. SCHULLER, Dpt of Physics and Center for Advanced Nanoscience, UCSD; Materials Science and Eng Pgm, UCSD, La Jolla CA, R.D. AVERITT, Physics Dpt, BU, Boston MA — Decades of investigation have led to a better understanding of the properties of vanadates but a great deal remains to be explored in these scientifically fascinating and technologically relevant systems. VO_2 and V_2O_3 are canonical examples of these transition metal oxides, strongly influenced by both electronic correlations and structural effects. In both materials the MIT is known to occur following a variation in temperature, the application of a dc field, optical pumping and more recently the application of transient THz pulses. The question that naturally arises is whether and how the dynamics of the MIT depend on the nature of the stimulus that induced it. We will present time-resolved optical and THz investigations, including high THz field results, of thin films of V_2O_3 and VO_2.

[1]This work is supported by the Air Force Office of Scientific Research No. FA9550-12-1-0381, DOE DE-FG02-09ER46643 and Portugal's FCT SFRH/BD/47847/2008.

12:51PM B19.00009 The Effect of Doping on the Metal-Semiconductor Transition in VO_2

, SALINPORN KITTIWATANAKUL, STUART WOLF, Department of Physics, University of Virginia, JIWEI LU, Department of Materials Science and Engineering, University of Virginia — Vanadium dioxide (VO_2) is a well-known correlated material that exhibits a metal-semiconductor transition at 340K, with several orders of magnitude change in the resistivity. In this study, we report the effect of Mn-doping and Al-doping, with different doping recipes; the films were deposited by Reactive Biased Target Ion Beam Deposition, and their single phase was confirmed by X-ray diffractometry. The different doping recipes had a very dramatic impact on the crystallinity of the vanadium dioxide films. It was found that using a lower frequency for the pulsed dc target bias was desirable for the improvement of the film quality. Both Al and Mn doping can enhance the transition; while the Al doped VO_2 also raises the transition temperature.

1:03PM B19.00010 Benchmark study of the application of density functional theory to correlated t_{2g}^1 vanadates

, DANILO PUGGIONI, JAMES RONDINELLI, Drexel University — $SrVO_3$ and $CaVO_3$ are strongly correlated perovskite-structured metals belonging to the class of transition-metal oxides with a $3d^1$ electronic configuration. Both cubic $SrVO_3$ and orthorhombically distorted $CaVO_3$ are classified as Pauli paramagnets, yet their magnetic states at low temperature remain controversial. Here, we present and discuss the results of systematic density functional theory (DFT) calculations on the atomic and magnetic structures of both $SrVO_3$ and $CaVO_3$ to shed light on this issue. We use standard and "beyond-DFT" exchange-correlation functionals to evaluate the stable magnetic states. We conclude by discussing both the accuracy of these methods for reproducing the atomic structures of the t_{2g}^1 vanadates and their implications on artificially structured oxide superlattices.

1:15PM B19.00011 Ab initio study of metal-insulator transition in VO2[1]

, HUIHUO ZHENG, LUCAS K. WAGNER, Department of Physics, University of Illinois at Urbana-Champaign — The structure distortion accompanied metal-insulator transition (MIT) of vanadium dioxide (VO_2) at 340K has been a matter of ongoing controversy for near four decades. It is still unclear whether the nature of this transition is due to a Peierls instability, a Mott-Hubbard transition, or other physics. Most density functional theory based methods fail to describe the nature of the electronic state in this system, further complicating theoretical description of VO_2. We will report on progress in applying the first principles diffusion quantum Monte Carlo method to the electronic structure of VO_2 in the metallic and insulator phases. By examining the energetic properties, one particle reduced density matrix, as well as other static correlations in the two phases of the system, we will comment on which of the two common descriptions is a closer representation of the physical reality of VO_2.

[1]This work was supported by the Strategic Research Initiatives project at Illinois(HZ) and NSF DMR 12-06242 (LKW).

1:27PM B19.00012 Phonon Softenings and the Mott-spin-Peierls Transition in VO_2

, SOORAN KIM, KYOO KIM, CHANG-JONG KANG, B.I. MIN, POSTECH — To explore the driving mechanisms of the metal-insulator transition (MIT) and the structural transition in VO_2, we have investigated phonon dispersions of rutile VO_2 (R-VO_2) in the DFT and the DFT+U (U: Coulomb correlation) band calculations. We have found that the phonon softening instabilities occur in both cases, but the softened phonon mode only in the DFT+U describes properly both the MIT and the structural transition from R-VO_2 to monoclinic VO_2 (M_1-VO_2). The present *ab-initio* phonon dispersion calculations clearly demonstrate that the Coulomb correlation effect plays an essential role of assisting the Peierls transition in R-VO_2 and producing the spin-Peierls ground state in M_1-VO_2.

1:39PM B19.00013 Examining the density functional theory description of VO_2 above and below the metal-insulator transition[1] , RICARDO GRAU-CRESPO, THOMAS A. MELLAN, Department of Chemistry, University College London, UK, HAO WANG, UDO SCHWINGENSCHLÖGL, KAUST, PSE Division, Saudi Arabia — Vanadium oxide (VO_2) exhibits a metal-insulator transition at 341 K, which is accompanied by a change from a tetragonal to a mononoclinic structure. We examine the electronic and magnetic properties of VO_2 below and above the transition point, as calculated from density functional theory (DFT) and some extensions, including hybrid DFT / Hartree-Fock functionals and Hubbard-corrected functionals. We show that the groundstate solutions obtained with either the GGA approximation or the screened hybrid functional HSE (25% of Hartree-Fock exchange) are at odds with experimental observations for both phases. We then discuss the effect of varying amounts of Hartree-Fock exchange and values of the Hubbard parameter U on the solutions. Although the agreement of some of the calculated properties with experiment can be tuned in this way, we conclude that no single setting can describe the properties of both VO_2 phases simultaneously.

1:51PM B19.00014 Spatial complexity due to strong correlations in vanadium dioxide , SHUO LIU, BENJAMIN PHILLABAUM, ERICA CARLSON, Purdue University, KARIN DAHMEN, University of Illinois at Urbana-Champaign, MUMTAZ QAZILBASH, College of William and Mary, DMITRI BASOV, University of California, San Diego, VIDHYADHIRAJA SUDHINDRA, JNCASR — Near-field scanning infrared microscopy on the Mott metal-insulator system vanadium dioxide (VO_2) has revealed complex nanoscale pattern formation in the form of insulating and metallic puddles near the insulator-to-metal transition [1]. We use and extend recently developed cluster techniques [2] in order to understand the fundamental physics driving this multiscale pattern formation. We map the observed metallic and insulating clusters to Ising variables by a rigorous choice of threshold amplitude, and quantify the statistics of the sizes and shapes of the geometric clusters. These in turn yield critical exponents including the cluster size distribution exponent τ, and the fractal dimensions associated with the cluster formation. These quantitative measures show power-law behavior over multiple decades, revealing a delicate interplay between interactions and disorder in the material. The cluster techniques employed here can be readily applied to 2D image data in the context of other materials and measurement techniques.

2:03PM B19.00015 Structural and vibrational properties of VO2 from DFT and DFT+U calculations[1] , ERIC J. WALTER, HENRY KRAKAUER, TYLER J. HUFFMAN, PENG XU, M. M. QAZILBASH, College of William and Mary — Vanadium dioxide (VO_2) undergoes a metal-insulator transition (MIT) at 340 K from a metallic, high-temperature rutile phase to a insulating, low-temperature monoclinic phase. In thin films, the extremely fast switching times ($\simeq$ 100 femtoseconds) of the MIT have led to many suggested device applications. Understanding the MIT driving mechanism and the long-debated importance of electronic correlation is important to these developments. We have computed the relaxed geometry and phonon frequencies using DFT and DFT+U for both phases of VO_2. The dependence of vibrational mode frequencies and oscillator strengths on the Hubbard U parameter and their sensitivity to the Born effective charges in the insulating monoclinic phase will be reported. The calculated frequencies for $U = 5$ eV are in good agreement with recent experimental infrared micro-spectroscopy measurements on single crystal platelets of VO_2 [2]. Our results indicate that strong electron-electron correlation must be included to describe the vibrational properties.

Session B20 DMP: Focus Session: Mesoscopics - Transport 322 - Yvan Bruynseraede, Catholic University-Leuven, Belgium

11:15AM B20.00001 From Quanta to the Continuum: Opportunities for Mesoscale Science , JOHN SARRAO, Los Alamos National Laboratory — Mesoscale science embraces the regime where atomic granularity and quantization of energy yield to continuous matter and energy, collective behavior reaches its full potential, defects, fluctuations and statistical variation emerge, interacting degrees of freedom create new phenomena, and homogeneous behavior gives way to heterogeneous structure and dynamics. Mesoscale architectures form a hierarchy extending from atoms and molecules through polymers, supramolecular assemblies, periodic lattices, multilayers, nanocrystal arrays and multiphase materials. Mesoscale science builds on the foundation of nanoscale knowledge and tools that the community has developed over the last decade and continues to develop. Mesoscale phenomena offer a new scientific opportunity: designing architectures and interactions among nanoscale units to create new macroscopic behavior and functionality. Examples of mesoscale successes, challenges and opportunities will be described. A more complete discussion of mesoscale science can be found in the BESAC report, *From Quanta to the Continuum: Opportunities for Mesoscale Science*, http://science.energy.gov/bes/news-and-resources/reports/basic-research-needs/ Innovative community input on opportunities for mesoscale science can be found on the *Mesoscopic Materials and Chemistry* website, http://www.meso2012.com/

11:51AM B20.00002 Magnetoresistance Jumps in Mesoscopic Hybrid Devices[1] , ALI C. BASARAN, CARLOS MONTON, JUAN PEREIRO, IVAN K. SCHULLER, University of California - San Diego — We have studied the electrical transport of superconducting stripes (Nb and V) with periodically altered local magnetization. The local magnetization is controlled by the ferromagnetic states of Ni rings placed on top of the stripes. We observe a series of large resistance jumps as a function of external magnetic field (Ha). The jumps occur at temperature and current density dependent Ha values which indicate that they are probably not related to vortex pinning. Resistance jumps along with observed multiple steps in the current-voltage characteristics could be attributed to weak links induced by magnetic stray field or proximity effects originated by Ni rings in the superconducting area. The exact origin of these jumps is still under investigation.

12:03PM B20.00003 Electron transport in confined oxide nanowires[1] , GUANGLEI CHENG, MICHELLE TOMCZYK, SHICHENG LU, MENGCHEN HUANG, JOSH VEAZEY, PATRICK IRVIN, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Sciences and Engineering, University of Wisconsin-Madison, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — The invention of conductive AFM lithography at the $LaAlO_3/SrTiO_3$ interface enables the creation of clean interconnected oxide nanowires and artificially engineered tunnel barriers. Here we create an oxide nanowire that is confined by two tunnel barriers using this technique. Two terminal and four terminal transport studies reveal transitions among Cooper pair tunneling, Coulomb blockade and Fabry-Perot inteference that can be tuned by side gate voltages and external magnetic field. Our results indicate the presence of long-range coherence in $LaAlO_3/SrTiO_3$ nanowires.

12:15PM B20.00004 Electric transport in Individual GaAs nanowires , ZHUTING SUN, ANDREI KOGAN, University of Cincinnati, TIM BURGESS, CHENUPATI JAGADISH, Australian National University — We report electrical transport measurements on individual GaAs nanowires approximately 50 nm in diameter contacted via lithographically patterned Al/Ti metal films. The nonlinear current-voltage characteristics show a strongly hysteretic behavior sensitive to the device temperature and the biasing history. In hysteresis-free regimes, we compare the data to a model based on two metal-semiconductor barriers in series with the wire, and find a good overall agreement. We also discuss the effects of surface treatments on the metal-wire interface resistance. The work is supported by NSF grant DMR-1206784 and DMR-0804199 and University of Cincinnati.

12:27PM B20.00005 Coherent electron transport in InAs nanowires , MARION J. L. SOURRIBES, IVAN ISAKOV, MARINA PANFILOVA, London Centre for Nanotechnology, University College London, DANIELE ERCOLANI, FRANCESCO GIAZOTTO, LUCIA SORBA, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, PAUL A. WARBURTON, London Centre for Nanotechnology, University College London — Indium arsenide nanowires are of special interest since they exhibit high mobility, strong spin-orbit coupling and form ohmic contacts with metals which make them good candidates for the observation of Majorana fermions in semiconductor/superconductor hybrid systems. InAs nanowires have already been used as Josephson elements in superconducting devices. Here we report our low-temperature experiments on InAs nanowires grown by two methods: (i) gold-catalyzed chemical beam epitaxy on InAs (111) substrates; (ii) catalyst-free molecular beam epitaxy on Si (111) substrates. Contacts to the nanowires are defined by e-beam lithography. Before metallization of the contacts, the nanowire surface is deoxidized by an in situ sputter-cleaning process leading to a specific contact resistance of $9.8 \times 10^{-9}\,\Omega.\mathrm{cm}^2$. These highly transparent contacts allowed the observation of proximity-induced superconductivity in InAs nanowires connected with Nb contacts. The critical current was tuned by changing the gate voltage. Both magnetic-field-dependent and gate-voltage-dependent measurements of universal conductance fluctuations were performed to extract information on the electron phase coherence.

12:39PM B20.00006 End and Side Contacts to NiSi nanowires[1] , ABDEL F. ISAKOVIC, A. BELKADI, Khalifa University - KUSTAR — NiSi nanowires were nanofabricated with end and side contacts. These contacts are designed to minimize spreading resistance and are tested to check whether they can aid in decreasing the energy cost of current injection and current ejection in nanotransport. It is demonstrated that the end contacts have lower power in $1/f$ noise spectrum. Transport data (current-voltage, differential resistance) also show quantitative differences from "standard" bottom or top contacts to SiNi nanowires, indicating that the presence of edge- and end-states at the termination points of the nanowires gives rise to different transport conditions. Time-dependent correlation coefficient from noise spectra is determined and it is different for different types of contacts. Structural study of nanowires contacted in this manner is also presented.

[1]This work is supported through SRC-ATIC grant 2011-KJ-2190

12:51PM B20.00007 Strain manipulated direct-indirect band gap transition in GaAs nanowires , XIHONG PENG, ANDREW COPPLE, NATHANIEL RALSTON, Arizona State University — One dimensional nanostructures of group III-V semiconductors have drawn broad research interests in recent years due to their potential applications in nano-electronics. In particular, GaAs has been considered as a promising channel material for the high speed NMOS beyond Si based technology. In this project, electronic structures of GaAs nanowires at both wurtzite and zinc blende phases were studied using first-principles Density Functional Theory (DFT) calculations. It was found that the band gap of GaAs nanowires experience a direct-to-indirect transition when the diameter of the nanowires is smaller than a specific value [1]. For those thin GaAs nanowires with an indirect band gap, it was found that the gap can be tuned to be direct if a moderate external strain is applied. We found many types of strains, such as tensile and compressive uniaxial strain, radial strain, strain along a specific orientation in the cross-section of the nanowires, can trigger the indirect-to-direct gap transition. The critical strains for the gap-transition are determined by the energy crossover of two states in conduction bands.

1:03PM B20.00008 Local transport measurement at mesoscopic lengthscales on epitaxial graphene using scanning tunneling potentiometry , WEIGANG WANG, KO MUNAKATA, Stanford University, MICHAEL ROZLER, Rush University, MALCOLM R. BEASLEY, Stanford University — We report direct measurement of the local transport potential at mesoscopic lengthscales in epitaxial graphene by scanning tunneling potentiometry. The measurements were made possible by using slender, sharp tips manufactured by focused ion beam that avoid the previous problem of tip jumping. The sample was measured at 17K, well below the onset of weak localization; hence locally the transport was mesoscopic. Besides local Landauer residual resistivity dipoles associated with topographical features of our sample, we observed peaks and dips in the local transport potential for which there is as yet no explanation. Work supported by AFOSR MURI Contract # FA9550-09-1-0583-P00006

1:15PM B20.00009 ABSTRACT HAS BEEN MOVED TO V1.00314 —

1:27PM B20.00010 Probing spin-charge relation by magnetoconductance in one-dimensional polymer nanofibers , YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University — Polymer nanofibers are one dimensional (1-D) organic hydrocarbon systems containing conducting polymers where the non-linear local excitations such as solitons, polarons and bipolarons formed by the electron-phonon interaction were predicted. Magnetoconductance (MC) can simultaneously probe both the spin and charge of these mobile species and identify the effects of electron-electron interactions on these nonlinear excitations. Here we report our observations of a qualitatively different MC in polyacetylene (PA) and in polyaniline (PANI) and polythiophene (PT) nanofibers. In PA the MC is essentially zero, but it is present in PANI and PT. The universal scaling behavior and the zero (finite) MC in PA (PANI and PT) nanofibers provide evidence of Coulomb interactions between spinless charged solitons (interacting polarons which carry both spin and charge).

1:39PM B20.00011 On the Lifetimes of Nonaxisymmetirc Metallic Nanowires , LAN GONG, New York University, JEROME BUERKI, California State University Sacramento, CHARLES STAFFORD, University of Arizona, DANIEL STEIN, New York University — We present a theoretical approach for understanding the stability of simple metallic nanowires, in particular monovalent metals such as the alkalis and noble metals. Their cross sections are of order one nanometer so that small perturbations from external (usually thermal) noise can cause large geometrical deformations. The nanowire lifetime is defined as the time required for making a transition into a state with different cross-sectional geometry. This can be a simple overall change in radius, or a quadrupolar deformation, or both. We develop a stochastic field theoretical model to describe this noise-induced transition process, in which the initial and final states correspond to locally stable states on a potential surface derived numerically from a nearly free electron model. The numerical "string method" is implemented to determine the optimal transition path governing the lifetime. Using these results, we tabulate the lifetimes of sodium and gold nanowires of several different initial geometries.

1:51PM B20.00012 Making quantum devices with electrical properties that are robust to thermal cycling using AlGaAs/GaAs HIGFET structures , ADAM MICOLICH, ANDREW SEE, OLEH KLOCHAN, ADAM BURKE, ALEX HAMILTON, School of Physics, The University of New South Wales, Sydney NSW 2052, Australia, IAN PILGRIM, BILLY SCANNELL, RICK MONTGOMERY, RICHARD TAYLOR, Department of Physics, University of Oregon, Eugene OR 97403, MARTIN AAGESEN, POUL LINDELOF, Nanoscience Center, Niels Bohr Institute, Copenhagen, Denmark, IAN FARRER, DAVID RITCHIE, Cavendish Laboratory, Cambridge, U.K. — The transport properties of quantum devices on modulation-doped AlGaAs/GaAs heterostructures change after thermal cycling above ∼130 K due to charge redistribution in the modulation doping layer. This is particularly evident in a quantum dot's magnetoconductance fluctuations (MCF) which provide a sensitive fingerprint of electron trajectories through the dot. We show that the MCF become reproducible with high-fidelity after thermal cycling to 300 K in quantum dots made using AlGaAs/GaAs heterostructures without modulation doping. This is achieved by populating the dot electrostatically using a Heterostructure Insulated Gate Field Effect Transistor (HIGFET) architecture. Our result demonstrates ionized impurity scattering has a measurable effect on transport in quantum dots, even in the ballistic transport regime. It highlights the potential for HIGFET-based architectures to provide devices with significantly reduced small-angle scattering at equivalent transport mobility, and more thermally robust electrical properties. More broadly, we suggest a quantum dot's MCF may be a useful tool for studying the temporal/thermal stability of disorder in other semiconductor materials.

2:03PM B20.00013 Scattering phase of quantum dots: Emergence of universal behavior[1] , PHILIPPE JACQUOD, Physics Department, University of Arizona, RODOLFO JALABERT, Institut de Physique et Chimie des Materiaux de Strasbourg, RAFAEL MOLINA, Instituto de Estructura de la Materia, CSIC, Serrano, DIETMAR WEINMANN, Institut de Physique et Chimie des Materiaux de Strasbourg — We investigate scattering through chaotic ballistic quantum dots in the Coulomb-blockade regime. Focusing on the scattering phase, we show that long universal sequences emerge in the short wavelength limit of many electrons on the dot, where phase lapses of π systematically occur in between two consecutive resonances. We further argue that such universal sequences become shorter and shorter as the wavelength becomes larger/the number of electrons on the dot is reduced. Our results are corroborated by numerics and are in qualitative and quantitative agreement with experimental results. We finally present numerical data on models of interacting electrons to show that strong correlations do not alter our conclusions.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B21 DMP: Focus Session: Hexagonal Ferrites and Manganites 323 - Nicole Benedek, University of Texas at Austin

11:15AM B21.00001 Multiferroic vortices , SANG-WOOK CHEONG, SEUNG CHUL CHAE, XUEYUN WANG, FEI-TING HUANG, YOICHI HORIBE, Department of Physics and Astronomy, Rutgers University — Hexagonal $REMnO_3$ (RE=Ho, Er, Tm, Yb, Lu) is an improper ferroelectric where the size mismatch between RE layers and Mn-O layers induces a simultaneous ferroelectric-trimerization structural phase transition [1]. The six types of ferroelectric-trimerization domains merge one point, and form a vortex or antivortices, depending on vorticity. A zoo of vortices and antivortices form into a topologically-nontrivial network, and intriguing collective magnetism develops at the domain walls of the vortex-antivortex network. In addition, we found that bound states of vortices and antivortices can also develop. We will discuss the formation of the vortex-antivortex network and the vortex-antivortex bound states in terms of the interaction between two neighboring domain walls and that between a vortex and an antivortex.

11:27AM B21.00002 Unfolding Vortices to Topological stripes in a multiferroic , XUEYUN WANG, Department of Physics and Astronomy, Rutgers University, MYUNG-GEUN HAN, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, YOICHI HORIBE, Department of Physics and Astronomy, Rutgers University, TOSHIHIRO AOKI, YIMEI ZHU, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University — Hexagonal $REMnO_3$ (RE=Ho, Er, Tm, Yb, Lu) is an improper ferroelectric where the size mismatch between RE layers and Mn-O layers induces a simultaneous ferroelectric-trimerization structural phase transition [1]. Two distinct domain configurations have been observed in $REMnO_3$ (RE=rare earths): vortex domains vs. stripe domains [2]. However, the rapport between those topologically distinct domain patterns has never been studied. We have investigated the transformation process between vortex domains and stripe domains with the variation of temperature and the application of various strains on thin-plate-like crystals. [1] T. Choi *et al.*, Nature Mater. 9, 253 (2010). [2] S. C. Chae *et al.*, PRL 108, 167603 (2012).

11:39AM B21.00003 Ferroelectric domain formation and reversal by cation substitution in magnetoelectric gallium ferrite epitaxial thin films , R. H. SHIN, Ewha Womans University, CNRS-EWHA International Research Center, S. H. OH, W. JO[1], Ewha Womans University, C. LEFEVRE, Ewha Womans University, CNRS-EWHA International Research Center, Institute of Physics and Chemistry of Materials of Strasbourg, F. ROULLAND, A. THOMASSON, C. MENY, N. VIART, Institute of Physics and Chemistry of Materials of Strasbourg — Linear magnetoelectric $Ga_{2-x}Fe_xO_3$ (GFO) is ferrimagnet at room temperature (RT) (T_C =370 K at x=1.4) from Fe spin of d orbitals in octahedral Fe1(opposite direction), Fe2, and Ga2 sites along c-axis. According space group as $Pc2_1n$, ferroelectric ordering should be here along b-axis but have not observed, experimentally. Several scenarios of ferroelectricity in GFO have been suggested such as displacement of Fe ions, structural change, and so on. In the scenarios, it is very difficult to obtain their polarization because of tiny quantity and high domain wall (DW) formation energy. In this talk, we suggest the cation substituted GFO can be promising RT multiferroic showing ferroelectric ordering. We tried two kinds of direction: 1. Obtain polarization reversal under high magnetic and electric field to overcome high DW formation energy. 2. Apply chemical strain to make DW formation energy low. Though, when we applied chemical strain by substituting divalent cations, leakage current that overshadow polarization reversal was strongly reduced, ferromagnetic ordering was lost at RT owing to magnetic dilution by nonmagnetic cation like Mg^{2+}. Therefore, we discuss how to obtain ferroelectric polarization in the GFO thin films conserving RT ferrimagnet.

11:51AM B21.00004 Strong coupling of ferroelectricity and magnetism in the hexagonal ferrites , HENA DAS, School of Applied and Engineering Physics, Cornell University, Ithaca, NY, USA — During the last decade one of the most extensively studied class of multiferroics has been the hexagonal rare-earth manganites $RMnO_3$ where R=Dy-Lu, Y, Sc. These compounds exhibit antiferromagnetic (AFM) order with a Néel temperature $T_N \approx 100K$. In addition, they are improper ferroelectrics ($T_C > 1200K$) driven a by zone-tripling structural distortion associated with a buckling of the R-planes and a rotation of the oxygen trigonal bipyramids. The improper nature of the transition is responsible for the fascinating, topologically protected trimer-domains. Even though magnetism and ferroelectricity in these materials are not intrinsically coupled, there is a non-trivial interaction between the structural and magnetic domain walls. In contrast to the manganites, the ground state structure of the rare-earth ferrites $RFeO_3$ is the orthorhombic perovskite. Recently, however, thin films of $RFeO_3$ have been epitaxially stabilized in the hexagonal rare-earth manganite structure. This development has triggered several new studies of these hexagonal ferrite systems. Similar to manganites, ferrites exhibit ferroelectricity above room temperature and crystallize in $P6_3cm$ polar structure but conflicting results have been reported as to the origin of ferroelectricity in these materials. Unlike the manganites, recent neutron diffraction measurements suggest a considerably high AFM ordering temperature, T_N =440 K. Additionally there is an indication of a second temperature, $T_{wFM} \sim 100K$, at which weak ferromagnetism has been observed. In this work my collaborators (Alex Wysocki and Craig J. Fennie) and I address the nature of ferroelectricity and magnetic order in the $RFeO_3$ systems from first-principles. We elucidate the origin of ferroelectricity in the rare-earth ferrites and provide many useful insights into their magnetic behavior, which we will show is fundamentally different than that observed in the manganites. Combining first-principles calculations with a detailed modeling of the magnetic structure we will also show how this difference leads to an interplay between ferroelectricity and magnetism in the ferrites. This strong coupling, absent in the hexagonal manganites, manifests itself in a nontrivial way that may be useful for voltage controlled magnetic functionalities.

12:27PM B21.00005 Is hexagonal $InMnO_3$ ferroelectric? , FEI-TING HUANG, YOICHI HORIBE, XUEYUN WANG, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, SHIGEO MORI, Department of Materials Science, Osaka Predecture University — Hexagonal manganite (h-$REMnO_3$; RE=rare earths) shows a unique improper ferroelectricity, accompanying a structural trimerization. RE can be replaced by In, which is much smaller than any RE ions. Recently, Oak *et al.* [1] suggested $InMnO_3$ is ferroelectric from the results of first-principles calculations, while Kumagai *et al.* [2] proposed a non-ferroelectric ground state. In this talk, we will report the results of our investigation on the structural domains and local structural distortions of $InMnO_3$ using dark-field transmission electron microscopy. We demonstrate that $InMnO_3$ shows a distinct $\sqrt{3} \times \sqrt{3}$-type superstructure from the high-temperature paraelectric phase ($P6_3/mmc$), and the domain structure can be delicately controlled by varying the synthesis and annealing conditions. The correlation between physical properties and local structural distortions in the $InMnO_3$ will be discussed in detail. [1] M.-A. Oak, J.-H. Lee, H. M. Jang, J. S. Goh, H. J. Choi and J. F. Scott, PRL **106**, 047601 (2011). [2] Y. Kumagai, A. A. Belik, M. Lilienblum, N. Leo, M. Fiebig, and N. A. Spaldin, PRB **85**, 174422 (2012).

12:39PM B21.00006 Far- and mid-infrared emission and reflection of magnetoelectric $RMnO_3$ and $RCrO_3$ (R=Rare Earth) , NESTOR E. MASSA, LANAIS EFO-CEQUINOR, UNLP, La Plata, Argentina, LEIRE DEL CAMPO, DOMINGOS DE SOUSA MENESES, PATRICK ECHEGUT, CNRS-CEMHTI, Orléans, France, MARIA JESUS MARTINEZ-LOPE, JOSE ANTONIO ALONSO, ICMM-CSIC, Madrid, Spain — Far- and mid-infrared emission and reflection spectra of ferrielectric hexagonal $TmMnO_3$ show that small polarons, a paramagnetic collective electronic mode, and lower than T_N soft hybrid modes are in concomitant relation. CO_2 laser heating in dry air triggers oxidation and Mn^{3+}- Mn^{4+} double exchange hopping conductivity. A collective excitation in the paramagnetic phase is assigned to e_g electrons in THz low energy d-orbital fluctuations. It locks-in at the E-type antiferromagnetic onset ($T_N \sim 80K$) into soft bands that harden simultaneously down to 4 K with temperature dependence given by the magnetic long range order coupling of the collective electric dipole. They have T_N as critical temperature and critical exponents suggesting a second order phase transition. They also match zone center spin wave modes measured in isomorphous $LuMnO_3$ (Lewtas et al, Phys. Rev. B **82**, 184420 (2010)). Both excitations, magnons y electric dipoles, are generated by electrons e_g in deformed d-orbitals. Sharing this behavior with orthorhombic $NdMnO_3$ there is no evidence of new phonons in a structural deformation down to 4K Preliminary results in $ErCrO_3$ ($T_N \sim 130$ K) show the emerging soft bands in an order-disorder scenario. Overall, we conclude that magnetoelastic deformations in an orbital fluctuating environment are close related to magnetoelectric couplings.

12:51PM B21.00007 Synthesis, Structural Characterization and Magnetic Properties of $YbFe_{1-x}Mn_xO_3$ ($0.0 \leq x \leq 1.0$) Perovskites , C. HERNANDEZ, E. CHAVIRA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, AP 70-360, 04510 México D. F., México, I. ROSALES, Facultad de Quimica, Universidad Nacional Autónoma de México, AP 70-360, 04510 México D. F., México, A. TEJADA, L. HUERTA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, AP 70-360, 04510 México D. F., México, E.E. MARINERO, HGST San Jose Research Center — We report on the synthesis, structural characterization and magnetic properties of $YbFe_{1-x}Mn_xO_3$ ($0.0 \leq x \leq 1.0$) perovskites. Compounds with x= **0, 0.2, 0.4, 0.6, 0.8 and 1.0** were synthesized by solid state reaction. We find that the perovskites with x=0, 0.2 exhibit an orthorombic crystalline structure, whereas those with x=0.6, and 1.0 are hexagonal. A mixture of both hexagonal and orthorhombic phases are observed for x= 0.4 and 0.8. The magnetic properties of these materials have been studied as a function of temperature (2K – 300K). In the low temperature regime (2K – 30K), we observe previously unreported magnetic transitions whose transition temperature depends on the amount of Mn incorporated in the perovskite. We will describe the possible origin of these magnetic transitions in terms of the structural properties of the materials studied.

1:03PM B21.00008 Crystal Structure, Electric Polarization and Heat Capacity Measurements on Small R-Ion Multiferroic Hexagonal $RMnO_3$, TIAN YU, PENG GAO, TAO WU, TREVOR TYSON, New Jersey Institute of Technology, ROGER LALANCETTE, Rutgers University — Crystal structure, electric polarization and heat capacity measurements on the hexagonal multiferroic $RMnO_3$ reveal that small R ion (Lu and lower cation size) systems are ferroelectric and possess the same space-group as $YMnO_3$. Combined local and long range structural measurements were conducted by XAFS, PDF and single crystal and powder XRD methods. The influence of the Mn-O and R-O distribution on the electric polarization is discussed. Point charge estimates of the electrical polarization are given for comparison with the $YMnO_3$ system. This work is supported by DOE Grant DE-FG02-07ER46402.

1:15PM B21.00009 Temperature Dependent Properties of Perovskite Small R-Ion $RMnO_3$ Systems[1] , HAIYAN CHEN, TIAN YU, PENG GAO, TREVOR TYSON, KEUN HYUK AHN, New Jersey Institute of Technology — Perovskite small ion E-type systems with radii smaller than that of Lu have been synthesized. The structure, heat capacity and magnetic measurements have been used to compare them with standard E-type systems such as $LuMnO_3$ and $HoMnO_3$. Analysis of the structure is combined with theoretical estimates to relate the electronically driven polarization with the atomic structure.

[1]This work is supported by DOE Grant DE-FG02-07ER46402.

1:27PM B21.00010 Critical Structural Parameters Influencing Magnetic Transition Temperatures in Multiferroic Hexagonal $RMnO_3$[1] , TREVOR TYSON, TIAN YU, TAO WU, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07102, CATHERINE DUBOURDIEU, 2INL, CNRS - Ecole Centrale de Lyon,Ecole Centrale de Lyon, 36 avenue Guy de Collongue, 69134 Ecully, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy & Rutgers University, Piscataway, NJ 08854 — Multiferroic hexagonal $RMnO_3$ systems with a broad range of transition temperatures and including some with spin rotation transitions have been studied. Detailed temperature depended structural measurements have been conducted to extract the static and dynamic changes. The structural measurements are combined with qualitative theoretical arguments to determine the critical parameters which influence the magnitude of the magnetic ordering temperature. Suggestion are made on ways to optimize it to enable higher temperature multiferroic behavior.

[1]This work is supported by DOE Grant DE-FG02-07ER46402.

1:39PM B21.00011 Insights on Electric Polarization in E-type $R\mathbf{MnO}_3$, TAO WU, TREVOR A. TYSON, HAIYAN CHEN, New Jersey Institute of Technology, ZHIQIANG CHEN, Stony Brook University, RYAN TAPPERO, Brookhaven National Laboratory, KEUN H. AHN, New Jersey Institute of Technology, SUNGBAEK KIM, SANG-WOOK CHEONG, Rutgers University — Orthorhombic perovskite E-type $R\mathrm{MnO}_3$ multiferroic systems were prepared by high pressure synthesis and solid state reaction. High pressure synchrotron x-ray diffraction and x-ray absorption spectroscopy measurements were performed to explore the structural changes. The influence of the pressure on the electrical polarization is discussed. Theoretical analysis is used to predict pressure dependence of the polarization from the structural data derived from the refinements. This work is supported by DOE Grant DE-FG02-07ER46402.

1:51PM B21.00012 Ferroelectric and ferromagnetic properties of $\mathbf{Ga_x\ CoFe_{2-x}O_4}$ /$\mathbf{BaTiO_3}$, YAN NI, Department of Electrical and Computer Engineering, Iowa State University, Iowa, Ames, USA, CAJETAN NLEBEDIM, Ames Laboratory, US DOE, Iowa State University, DAVID JILES, Department of Electrical and Computer engineering, Iowa State University, Iowa, Ames, USA — Single phase magnetoelectric materials are limited in application. Consequently, practical application of magnetoelectric materials requires the development of composite materials in which piezoelectric and magnetostrictive phases are coupled via interfacial strain. In addition to strong coupling, it is desirable that both the magnetostrictive and piezoelectric phases possess high sensitivity, $d\lambda/dH$ and $dP/d\sigma$ respectively. Of all the substituted cobalt ferrite studies, CoGaxFe2-xO4 has been shown to have the highest strain sensitivity. In the present study, CoGaxFe2-xO4 (x=0.1, 0.2, 0.3) has been combined with BaTiO3 to fabricate a y(CoGaxFe2-xO4)-(1-y)BaTiO3 (y = 0.4, 0.5 and 0.6) magnetoelectric composite samples. Crystal structure, microstructure and compositions of the samples were verified by XRD, SEM and EDX. The effect of the BaTiO3 phase on the magnetostrictive properties of CoGaxFe2-xO4 and the effect of the CoGaxFe2-xO4 phase on the piezoelectric properties of BaTiO3 will be presented with respect to the magnetoelectric properties of the composites.

Session B22 DCMP: Nano Particles, Wires, and Cavities 324 - Sergio Ulloa, Ohio University

11:15AM B22.00001 Optical properties and circular dichroism of chiral metal nanoparticles[1] , ZHIYUAN FAN, ALEXANDER GOVOROV, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, OU TEAM — In nature, biological systems are built up by homochiral building blocks, such as a sugar and protein. Circular dichroism (CD) is an effective tool of resolving molecular conformations. It utilizes circularly polarized light to detect differential absorption of chiral materials. In medicine, it will help us to develop new drugs and therapies, if we understand the connection between the physical or chemical properties of drug molecules and their conformations. With the rapid development of nanotechnologies, chiral nanomaterials attract lots of attention nowadays. CD signals of chiral molecules can be enhanced or shifted to the visible band in the presence of plasmonic nanocrystals. Here we present a plasmonic CD mechanism from a single chiral metal nanocrystal[1]. The mechanism is essentially different from the dipolar plasmon-plasmon interaction in a chiral NP assembly[2], which mimics the CD mechanism of chiral molecules. Chiral metal nanocrystals are expected to have promising applications in biosensing. Recently a few experimental papers reported successful realizations of chiral nanocrystals in a macroscopic ensemble in solution. Particularly the paper[3] described silver nanoparticles grown on chiral template molecules and demonstrating characteristic CD signals at a plasmonic wavelength. The plasmonic CD signals in Ref.[3] can come from a dipolar plasmon-molecule interaction or from a chiral shape of nanocrystals. [1] Z.Fan, et al. Nano Lett.,12, 3283 (2012). [2] A. Kuzyk, et al., Nature 483, 311 (2012). [3] B.Maoz, et al. J. Am. Chem. Soc.134, 17807 (2012).

11:27AM B22.00002 Transport measurements across single nanoparticles , QIAN YU, LIMIN CUI, Laboratoire de Physique et d'Etude des Matériaux, UMR 8213, ESPCI-ParisTech-CNRS-UPMC, 10 rue Vauquelin, 75231 Paris, France, CHRISTIAN ULYSSE, Laboratoire de Photonique et de Nanostructures, CNRS, Marcoussis, France, ALIREZA MOTTAGHIZADEH, ALEXANDRE ZIMMERS, HERVÉ AUBIN, Laboratoire de Physique et d'Etude des Matériaux, UMR 8213, ESPCI-ParisTech-CNRS-UPMC, 10 rue Vauquelin, 75231 Paris, France — During this last decade, numerous progresses have been obtained in the chemical synthesis of nanoparticle. Various materials (oxides, chalcogenides) known for their peculiar electronic or magnetic properties – superconductivity, Mott localization, topological protection – can now be obtained as nanoparticles through chemical synthesis. These new nanomaterials are offering a unique opportunity to study the effect of quantum confinement on unconventional electronic orders. To improve the preparation of samples with single nanoparticles trapped within a nanogap, we developed a new method where nanoparticles are projected in-vacuum on chip circuits covered by nanogap spaced electrodes. Continuous current measurements during the projection allow identifying the trapping of a single nanoparticle within the nanogap. We apply the method for trapping single gold nanoparticles, which led to the observation of Coulomb blockade. We also applied the method to magnetite (Fe3O4) nanoparticles, which allows to study the electric field induced insulator to metal transition in only a few nanoparticles.

11:39AM B22.00003 Characterization of TbAs nanoparticles embedded in GaAs using pump-probe measurements of carrier relaxation dynamics , LAURA R. VANDERHOEF, University of Delaware, ABUL K. AZAD, DIBAKAR R. CHOWDHURY, Los Alamos National Laboratory, CORY BOMBERGER, JOSHUA M. O. ZIDE, MATTHEW F. DOTY, University of Delaware — Rare-earth-monopnictide nanoparticles epitaxially deposited within III-V semiconductors have been shown to improve the performance of devices for applications ranging from thermoelectrics to THz pulse generation. However, the electronic structure of small (approximately 1.5 nm diameter) TbAs nanoparticles remains poorly understood. We use ultrafast pump-probe spectroscopy to investigate the electronic structure of the TbAs nanoparticles. The samples studied were grown by co-deposition of Tb, Ga, and As on a GaAs substrate, resulting in TbAs nanoparticles embedded within a GaAs host. We study the dynamics of carrier relaxation into the TbAs states, which essentially act as traps, using both optical-pump terahertz-probe and optical-pump optical-probe techniques. By analyzing how the carrier relaxation rates depend on both pump fluence and sample temperature we conclude that the TbAs states are saturable, which suggests the existence of a bandgap for TbAs nanoparticles.

11:51AM B22.00004 Optical and electronic properties of self-assembled nanoparticle-ligand metasurfaces[1] , JAKE FONTANA, Naval Research Laboratory, JOHN LIVENERE, Norfolk State University, JOSHUA CALDWELL, CHRISTOPHER SPILLMANN, JAWAD NACIRI, RONALD RENDELL, BANAHALLI RATNA, Naval Research Laboratory — The optical and electronic properties of inorganic nanoparticles organized into two-dimensional lattices sensitively depend on the properties of the organic ligand shell coating the nanoparticles. We study the optical and electronic properties of these two-dimensional metasurfaces consisting of gold nanoparticles functionalized with ligands and self-assembled into macroscopic monolayers on non-templated substrates. Using these metasurfaces we demonstrate an average surface-enhanced Raman scattering (SERS) enhancement factor on the order of 10^8 for benzenethiol ligands and study the mechanisms that influence the enhancement. These metasurfaces may provide a platform for the development of low-power, low-cost next-generation chem/bio-sensors and new insights into the organic-inorganic interface at the nanoscale.

12:03PM B22.00005 Two photon excitation fluorescence from Ag nanotriangles and nanohexagons , CHI-YU JAO, Virginia Tech, BRENDEN MAGILL, Institute for Critical Technology and Applied Science at Virginia Tech, HANS ROBINSON, Virginia Tech — We report on measurements of two photon excitation fluorescence (TPEF) from arrays of silver nanotriangles and nanohexagons fabricated by nanosphere lithography. The silver nanoparticles exhibit localized surface plasmon resonances (LSPRs) that depend on the size, shape and aspect ratio of the particles. When the particles are excited by femtosecond pulsed laser light resonant with the LSPRs, they emit TPEF with significantly higher intensity than when excited off resonance. Moreover, if the light intensity is turned up sufficiently to cause some of the particles to melt into spherical particles, we observed an increase in the TPEF from the spheres by as much as an order of magnitude, even though their LSPRs are no longer resonant with the laser. Finally, we note that the silver particles also generate light at the second harmonic of the laser frequency, although the efficiency of this process depends strongly on the dielectric environment of the silver particles, which is not the case for the TPEF.

12:15PM B22.00006 Investigation of the electronic transport in polarization-induced nanowires using conductive atomic force microscopy (AFM) , CAMELIA SELCU, SANTINO C. CARNEVALE, THOMAS F. KENT, FATIH AKYOL, PATRICK J. PHILLIPS, MICHAEL J. MILLS, SIDDHARTH RAJAN, JONATHAN P. PELZ, ROBERTO C. MYERS, The Ohio State University — In the search to improve short wavelength light emitting diodes (LED's), where the dislocations limit their performance and hole doping (Mg) is a fundamental challenge, the III-Nitride polarization-induced nanowire LED provides a promising system to address these problems. The new type of pn diode, polarization-induced nanowire LED (PINLED), was developed by linearly grading AlGaN composition of the nanowires (from GaN to AlN and back to GaN) from 0% to 100% and back to 0% Al (Carnevale et al, *Nano Lett.*, **12**, 915 (2012)). In III-Nitrides (Ga,Al/N), the effects of polarization are commonly observed at the surfaces and interfaces. Thus, in the case of the polarization-induced nanowire LEDs, taking advantage of the bound polarization charge, due to the grading of the AlGaN, the pn diodes are formed. The polarity of the nanowires determines the carrier type in each graded region, and therefore the diode orientation (n/p vs p/n). We used conductive AFM to investigate polarity of the PINLED's as well as hole conductivity in PINLED's made of AlGaN with and without acceptor doping. The results reveal that most of the wires are n-top/p-bottom (N-face), but some are p-top/n-bottom (Ga-face). Also, we found that the current density is 3 orders of magnitude larger in the case of the doped nanowires than the nanowires with no impurity doping.

12:27PM B22.00007 Critical Role of Modal Spatial Overlap in Nanoscale Nonlinear Optics , JIMIN ZHAO, RUI WANG, BEN-LI WANG, R.J. LIU, X.H. LU, ZHI-YUAN LI, Institute of Physics, Chinese Academy of Sciences — We unambiguously demonstrate the critical role of modal spatial overlap in *nonlinear* optics for nanoscale structures. Our experimental and theoretical investigations show that, within a sub-wavelength metallic hole, spatial overlap between the linear and nonlinear modes strongly correlates to the conversion efficiency. Our results provide an accurate explanation for the long-emphasized but elusive shape effect. Moreover, our investigation stimulates new angles for and deeper insights into general nonlinear optics at nanoscale.

12:39PM B22.00008 Nanocluster effects on magneto-resistance and optical second-harmonic generation in Au-Co composite films , KAIDA YANG, Department of Applied Science, College of William and Mary, TATIANA MURZINA, Quantum Electronics division, Department of Physics, Moscow State University, ALE LUKASZEW, Department of Physics, College of William and Mary — Magnetic nanomaterials typically exhibit significant differences in their magnetic and magnetic-optical properties compared to bulk. A viable nanoscale platform to investigate the magnetic and magneto-optical properties of magnetic nanomaterials is in composite thin films to have magnetic clusters embedded on a different matrix material which size can be tailored. The Au-Co binary system is a typical phase-separation system in bulk phase diagram . The nanocomposite geometry allows tailoring the actual composition and microstructure of the composite by exploiting different temperature during deposition. In our previous studies, Au/Co/Au trilayers as well as Au-Co nanocomposite thin films exhibit strong enhancement of the magneto-optical activities due to surface plasmon polariton excitation in the noble metal. In this study, we investigate other non-linear optical properties such as second harmonic generation (SHG) in Au-Co nanocomposite thin films and understand its correlation with the magneto-transport properties of the composite. Optical SHG is a sensitive probe of surface and buried interfaces due to inversion symmetry breaking at the interfaces of centrosymmetric materials which allows probing of the structural and morphological properties near interfaces.

12:51PM B22.00009 Far-infrared transmission through periodic arrays of cross-shaped holes , LUYI YAN, CHANG LONG, DAVID TANNER, University of Florida, N. BRADMAN, N. MCFARLAND, J.B. MARBRUGER, Advanced Plasmonics Inc. — The far-infrared transmission of light incident on a free-standing metal film perforated with periodic cross-shaped holes is investigated. These metal-mesh filters show enhanced "extraordinary" infrared transmission at particular wavelengths. A number of filter samples having different periodicities and geometries have been measured over frequencies from 20-650 cm^{-1}/0.6-19.5 THz. The results will be compared with calculations from surface plasmon polariton (SPP) theory. It is shown that for certain periodicity and geometry, the SPP mode and the localized surface plasmon (LSP) mode may have their resonance peaks nearly superimposed on each other. The bandwidth of this transmission peak is related to the ratio of the width and length of the cross-shaped holes. The correlation between transmission properties and the incident angle of the far-infrared light has also been measured for both polarization conditions. As the incident angle is increased, the transmission peak shows a blue shift when illuminated by s-polarized light, while for p-polarized light it splits into two parts which shift in opposite directions.

1:03PM B22.00010 ABSTRACT WITHDRAWN –

1:15PM B22.00011 Time-resolved nonlinear dynamics of quantum dots coupled to a photonic crystal cavity in the Purcell regime , JIEUN LEE, TIMOTHY SAUCER, Department of Physics, University of Michigan, ANDREW MARTIN, JOANNA MILLUNCHICK, Department of Materials Science and Engineering, University of Michigan, VANESSA SIH, Department of Physics, University of Michigan — Recently, there has been great interest in studying the optical nonlinearities of light confined in a solid-state nano-cavity interacting with a quantum emitter for on-chip applications. The nonlinearity in the strong coupling regime has enabled ultrafast all-optical switching at low incident power using exciton-photon coupled systems. In this report, we show that nonlinear optical properties can also be observed in the Purcell regime using a cavity with a moderate quality factor (Q), which arises from the saturation of a single quantum dot and describes the time-resolved dynamics of two transitions (exciton and biexciton) exhibiting different nonlinearities. In order to conduct these investigations, we used the luminescence intensity autocorrelation method and measured the variation of nonlinear emission dynamics while varying the incident power over nearly three orders of magnitude and found excellent agreement with a numerical simulation. We expect the method and the theoretical model will be applicable for understanding other nonlinear effects such as lasing and cavity-QED.

1:27PM B22.00012 Entangled photons from the polariton vacuum in a switchable optical cavity , ADRIAN AUER, GUIDO BURKARD, Department of Physics, University of Konstanz, Germany — We study theoretically the entanglement of two-photon states in the ground state of the intersubband (ISB) cavity system, called polariton vacuum. The system is formed by a sequence of quantum wells (QWs) located inside a microcavity and the interaction of cavity photons with ISB excitations inside the QWs leads to the formation of polariton states. In the ultrastrong coupling regime, the polariton vacuum already contains a finite number of photons, of which pairs with opposite in-plane wave vectors are correlated. In an explicit solution for the polariton vacuum, we only consider certain two-photon states by post-selection and analyze them for mode entanglement, i.e. in the momentum degree of freedom. We find an analytical expression for the entanglement using the concurrence [1], which depends on the absolute values of the in-plane wave vectors of the photons. In the limit of large cavities and for photon energies around the ISB resonance in the mid infrared regime, the photons are almost maximally entangled, which is fundamentally important for their possible use in quantum information processing. Furthermore, there exists a continuous set of mode pairs, for which the photons are maximally entangled.

1:39PM B22.00013 Coherent flow and Bose-Einstein Condensation of Long Lifetime Polaritons[1] , GANGQIANG LIU, BRYAN NELSON, MARK STEGER, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, RYAN BALILI, Department of Physics, MSU-Iligan Insititute of Technology, Iligan, 9200, Philippines, DAVID SNOKE, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, KEN WEST, LOREN PFEIFFER, Department of Electrical Engineering, Princeton University, NJ 08544, USA — Exciton-polaritons with lifetimes of the order of 100ps are created in semiconductor microcavity of extremely high quality factor (? 106). Due to this long lifetime and very few defects in the sample, the polaritons can travel ballistically over macroscopic distances up to millimeter. The properties of the system changes dramatically with the particle density. At moderate density, the polaritons behave like a superfluid, maintaining phase coherence after propagating over hundreds of microns. This indicates the existence of long range spatial coherence in the system. As the density increases above a threshold value, the polaritons condense into the lowest-energy state of the effective trap produced by the repulsive interaction between the polaritons and excitons within the excitation region and the cavity gradient across the sample. The coherence time of this polariton BEC is measured to be at least 280ps. By creating a exciton barrier at the center of a stress trap, we are able to obtain a ring shape polariton BEC which provides the opportunity for studying the constant flow of a superfluid in the polariton system.

Session B23 FIAP: Focus Session: Dopants and Defects in Semiconductors II 325 - Gerd J. Duscher, University of Tennessee at Knoxville

11:15AM B23.00001 A modification of Eu incorporation sites by the dissociation of hydrogen defect complexes in Mg co-doped Eu doped gallium nitride , BRANDON MITCHELL, Lehigh University, JONATHAN POPLAWSKY, Oakridge National Lab, VOLKMAR DIEROLF, Lehigh University — Europium doped gallium nitride (Eu:GaN) is a promising candidate as a material for red LEDs that can monolithically be integrated with existing nitride based lighting technology. Photoluminescence (PL) and cathodoluminescence (CL) studies have revealed, however, that the majority incorporation environment (site) for the Eu is not efficiently excited by electron hole pairs. To improve this efficiency, Mg was co-doped into Eu:GaN during metal organic chemical vapor deposition and multiple new incorporation environments were discovered. These new sites show a high efficiency at room temperature and have been attributed to the coupling of a Mg-H complex to the majority Eu site. However, we also observe that sustained electron beam irradiation produced a semi-permanent change in the CL spectra of the sample. It was demonstrated that this change occurs in two distinct steps which exhibit a pronounced temperature dependence. Our observations point toward a dynamic system in which the Mg-H bond is broken and the hydrogen moves within the epi-layer. Details of this behavior will be discussed.

11:27AM B23.00002 The origin of the high hole density in $In_xGa_{1-x}N$:Mg[1] , WILLIAM WILLOUGHBY, MARY ELLEN ZVANUT, University of Alabama at Birmingham — InGaN is the nitride of choice for applications requiring high hole density and emission tunability. The increased hole density with In incorporation may be explained by several different mechanisms; however, our electron paramagnetic resonance (EPR) studies reveal a surprising feature: the number of Mg-related acceptors decreases with increasing hole density. $In_xGa_{1-x}N$ films, with x between 0.02 and 0.11 and thickness between 0.25 and 0.44 μm, were grown p-type by doping with Mg to a concentration of 2-3 $\times$ 10^{19} cm^{-3}. Hall measurements reveal the expected hole density increase from 5-30x10^{17} cm^{-3} with increasing In mole fraction. However, unlike GaN:Mg where the EPR Mg signal tracks the hole density, the EPR intensity of the Mg-related signal in InGaN is found to decrease as the hole density increases. Together, compensating defects and a lowering of the acceptor level may explain the decrease in EPR intensity and the increase in hole density observed as the In mole fraction is increased.

[1]Dr. D. Koleske grew the samples and performed the Hall measurements. The work is supported by the National Science Foundation, DMR-1006163.

11:39AM B23.00003 Stability and electronic structure of Mg dopants in InGaN alloys , JI-SANG PARK, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology — Nitride semiconductors have attracted much attention due to their applications for light emitting and laser diodes. High conductivity p-type nitride layers are demanding for various optoelectronic devices, however, hole concentrations are generally low because of the deep acceptor level of Mg and the compensation of hole carriers by donor defects. In this work, we investigate the stability and electronic properties of Mg dopants in InGaN alloys through first-principles density functional calculations. We generate the alloy structure with the In content of 10% by using the special quasi-random structure approach. Considering various Mg sites surrounded with different numbers of the In atoms in the second nearest neighborhood, we find that Mg dopants prefer to be located near the Ga atoms rather than the In atoms due to the local bonding effect. Incorporation of the In atoms not only reduces the band gap but also decreases the ionization energy of Mg in Ga-rich regions. However, the ionization energy tends to increase as the number of the In atoms in the second nearest neighborhood increases, although this configuration is energetically unfavorable.

11:51AM B23.00004 How localized acceptors limit p-type conductivity in GaN[1] , JOHN L. LYONS, Materials Department, University of California, Santa Barbara — Despite the impressive development of GaN as an optoelectronic material, p-type conductivity is still limited. Only a single acceptor impurity, magnesium, is known to lead to p-type GaN. But Mg is far from a well-behaved acceptor. Hydrogen is known to passivate Mg, necessitating a post-growth anneal for acceptor activation. In addition, the ionization energy is quite large ($\sim$ 200 meV in GaN), meaning only a few percent of Mg acceptors are ionized at room temperature. Thus, hole conductivity is limited, and high concentrations of Mg are required to achieve moderately p-type GaN. Other acceptor impurities have not proven to be effective p-type dopants, for reasons that are still unresolved. Using advanced first-principles calculations based on a hybrid functional, we investigate the electrical and optical properties of the isolated Mg acceptor and its complexes with hydrogen in GaN, InN, and AlN.[2] We employ a technique that overcomes the band-gap-problem of traditional density functional theory, and allows for quantitative predictions of acceptor ionization energies and optical transition energies. Our results allow us to explain the deep or shallow nature of the Mg acceptor and its relation to the optical signals observed in Mg-doped GaN. We also revisit the properties of other group-II acceptors in GaN. We find that all cation-site acceptors show behavior similar to Mg_{Ga}, and lead to highly localized holes. The Zn_{Ga} and Be_{Ga} acceptors have ionization energies that are even larger than that of Mg, making them ineffective dopants. All acceptors cause large lattice distortions in their neutral charge state, in turn leading to deep, broad luminescence signals that can serve as a means of experimentally verifying the deep nature of these acceptors.

12:27PM B23.00005 Role of self-trapping in luminescence and p-type conductivity of wide-band-gap oxides[1] , JOEL VARLEY, Stanford University, ANDERSON JANOTTI, University of California, Santa Barbara, CESARE FRANCHINI, University of Vienna and Center for Computational Materials Science, CHRIS VAN DE WALLE, University of California, Santa Barbara — Using hybrid functional calculations, we investigate the behavior of holes in the valence band of a range of wide-band-gap oxides including ZnO, MgO, In_2O_3, Ga_2O_3, Al_2O_3, SnO_2, SiO_2, and TiO_2. We find that, due to the orbital composition of the valence band, holes tend to form localized small polarons with characteristic lattice distortions, even in the absence of defects or impurities. These self-trapped holes (STHs) are energetically more favorable than delocalized, free holes in the valence band in all materials but ZnO and SiO_2. Based on calculated optical absorption and emission energies we show that STHs provide an explanation for the luminescence peaks that have been observed in many of these oxides. Additionally, we demonstrate that polaron formation prohibits p-type conductivity in this class of materials.

[1]This work was supported by the NSF MRSEC Program (DMR05-20415).

12:39PM B23.00006 Carbon Defect Complex as a Source of Yellow Luminescence in GaN , DENIS DEMCHENKO, MIKHAIL RESHCHIKOV, Virginia Commonwealth University — Using hybrid functional theory compared with experimental measurements, we demonstrate that yellow luminescence often observed in both carbon-doped and pristine GaN is the result of electronic transitions via C_N-O_N complex. In contrast to the common isolated defects, C_N-O_N complex is energetically favorable, and its calculated optical properties as well as the thermodynamic transition level show excellent agreement with the measured luminescence data. Calculated transitions via the localized defect states of this complex are (experimental values are given in brackets): thermodynamic transition level of 0.75 eV (0.85 eV), absorption energy 3.30 eV (3.32 eV), emission energy 2.25 eV (2.20 eV), and zero phonon transition 2.70 eV (2.60 eV). This complex has not been proposed as a source of the yellow band in GaN, while all other defects previously suggested to be sources of this band exhibit high formation energies and would produce red or infrared photoluminescence. Thus, combining hybrid density functional theory and experimental measurements we propose a solution to a long-standing problem of the GaN yellow luminescence.

12:51PM B23.00007 Identification of the defect responsible for current collapse in GaN/AlGaN HEMTs , YEVGENIY PUZYREV, XIAO SHEN, SOKRATES PANTELIDES, Vanderbilt University, VANDERBILT PHYSICS TEAM — Recent experiments show that GaN/AlGaN high-electron-mobility transistors (HEMTs) suffer significant current collapse during stress conditions characterized by the presence of charge trap level $\sim$ 0.50 eV below conduction band. This phenomenon has been attributed to thermally activated defect diffusion without specifying responsible defects. Here we report first-principles density-functional calculations of the hydrogenated substitutional oxygen complexes and show that the electric-field-enhanced formation of this defect complex provides an explanation for observed phenomenon.

1:03PM B23.00008 Fe charge state kinetics in semi-insulating Fe-doped GaN[1] , USTUN SUNAY, Author/ presenter, JAMIYANAA DASHDORJ, Author/ Co-author, MARY ELLEN, Co-author / Advisor, KEVIN UDWARY, JACOB LEACH, Co-author/ grew samples — GaN is a wide bandgap semiconductor with applications in LEDs and high-power devices. One of the problems plaguing this material is a high concentration of residual donors. This issue can be resolved by doping GaN with deep acceptors such as Fe, which compensates donors and creates semi-insulating material. Recently, a photo-induced electron paramagnetic resonance (EPR) spectroscopy study of Fe-doped GaN showed significantly long relaxation times [1]. The study proposed a charge transfer mechanism between Fe^{3+} and Fe^{4+} as an explanation for the phenomenon. However, absorption data from the same samples showed the existence of both Fe^{2+} and Fe^{3+} which suggests that the proposed model involving Fe^{4+} is incorrect and a theory involving an intermediate center is more likely. 3.5 K 10 GHz EPR was performed on HVPE grown free-standing Fe/Si co-doped GaN. Data show an unexpected situation where both donor and Fe^{3+} acceptor signals exist simultaneously. Together with the photo-EPR results, these data reinforce the necessity of invoking a multi-step mechanism for compensation. A model for compensation based on charge transfer between Fe3+ and a donor will be described based on EPR and additional material characterization measurements.

1:15PM B23.00009 ABSTRACT WITHDRAWN –

1:27PM B23.00010 Nonradiative carrier capture rates at defects from first-principles calculations , QIMIN YAN, AUDRIUS ALKAUSKAS, CHRIS G. VAN DE WALLE, Materials Department, University of California at Santa Barbara — We develop a computational methodology to determine nonradiative carrier capture rates at defects in wide-band-gap semiconductors. In our theoretical framework, we consider carrier capture via multiphonon emission as the dominant nonradiative mechanism for deep defects in wide-band-gap materials at low and moderate carrier densities. Our methodology is based on the static approximation for the electron-phonon coupling. We employ a state-of-the-art hybrid density functional approach to describe the electronic structure. For charged defect systems, the screening effect by excess carriers is taken into account. As test cases, we investigate deep centers including C_N and V_{Ga} in GaN and Li_{Zn} in ZnO. Calculated carrier capture rates are in good agreement with available experimental data. This work was supported by DOE, NSF, Swiss NSF, and by the UCSB SSLEC.

1:39PM B23.00011 Optical properties of $Ga_{1-x}Mn_xAs$ from large scale ab initio calculations , J. JACKSON, R. CARDENAS, G. BESTER, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany. — The properties of Mn impurities in GaAs are revisited employing a new methodology based on atomic effective potentials (AEPs [1]) which yields LDA accuracy at considerably reduced computational expense. We consider the case of very low Mn concentrations that cannot be considered using conventional ab initio methods and discuss the metal/insulator transition in terms of the Mn-d band localization and its interpretation as a shallow acceptor. We discuss practical methods to improve upon the LDA bandgap in GaAs together with the excessive delocalization of the Mn states. Using a configuration-interaction technique we calculate the optical spectra of $Ga_{1-x}Mn_xAs$ including the fine-structure (FSS) splitting which is of importance to the development of quantum computing devices based upon magnetic impurities in semiconductors [2].

1:51PM B23.00012 Impact of gamma-irradiation on the properties of n-type AlGaN/GaN heterostructures , ELENA FLITSIYAN, LEONID CHERNYAK, University of Central Florida — Gamma-photon irradiation of AlGaN/GaN HEMTs with the modest dose of 700 Gy* resulted in significant deterioration of their DC characteristics. To understand the nature of the observed effect, we carried out a series of variable temperature EBIC measurements in the vicinity of HEMT's gate in-situ in Scanning Electron Microscope. The measurements were performed on 3 different devices, which were exposed to various gamma-irradiation doses. Temperature dependent EBIC measurements allowed obtaining activation energies for levels in the material's forbidden gap, which are responsible for carrier recombination. While the diffusion length decreases significantly with increasing irradiation dose, the activation energy, associated with carrier recombination, gets larger. This fact indicates generation of new deep levels caused by gamma-photon irradiation. These levels act as traps for electrons in AlGaN/GaN HEMT channel, thus reducing the drain current and leading to degradation of other device characteristics. The investigated effects of gamma irradiation are likely related to, epitaxial layer quality and composition. Therefore, the study of materials with variations in these properties is necessary to fully understand the irradiation-induced mechanisms.

2:03PM B23.00013 Electronic band structure, doping, and defects in the semiconducting Half Heusler compound CoTiSb[1] , JASON KAWASAKI, University of California Santa Barbara, LINDA JOHANSSON, MARTIN HJORT, RAINER TIMM, Lund University, BRIAN SCHULTZ, University of California Santa Barbara, THIAGARAJAN BALASUBRAMANIAN, ANDERS MIKKELSEN, Lund University, CHRIS PALMSTROM, University of California Santa Barbara — We report transport and electronic band structure measurements on epitaxial films of the Half Heusler compound CoTiSb. CoTiSb belongs to the family of Half Heuslers with 18 valence electrons per formula unit that are predicted to be semiconducting despite being composed of all metallic components. Here the CoTiSb films were grown by molecular beam epitaxy on a lattice matched InAlAs buffer. The films are epitaxial and single crystalline, as measured by reflection high-energy electron diffraction and X-ray diffraction. Scanning tunnelling spectroscopy and temperature-dependent transport measurements reveal that the films are semiconducting, with unintentionally doped carrier concentrations comparable to that of highly doped conventional compound semiconductors. These carrier concentrations can be modulated by doping with Sn. The band structure of the films was measured by angle resolved photoemission spectroscopy at the MAX-Lab Synchrotron facility. The bulk bands are in general agreement with density functional theory calculations, with a valence band maximum at Γ and surface states within the bulk band gap. The effects of defects are explored in order to explain the ARPES results.

Session B24 GSCCM DCOMP DMP: Focus Session: Materials in Extremes: High-Strain-Rate Phenomena 326 - Igor Schweigert, Naval Research Laboratory

11:15AM B24.00001 Iron and Aluminum at Ultrahigh Strain Rates , JONATHAN CROWHURST, Lawrence Livermore National Laboratory — In recent years, techniques based on table-top laser systems have shown promise for investigating dynamic material behavior at high rates of both compressive and tensile strain. Common to these techniques is a laser pulse (the "pump") that is used in some manner to rapidly deliver energy to the sample; while the energy itself is often comparatively very small, the intensity can be made high by tightly focusing the pump light. In this way pressures or stresses can be obtained that are sufficiently large to have relevance to a wide range of basic and applied fields. Inherent to these techniques too, is relatively low cost and high throughput. Also, by using additional laser pulses (the "probe") to measure the response of the sample, very high time resolution can be achieved. The latter in particular is desirable when studying, for example shock waves, in which the time for the material to pass from undisturbed to fully compressed (the "rise time") can be extremely short (order 10 ps or less) even at fairly small peaks stresses. Since much of the most interesting physics comes into play during this process it is important to be able to adequately resolve the shock rise. Furthermore, the associated time scale is comparable to that typically considered in state-of-the-art molecular dynamics simulations which are emerging as the theoretical tool of choice for investigating shock waves in condensed matter. It should be pointed out however, that a general drawback to these techniques is that, depending on the aim of the experiment, a small pump energy imposes limits on the nature of the sample; if for example the aim is to study steady shock waves, the compressed region has to be thin, and its internal structure cannot vary on a scale that is not much smaller than the compressed dimensions. We consider and illustrate these concepts in the context of various metals, primarily aluminum and iron, and show how current methods are capable of making meaningful and useful measurements of material behavior at ultrahigh strain rates up to or exceeding 10^{10} s^{-1}, corresponding to more than 40 GPa in aluminum. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344 with Laboratory directed Research and Development funding (12ERD042), as well as being based on work supported as part of the EFree, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award No. DESC0001057.

11:51AM B24.00002 Orientation-dependent structure of elastic and plastic shock waves in Nickel single crystals , BRIAN DEMASKE, VASILY ZHAKHOVSKY, University of South Florida, NAIL INOGAMOV, Landau Institute for Theoretical Physics, IVAN OLEYNIK, University of South Florida — The response of Ni single crystals to shock loading has been investigated using molecular dynamics (MD) simulations. It was found that within the elastic-plastic split-shock-wave regime, the amplitude of the elastic precursor in the [111] direction depends strongly on the pressure of the plastic wave; whereas in the [110] direction the pressure of the elastic precursor is pinned. Coupling of the elastic and plastic waves in the [111] direction and lack thereof in the [110] direction is attributed to different activation mechanisms for homogeneous dislocation nucleation (HDN), the major relaxation process observed in our MD simulations. In the [111] direction, thermodynamic fluctuations activate HDN randomly within a metastable elastic zone separating the elastic and plastic fronts, while in the [110] direction HDN is induced by the high levels of shear stresses produced at the plastic front. We will discuss how thermally-activated HDN gives rise to a new pulsating regime of single two-zone elastic-plastic shock waves, where the elastic zone width undergoes significant oscillations in time.

12:03PM B24.00003 Atomistic simulations of high strain rate loading of nanocrystals[1] , E.M. BRINGA, D. TRAMONTINA, C.J. RUESTES, Instituto de Ciencias Basicas, Universidad Nacional de Cuyo, Y. TANG, M.A. MEYERS, University of California, San Diego, N. GUNKELMANN, H.M. URBASSEK, Physics Department and Research Center OPTIMAS, University Kaiserslautern, Germany — Materials loaded at high strain rates can reach extreme temperature and pressure conditions. Most experiments on loading of simple materials use poly crystals, while most atomistic simulations of shock wave loading deal with single crystals, due to the higher computational cost of running polycrystal samples. Of course, atomistic simulations of polycrystals with micron-sized grains are beyond the capabilities of current supercomputers. On the other hand, nanocrystals (nc) with grain sizes below 50 nm can be obtained experimentally and modeled reasonably well at high strain rates, opening the possibility of nearly direct comparison between atomistic molecular dynamics (MD) simulations and experiments using high power lasers. We will discuss MD simulations and links to experiments for nc Cu and Ni, as model f.c.c. solids, and nc Ta and Fe, as model b.c.c. solids. In all cases, the microstructure resulting from loading depends strongly on grain size, strain rate and peak applied pressure. We will also discuss effects related to target porosity in nc's.

[1]E.M.B. thanks funding from PICT2008-1325.

12:15PM B24.00004 Rarefaction shock waves in shock-compressed diamond <110> crystal , ROMAIN PERRIOT, YOU LIN, VASILY ZHAKHOVSKY, University of South Florida, CARTER WHITE, Naval Research Laboratory, IVAN OLEYNIK, University of South Florida — Piston-driven shock compression of diamond <110> crystal was simulated by molecular dynamics using the REBO potential. At piston velocities between 2 and 5 km/s and corresponding pressures 117 GPA $<$ P $<$ 278 GPa, diamond sample undergoes a polymorphic phase transition, characterized by the coexistence of two elastically compressed phases, low-pressure phase A and high-pressure phase B. This phase transition results in the splitting of the shock wave into two elastic shock waves, composed of pure phase A and a mixture of phases A and B. Upon removal of the piston, a release wave is observed at the rear of the sample, turning into a rarefaction shock wave where the material undergoes the reverse phase transition from coexisting phases to the original low-pressure phase. For strong plastic waves induced by larger piston velocities the release wave propagates as a rarefaction wave without any phase transition corresponding to the adiabatic expansion along the plastic branch of the Hugoniot.

12:27PM B24.00005 Efficient semiclassical quantum nuclear effects for shock compression studies , EVAN REED, Department of Materials Science and Engineering, Stanford University — A fast methodology is described for atomistic simulations of shock-compressed materials that incorporates quantum nuclear effects in a self-consistent fashion. We introduce a modification of the multiscale shock technique (MSST) that couples to a quantum thermal bath described by a colored noise Langevin thermostat. The new approach, which we call QB-MSST, is of comparable computational cost to MSST and self-consistently incorporates quantum heat capacities and Bose-Einstein harmonic vibrational distributions. As a first test, we study shock-compressed methane using the ReaxFF potential. The Hugoniot curves predicted from the new approach are found comparable with existing experimental data. We find that the self-consistent nature of the method results in the onset of chemistry at 40% lower pressure on the shock Hugoniot than observed with classical molecular dynamics. The temperature shift associated with quantum heat capacity is determined to be the primary factor in this shift.

In collaboration with Tingting Qi, Department of Materials Science and Engineering, Stanford University.

1:03PM B24.00006 Study of Plastic flow at high pressures and strain rates via the Rayleigh-Taylor instability[1] , HYE-SOOK PARK, J. BELOF, K. BLOBAUM, R. CAVALLO, B. MADDOX, C. PLECHATY, S. PRISBREY, B. REMINGTON, R. RUDD, C. WEHRENBERG, M. WILSON, LLNL — We present the results from study of tantalum material strength at high pressures and high strain rates using the Omega laser system. The Ta sample is maintained in the solid state via a quasi-isentropic ramped drive using a reservoir-gap-sample configuration at high pressures ($>$ 1 Mbar) and high strain rates (10^6 - 10^8 sec^{-1}). The strength is inferred by measurement of Rayleigh-Taylor induced growth in pre-imposed sinusoidal ripples on a Ta sample [1]. Our study of the samples with single crystal, 0.25, 15 and 90 micron average grain sizes shows that there is no obvious Hall-Petch effect under such extreme conditions. We also show that RT growth is linear as long as the RT growth is below 0.15 of the original sample thickness. We show a comparison of experimental results with the recently developed Livermore Multiscale model that integrates the atomistic scale physics to macro hydro flow simulations. The NIF experimental design will also be presented

1:15PM B24.00007 Dynamic diffraction measurements of Ta lattice response under Mbar shock loading conditions[1] , BRUCE REMINGTON, LLNL — We will report on experiments done on the Omega laser to determine the strength of shock-loaded single-crystal [100] tantalum using in-situ broadband x-ray Laue diffraction. The inferred strength reaches 350 kbar at a shock pressure of 1.8 Mbar and is in excellent agreement with a multiscale strength model, which employs a hierarchy of simulation methods over a range of length and time scales. Laser driven shock experiments using in situ Bragg diffraction were also performed at the Omega-EP laser on single crystal tantalum to study the dynamic yield strength and lattice dynamics. Both techniques will be described, comparisons to the strength models made, and interpretations of the results given. Recent results from recovery experiments in shocked single crystal Ta will also be given, showing features such as the residual dislocation density and slip-twinning threshold.

[1]This work was performed under the auspices of the Lawrence Livermore National Security, LLC, (LLNS) under Contract No. DE-AC52-07NA27344.

1:27PM B24.00008 Mesoscale Modeling of Shock Wave Propagation and Dynamic Failure in Metallic Systems , AVINASH DONGARE, Chemical, Materials & Biomolecular Engineering, University of Connecticut — The response of materials under conditions of thermomechanical extremes is very complex and involves damage creation and propagation, phase transformation, heat generation and transfer, etc. A principal challenge in predictive modeling of failure behavior is presented by the gap between the atomistic description of micromechanisms of the relevant processes and the macoscale response in continuum simulations/experiments. This difficulty can be approached through the development of a robust mesoscopic computational model that retains the relevant physics and is capable of representing the material behavior at time- and length-scales intermediate between the atomistic or continuum levels. Mesoscale models typically reduce a group of atoms by a mesoparticle system with much smaller number of collective degrees of freedom, and hence are often difficult to apply for problems such as heat transfer, phase transformation, and dissipation of mechanical energy during wave propagation. To achieve this goal, a novel mesoscopic model is being developed based on the idea of coarse-graining with the energetics defined for the particles based on interatomic potentials used in molecular dynamics (MD) simulations. The coarse-grained molecular dynamics simulations (CGMD) allows larger size systems and improved time-steps for simulations and thus able to extend the capabilities of MD simulations to model materials behavior at mesoscales. The successful application of the CGMD method is demonstrated by prediction of the phase-transformation, heat generation and wave-propagation behavior under the conditions of shock loading, as would be predicted using MD simulations.

1:39PM B24.00009 Microstructure in the Extreme Environment: Understanding and Predicting Dynamic Damage Processes , DARCIE DENNIS-KOLLER, ELLEN CERRETA, CURT BRONKHORST, PABLO ESCOBEDO-DIAZ, RICARDO LEBENSOHN, Los Alamos National Laboratory — The future of materials science: strategic application for functionally controlled materials properties is emphasized by the need to control material performance in extreme environments. This study examines the separate effects of kinetics (in the form of dynamic loading rate and shock wave shape) from that of length-scale effects (in the form of microstructural defect distributions). Recently available mesoscale modeling techniques are being used to capture a physical link between kinetic and length-scale influences on dynamic loading. This work contributes innovative new tools in the form of shock-wave shaping techniques in dynamic experimentation, materials characterization, lending insight into 3D damage field analysis at micron resolution, and the physics necessary to provide predictive capabilities for dynamic damage evolution. Experimental are obtained to provide the basis for the development of process-aware material performance models.

1:51PM B24.00010 Kinetics of a Fast Moving Partial Dislocation[1] , NITIN DAPHALAPURKAR[2], K.T. RAMESH, Johns Hopkins University — Plastic deformation in materials under extreme stresses requires a kinetic description of moving dislocations. The velocities with which the partial dislocations can propagate under an applied stress has implications for plasticity at high strain rates, specifically, the rate of plastic deformation and the rate-sensitivity. In this work, we focus our attention on motion of a twinning partial dislocation in a face-centered cubic (FCC) material, Ni. We use molecular dynamics simulations to simulate the velocity of a propagating twinning partial dislocation and investigate the effect of applied shear stress. Results suggest a limiting value for the speeds of a propagating partial dislocation. The material speeds based on the nonlinear part (under high stresses) of the stress-strain curve are shown to have an influence on the velocity with which a partial dislocation can propagate. Predicted velocities from simulations will be related to observations from high rate impact experiments.

2:03PM B24.00011 Characterization of several martensitic phase transitions under extreme conditions[1] , MANLING SUI, Institute of Microstructure and Property of Advanced Materials, Beijing University of Technology, Beijing, 100124, China, SHUJUAN WANG, WEI ZHANG, PENGFEI YAN, Shenyang National Laboratory for Materials Science, Institute of Metal Research, Chinese Academy of Sciences, Shenyang 110016, China — In shock-compressed α-iron, transmission electron microscopy (TEM) investigations revealed a refined microstructure with tale-telling features that are indicative of $\alpha \rightarrow \varepsilon \rightarrow \alpha$ sequential martensitic transformations, even though no ε phase was retained. The unique microstructural fingerprints enable a quantitative assessment of the volume fraction transformed during explosive loading. In a Ti–6Al–4V alloy, an unusual martensitic transformation from α-Ti to β-Ti occurred by a high-density current pulse, instead of the conventional martensitic transformation from β-Ti to α-Ti. A large amount of the high-temperature phase remained. By pulsed laser irradiation, a solid-state phase transition from the α to the γ phase of aluminum oxide was observed for the first time. High resolution TEM reveals that the transformation is achieved via the glide of quarter partial dislocations on every other basal plane of α-Al_2O_3. This martensitic transformation is associated with a positive volume change and substantial shear strain.

Session B25 GQI: Superconducting Qubits: Loss Mechanisms (TLS) and Novel Materials 327

- David Pappas, National Institute of Standards and Technology

11:15AM B25.00001 Delocalised oxygen as the origin of two-level defects in Josephson junctions , JARED COLE, TIMOTHY DUBOIS, Chemical and Quantum Physics, School of Applied Sciences, RMIT University, Melbourne 3001, Australia, MANOLO PER, Virtual Nanoscience Laboratory, CSIRO Materials Science and Engineering, Parkville 3052, Australia, SALVY RUSSO, Chemical and Quantum Physics, School of Applied Sciences, RMIT University, Melbourne 3001, Australia — One of the key problems facing superconducting qubits and other Josephson junction devices is the decohering effects of bi-stable material defects. Although a variety of phenomenological models exist, the true microscopic origin of these defects remains elusive. We show that these defects can arise from delocalisation of the atomic position of the oxygen in the oxide forming the Josephson junction barrier. Using a microscopic model, we compute experimentally observable parameters for phase qubits. Such defects are charge neutral but have non-zero response to both applied electric field and strain. This explains the observed long coherence time of two-level defects in the presence of charge noise, while still coupling to the junction electric field and substrate phonons.

11:27AM B25.00002 Noise from Two-Level Systems in Superconducting Resonators , C. NEILL, R. BARENDS, Y. CHEN, B. CHIARO, E. JEFFREY, J. KELLY, M. MARIANTONI, A. MEGRANT, J. MUTUS, S. OHYA, D. SANK, A. VAINSENCHER, J. WENNER, T. WHITE, A. N. CLELAND, J. M. MARTINIS, UC Santa Barbara — Two-level systems (TLSs) present in amorphous dielectrics and surface interfaces are a significant source of decoherence in superconducting qubits. Linear microwave resonators offer a valuable instrument for characterizing the strongly power-dependent response of these TLSs. Using quarter-wavelength coplanar waveguide resonators, we monitored the microwave response of the resonator at a single near-resonant frequency versus time at varying microwave drive powers. We observe a time dependent variation of the resonator's internal dissipation and resonance frequency. The amplitude of these variations saturates with power in a manner similar to loss from TLSs. These results provide a means for quantifying the number and distribution of TLSs.

11:39AM B25.00003 Universal dielectric loss in amorphous solids in Josephson qubits from simultaneous bias and microwave fields , ALEXANDER BURIN, Tulane University, KEVIN OSBORN, LPS University of Maryland, KHALIL MOE, LPS, University of Maryland — We calculate the microwave dielectric loss of an ensemble of two-level systems in amorphous solids within superconducting qubits during the application of a time-varying electric bias field. We find that this loss becomes universal in a wide range of temperatures and frequencies of the AC drive field, corresponding to the bare linear dielectric permittivity in the low-temperature limit. This non-equilibrium theory allows the separate extraction of the TLS density and their dipole size in experiments and can be used to reduce the destructive effect of decoherence.

11:51AM B25.00004 Polaronic model of Two Level Systems in amorphous solids , KARTIEK AGARWAL, Harvard University, IVAR MARTIN, Los Alamos National Laboratory, EUGENE DEMLER, MIKHAIL LUKIN, Harvard University — Motivated by recent experiments studying effects of elastic strain on two level systems (TLSs) in Josephson Junctions, we consider interaction of the electronic TLS with phonons. We demonstrate that including strong polaronic effects is crucial for analyzing these systems. Our model not only gives a quantitative understanding of the TLS relaxation and dephasing as probed in Josephson junction qubits, but also provides a microscopic justification for phenomenological models used to describe experiments with bulk amorphous solids. Our model explains such surprising observations of recent experiments as the existence of minima in the energy of some TLSs as a function of strain and maximum of the relaxation time in such minima. We argue that better understanding of the microscopic nature of TLSs can be used to improve properties of quantum devices, from dramatic enhancement of TLS relaxation time by putting them inside phononic crystals to creating new types of strongly interacting optomechanical systems.

12:03PM B25.00005 Superconducting Titanium Nitride Coplanar Resonators: Relationships between performance and deposition parameters[1] , B. CHIARO, S. OHYA, A. MEGRANT, C. NEILL, R. BARENDS, B. CAMPBELL, Y. CHEN, J. KELLY, M. MARIANTONI, J. MUTUS, P. O'MALLEY, P. ROUSHAN, D. SANK, A. VAINSENCHER, J. WENNER, T. WHITE, C.J. PALMSTROM, B.A. MAZIN, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — Superconducting coplanar waveguide (CPW) resonators are widely used structures in the fields of photon detection and quantum information processing. Recently, there has been a growing interest in titanium nitride (TiN) thin films due to their widely tunable critical temperature, large surface inductance, and ability to produce high intrinsic quality factor (Q_i) resonators. We have deposited nearly stoichiometric TiN films on Si substrates by reactive magnetron sputtering. By increasing the deposition pressure and adjusting the N2 flow rate to maintain stoichiometry, the film stress was changed from ~ 100 MPa to > 3000 MPa and the Q_i of CPW resonators made from these films increased from $\sim 10^4$ to $\sim 10^6$ for single photon excitations measured at ~ 100 mK. In this talk, we discuss relationships between deposition parameters, film properties, and microwave electrodynamic responses in these resonators.

12:15PM B25.00006 Characterization of quantum-regime dielectric loss of aluminum oxide using superconducting LC resonators , CHUNQING DENG, MARTIN OTTO, ADRIAN LUPASCU, University of Waterloo — We report low-temperature measurements of dielectric loss of thin layers of aluminum oxide. The experiments are performed by measuring the microwave transmission of coplanar waveguides coupled to LC resonators where the capacitor contains the dielectric to be characterized. We develop a method, based on systematic approximations of transfer functions, to analyze the measured transmission curves. The fit of the resonance curves yields not only the loss tangent of the dielectric, but also the relation between the voltage on the capacitor and the excitation voltage. The latter is a nonlinear relation which has to be properly taken into account when analyzing the power dependence of dielectric loss. We find that the loss tangent of the aluminum oxide increases with decreasing capacitor voltage and temperature and reaches a constant value around 2×10^{-3} at sub-single photon levels. Our results are qualitatively in agreement with the two-level system defect model. Despite large loss, compact resonators based on these dielectrics have potential applications in microwave amplifiers. These results are relevant to understanding decoherence in superconducting quantum devices.

12:27PM B25.00007 ABSTRACT WITHDRAWN –

12:39PM B25.00008 Observation of Cavity QED in thick dielectric films , BAHMAN SARABI, Laboratory for Physical Sciences, University of Maryland - College Park, A.N. RAMANAYAKA, S. GLADCHENKO, M.J.A. STOUTIMORE, Laboratory for Physical Sciences, M.S. KHALIL, Laboratory for Physical Sciences, University of Maryland - College Park, K.D. OSBORN, Laboratory for Physical Sciences — Cavity QED in amorphous dielectrics is investigated by measuring five linear superconducting resonators with thick dielectric films and capacitor volumes ranging from $80\mu m^3$ to $5000\mu m^3$. In the smallest volume dielectrics we observe additional resonances which may be explained by CQED, despite the dielectric volume which is many orders of magnitude larger than Josephson junction barrier volumes. In addition to the volume dependence of the CQED resonances, we will report on the stability of the resonances in time and the phase noise. This research allows new fundamental studies on TLS phenomena in meso-volume amorphous dielectrics.

12:51PM B25.00009 TLS-like temperature and power dependence for loss in superconducting coplanar resonators , S. GLADCHENKO, M.J.A. STOUTIMORE, M. KHALIL, K. D. OSBORN, Laboratory for Physical Sciences, MD, USA — Loss in 2D superconducting coplanar resonators and qubits is often limited by two-level systems thought to be on the metal and substrate surfaces. While these TLSs are thought to be similar to those found in amorphous dielectrics, their nature is generally different. In most experiments, loss in coplanar resonators shows power and temperature dependence which disagrees with TLS theory. Here we will show new data from high-quality Al on sapphire coplanar resonators which is in qualitative agreement with TLS theory, and discuss the quantitative differences to TLS theory. The data on surface TLS behavior will be compared to resonator measurements of ALD-grown thin films.

1:03PM B25.00010 Non-equilibrium two-level system dynamics probed with a biased bridge resonator , MOE S. KHALIL, SERGIY GLADCHENKO, M.J.A. STOUTIMORE, University of Maryland and Laboratory for Physical Sciences, F.C. WELLSTOOD, University of Maryland, K.D. OSBORN, Laboratory for Physical Sciences — We have designed a biased bridge resonator (BBR), which allows us to probe amorphous dielectric films by simultaneously applying a quasi-static electric bias field in addition to a microwave electric field. The BBR is made with a bridge arrangement of capacitors using superconducting aluminum electrodes and operated at millikelvin temperatures. Measurements of a universal amorphous dielectric film at high microwave amplitudes and a sufficiently fast bias field ramp reveals a non-equilibrium dielectric loss equal to its intrinsic steady state value. This phenomenon is explained by a theory which uses the dynamics of charged two-level systems undergoing Landau-Zener transitions to remain in their ground state. We will compare the experimental data to Monte Carlo simulations of the theory which allow for the separate extraction of the dipole moment and the spectral density of two-level systems.

1:15PM B25.00011 Observation of the dynamics of two-state parametric fluctuators in superconducting flux qubits[1] , ADRIAN LUPASCU, MUSTAFA BAL, MOHAMMAD ANSARI, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo — Spectroscopic measurements of a few persistent current qubit samples yield data in which the spectroscopic lines are doublets. The doublet splitting decreases with increasing qubit transition frequency. In three devices with a relatively low Josephson to charging energy ratio E_J/E_c, the maximum splitting ranges between 30 and 270 MHz. The splitting value is found to have variations over time scales of the order of days. The doublet structure was not observed in two other samples with larger E_J/E_c. Assuming a model in which the qubit experiences a parametric fluctuation that changes its frequency, we perform an experiment to probe the time scale of this fluctuation. We repeat a sequence in which the qubit is reset by energy relaxation, then driven with weak Rabi π pulses on one of the spectroscopy lines, and finally measured. The time correlation of the series of measurement results displays an exponential decay, consistent with a telegraph noise component in the qubit frequency. The correlation does not depend on time if the qubit is either not excited or driven with a strong Rabi pulse. The transition rate was found to vary between 8 kHz and 38 kHz for temperatures between 43 and 165 mK. We discuss quasiparticle poisoning and other possible source of this effect.

1:27PM B25.00012 Low-frequency two level systems and $1/f$ noise in Al/AlO$_x$/Al Josephson junctions for superconducting qubits: achieving a noiseless junction[1] , CHRISTOPHER NUGROHO, VLADIMIR ORLYANCHIK, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — The characterization of low-frequency two level systems (TLS) provides a connection between the generic $1/f$ noise in Josephson junctions to the TLSs observed in qubit energy spectroscopy. We present measurements of the tunneling-resistance noise in nanoscale Al/AlO$_x$/Al shadow evaporated junctions with areas $< (100\ \mathrm{nm})^2$. As the junction area or the temperature is decreased we observed a crossover from ensemble-averaged $1/f$ noise to a random telegraph noise from isolated TLSs. From the area threshold for the onset of non-gaussianity, we estimate a density of TLSs in the amorphous AlO$_x$ barrier consistent with the magnitude of $1/f$ noise in larger junctions and the density of high frequency TLSs from qubit spectroscopy. Furthermore we may deduce the potential landscape of the TLSs by characterizing the switching times and signal variance as a function of voltage bias and temperature. In some junctions no fluctuators are active, giving rise to immeasurably small noise signal. We discuss the implication of our findings to qubit coherence times.

1:39PM B25.00013 Josephson Phase Qubits Incorporating Novel Coherent Materials , U. PATEL, Y. GAO, D. HOVER, G. RIBEILL, S. SENDELBACH, R. MCDERMOTT, University of Wisconsin, Madison — The Josephson phase qubit is an attractive candidate for scalable quantum information processing in the solid state; however, qubit coherence is currently limited by coupling to spurious microscopic defects in the materials used to realize the circuit. Here we demonstrate that the incorporation of crystalline, defect-free dielectrics into the circuit leads to a dramatic enhancement of energy relaxation times. In addition we describe the realization of improved superconductor-insulator interfaces with extremely low levels of excess low-frequency flux noise, and we discuss efforts to incorporate these interfaces into the qubit circuit in order to extend pure dephasing times. We describe qubit fabrication and tomographic characterization and discuss ultimate limits to qubit coherence.

1:51PM B25.00014 Optimization of Transmon Qubit Fabrication[1] , JOSEPHINE CHANG, MARY BETH ROTHWELL, GEORGE KEEFE, IBM T.J. Watson Research Center, IBM QUANTUM COMPUTING GROUP TEAM — Rapid advances in the field of superconducting transmon qubits have refined our understanding of the role that substrate and interfaces play in qubit decoherence. Here, we review strategies for enhancing coherence times in both 2D and 3D transmon qubits through substrate design, structural improvements, and process optimization. Results correlating processing techniques to decoherence times are presented, and some novel structures are proposed for further consideration.

Session B26 GQI: Focus Session: Quantum Characterization, Verification, and Validation I 328 - Charles Tahan, Laboratory for Physical Sciences

11:15AM B26.00001 Using Compressed Sensing for Quantum Tomography , STEVE FLAMMIA, University of WashingtonSydney — No abstract available.

11:51AM B26.00002 Analyzing quantum simulators efficiently: Scalable state tomography and quantifying entanglement with routine measurements , MARCUS CRAMER, TILLMANN BAUMGRATZ, OLIVER MARTY, Ulm University, DAVID GROSS, Freiburg University, MARTIN PLENIO, Ulm University — Conventional full state tomography reaches its limit already for a few qubits and hence novel methods for the verification and benchmarking of quantum devices are called for. We show how the complete reconstruction of density matrices is possible even if one relies only on local information about the state. This results in an experimental effort that is linear in the number of qubits and efficient post-processing – in stark contrast to the exponential scaling of standard tomography. Whenever full tomography is not needed but instead less information required, one would expect that even fewer measurements suffice. Taking entanglement content of solid state samples and bosons in lattices as an example, we show how it may be quantified unconditionally using already routinely performed measurements only.

12:03PM B26.00003 Quantum Estimation, meet Computational Statistics; Computational Statistics, meet Quantum Estimation , CHRIS FERRIE, Center for Quantum Information and Control and Department of Physics and Astronomy, University of New Mexico, CHRIS GRANADE, Institute for Quantum Computing and Department of Physics and Astronomy, University of Waterloo, JOSHUA COMBES, Center for Quantum Information and Control and Department of Physics and Astronomy, University of New Mexico — Quantum estimation, that is, post processing data to obtain classical descriptions of quantum states and processes, is an intractable problem—scaling exponentially with the number of interacting systems. Thankfully there is an entire field, Computational Statistics, devoted to designing algorithms to estimate probabilities for seemingly intractable problems. So, why not look to the most advanced machine learning algorithms for quantum estimation tasks? We did. I'll describe how we adapted and combined machine learning methodologies to obtain an online learning algorithm designed to estimate quantum states and processes.

12:15PM B26.00004 Direct characterization of any linear photonic device , ALESSANDRO FEDRIZZI, MATTHEW BROOME, ANDREW WHITE, ARC Centre for Engineered Quantum Systems, School of Mathematics and Physics, University of Queensland, Brisbane, Australia, ROBERT FICKLER, University of Vienna, Boltzmanngasse 5, Vienna, A-1090 Austria, SALEH RAHIMI-KESHARI, TIMOTHY RALPH, ARC Centre for Quantum Computer and Communication Technology, School of Mathematics and Physics, University of Queensland, Brisbane, Australia — Linear photonic devices comprised of simple beamsplitters and phase shifters can implement any unitary operator for quantum information processing. The significant practical challenge is to characterize such an interferometric device once it is built. Performing quantum process tomography requires the full suite of quantum tools such as N-mode quantum state preparation and measurement, and is, despite progress on more efficient methods, slow and impractical for large interferometric devices. Here we introduce a simple technique to characterize the unitary matrix of a linear photonic device using standard laser sources and photodetectors, without the requirement for active locking or single-photon sources. Our method is precise and efficient, requiring only 2N-1 measurement configurations for a N-path network. We use it experimentally to characterise an integrated 3x3 fused-fibre coupler and highlight its precision by comparing measured quantum interference patterns with those predicted using the classically-estimated unitary. We observe excellent agreement between the two experimental methods.

12:27PM B26.00005 Ultrafast Quantum Process Tomography via Continuous Measurement and Convex Optimization[1] , CHARLES BALDWIN, CQuIC University of New Mexico, CARLOS RIOFRIO, Free University of Berlin, IVAN DEUTSCH, CQuIC University of New Mexico — Quantum process tomography (QPT) is an essential tool to diagnose the implementation of a dynamical map. However, the standard protocol is extremely resource intensive. For a Hilbert space of dimension d, it requires d^2 different input preparations followed by state tomography via the estimation of the expectation values of d^2-1 orthogonal observables. We show that when the process is nearly unitary, we can dramatically improve the efficiency and robustness of QPT through a collective continuous measurement protocol on an ensemble of identically prepared systems. Given the measurement history we obtain the process matrix via a convex program that optimizes a desired cost function. We study two estimators: least-squares and compressive sensing. Both allow rapid QPT due to the condition of complete positivity of the map; this is a powerful constraint to force the process to be physical and consistent with the data. We apply the method to a real experimental implementation, where optimal control is used to perform a unitary map on a $d=8$ dimensional system of hyperfine levels in cesium atoms, and obtain the measurement record via Faraday spectroscopy of a laser probe.

12:39PM B26.00006 Finding systematic errors in tomographic data: Characterising ion-trap quantum computers , THOMAS MONZ, University of Innsbruck — Quantum state tomography has become a standard tool in quantum information processing to extract information about an unknown state. Several recipes exist to post-process the data and obtain a density matrix; for instance using maximum-likelihood estimation. These evaluations, and all conclusions taken from the density matrices, however, rely on valid data - meaning data that agrees both with the measurement model and a quantum model within statistical uncertainties. Given the wide span of possible discrepancies between laboratory and theory model, data ought to be tested for its validity prior to any subsequent evaluation. The presented talk will provide an overview of such tests which are easily implemented. These will then be applied onto tomographic data from an ion-trap quantum computer.

1:15PM B26.00007 Adaptive quantum gate-set tomography[1] , ROBIN BLUME-KOHOUT, Sandia National Laboratories — Quantum information hardware needs to be characterized and calibrated. This is the job of quantum state and process tomography, but standard tomographic methods have an Achilles heel: to characterize an unknown process, they rely on a set of absolutely calibrated measurements. But many technologies (e.g., solid-state qubits) admit only a single native measurement basis, and other bases are measured using unitary control. So tomography becomes circular – tomographic protocols are using gates to calibrate themselves! Gate-set tomography confronts this problem head-on and resolves it by treating gates relationally. We abandon all assumptions about what a given gate operation does, and characterize entire universal gate sets from the ground up using only the observed statistics of an [unknown] 2-outcome measurement after various strings of [unknown] gate operations. The accuracy and reliability of the resulting estimate depends critically on which gate strings are used, and benefits greatly from adaptivity.

[1]Sandia National Labs is a multiprogram laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Dept. of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000

1:27PM B26.00008 Quadratically faster state tomography using single-step adaptation , DYLAN MAHLER, LEE ROZEMA, ARDAVAN DARABI, Centre for Quantum Information & Quantum Control and Institute for Optical Sciences, Dept. of Physics, 60 St. George St., University of Toronto, CHRISTOPHER FERRIE, Institute for Quantum Computing and Department of Applied Mathematics, University of Waterloo, ROBIN BLUME-KOHOUT, Sandia National Laboratories, AEPHRAIM STEINBERG, Centre for Quantum Information & Quantum Control and Institute for Optical Sciences, Dept. of Physics, 60 St. George St., University of Toronto — In quantum state tomography, an informationally complete set of measurements is made on N identically prepared quantum systems and from these measurements the quantum state can be determined. In the limit as $N \to \infty$ the estimate of the state converges on the true state. The rate at which this convergence occurs depends on both the state and the measurements used to probe the state. On the one hand, since nothing is known a priori about the state being probed, a set of maximally unbiased measurements should be made. On the other hand, if something was known about the state being measured a set of biased measurements would yield a more accurate estimate. It has been shown[1,2] that by adaptively choosing measurements optimal accuracy in the state estimate can be obtained regardless of the state being measured. Here we present an experimental demonstration of one-qubit adaptive tomography that achieves a rate of convergence of $1-O(\frac{1}{N})$ in the quantum state fidelity with only a single adaptive step and local measurements, as compared to $1-O(\frac{1}{\sqrt{(N)}})$ for standard tomography. Furthermore, we show how this protocol generalizes to arbitrarily entangled two-qubit systems. [1] Phys. Rev. Lett. 97, 130501 (2006) [2] Phys. Rev. A 85, 052120 (2012)

1:39PM B26.00009 Quantum process tomography of energy and phase relaxation through adaptive measurements[1] , MARKKU STENBERG, FRANK WILHELM[2], Saarland University — Quantum process tomography tends to be very time consuming when multiple degrees of freedom are studied simultaneously. We propose a method of efficient quantum process tomography to estimate the energy and phase relaxation rates in qubits. The method applies Bayesian inference to adaptively choose measurements based on the previously obtained measurement outcomes. We adopt sequential Monte-Carlo approach to perform the Bayesian updates and make use of a fast numerical implementation of the algorithm. We compare the performance of our method to conventional offline (implemented after experimental data collection) strategies and illustrate how our method can speed up quantum process tomography.

1:51PM B26.00010 A quantum neural network computes its own relative phase , ELIZABETH BEHRMAN, Mathematics and Physics, Wichita State University, Wichita, KS 67260-0033 — Complete characterization of the state of a quantum system made up of subsystems requires determination of relative phase, because of interference effects between the subsystems. For a system of qubits used as a quantum computer this is especially vital, because the entanglement, which is the basis for the quantum advantage in computing, depends intricately on phase. We present here a first step towards that determination, in which we use a two-qubit quantum system as a quantum neural network, which is trained to compute and output its own relative phase.

2:03PM B26.00011 Modeling quantum noise for efficient testing of fault-tolerant circuits , EASWAR MAGESAN, Massachusetts Institute of Technology, DANIEL PUZZUOLI, CHRISTOPHER E. GRANADE, DAVID G. CORY, University of Waterloo-Institute for Quantum Computing — Simulating fault-tolerant properties of quantum circuits is important for the design of large-scale quantum information processors. For general circuits and noise models, these simulations quickly become intractable in the size of the encoded circuit. We introduce methods for approximating a noise process by one which allows for efficient Monte Carlo simulation of properties of encoded circuits. The approximations are as close to the original process as possible without overestimating their ability to preserve quantum information, a key property for obtaining more honest estimates of threshold values. We numerically illustrate the method with physically relevant noise models.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B27 GQI: Focus Session: Adiabatic Quantum Computing II 329 - Sergio Boixo, University of Southern California

11:15AM B27.00001 On optimal methods for adiabatic quantum state transformations[1] , ROLANDO SOMMA, Los Alamos National Laboratory — Many problems in science could be solved by preparing the low-energy quantum state (or any eigenstate) of a Hamiltonian. A common example is the Boolean satisfiability problem, where each clause can be mapped to the energy of an interacting many-body system, and the problem reduces to minimizing the energy. In quantum computing, adiabatic quantum state transformations (ASTs) provide a tool for preparing the quantum state. ASTs are conventionally implemented via slow or adiabatic perturbations to the Hamiltonian, relying on the quantum adiabatic theorem. Nevertheless, more efficient implementations of ASTs exist. In this talk I will review recently developed methods for ASTs that are more efficient and require less assumptions on the Hamiltonians than the conventional implementation [1,2]. Such methods involve measurements of the states along the evolution path and have a best-case implementation cost of L/G, where L is the length of the (evolved) state path and G is a lower bound to the spectral gap of the Hamiltonians. I will show that this cost is optimal [3] and comment on results of the gap amplification problem, where the goal is to reduce the cost by increasing G [4].

11:51AM B27.00002 Quantum Adiabatic Markovian Master Equations , TAMEEM ALBASH, SERGIO BOIXO, DANIEL LIDAR, PAOLO ZANARDI, University of Southern California — We develop from first principles Markovian master equations suited for studying the time evolution of a system evolving adiabatically while coupled weakly to a thermal bath. We derive two sets of equations in the adiabatic limit, one using the rotating wave approximation that results in a master equation in Lindblad form, the other without the rotating wave approximation but not in Lindblad form. We use our formalism to study the evolution of Ising spin Hamiltonians and compare to experimental results from the D-Wave One Rainier chip. In particular, we study an Ising Hamiltonian that gives markedly different predictions for the ground state spectrum when solved using classical thermal annealing versus quantum annealing, and our master equations give qualitatively consistent results with the results of the D-Wave chip.

12:03PM B27.00003 Quantum Simulation for Open-System Dynamics[1] , DONG-SHENG WANG, University of Calgary, MARCOS CESAR DE OLIVEIRA, University of Calgary, Universidade Estadual de Campinas, DOMINIC BERRY, Macquarie University, BARRY SANDERS, University of Calgary — Simulations are essential for predicting and explaining properties of physical and mathematical systems yet so far have been restricted to classical and closed quantum systems [1,2]. Although forays have been made into open-system quantum simulation [3], the strict algorithmic aspect has not been explored yet is necessary to account fully for resource consumption to deliver bounded-error answers to computational questions. An open-system quantum simulator would encompass classical and closed-system simulation and also solve outstanding problems concerning, e.g. dynamical phase transitions in non-equilibrium systems, establishing long-range order via dissipation, verifying the simulatability of open-system dynamics on a quantum Turing machine. We construct an efficient autonomous algorithm for designing an efficient quantum circuit to simulate many-body open-system dynamics described by a local Hamiltonian plus decoherence due to separate baths for each particle. The execution time and number of gates for the quantum simulator both scale polynomially with the system size.

12:15PM B27.00004 Complexity of the Quantum Adiabatic Algorithm , ITAY HEN, UC Santa Cruz and NASA Ames Research Center — The Quantum Adiabatic Algorithm (QAA) has been proposed as a mechanism for efficiently solving optimization problems on a quantum computer. Since adiabatic computation is analog in nature and does not require the design and use of quantum gates, it can be thought of as a simpler and perhaps more profound method for performing quantum computations that might also be easier to implement experimentally. While these features have generated substantial research in QAA, to date there is still a lack of solid evidence that the algorithm can outperform classical optimization algorihms. Here, we discuss several aspects of the quantum adiabatic algorithm: We analyze the efficiency of the algorithm on several "hard" (NP) computational problems. Studying the size dependence of the typical minimum energy gap of the Hamiltonians of these problems using quantum Monte Carlo methods, we find that while for most problems the minimum gap decreases exponentially with the size of the problem, indicating that the QAA is not more efficient than existing classical search algorithms, for other problems there is evidence to suggest that the gap may be polynomial near the phase transition. We also discuss applications of the QAA to "real life" problems and how they can be implemented on currently available (albeit prototypical) quantum hardware such as "D-Wave One", that impose serious restrictions as to which type of problems may be tested. Finally, we discuss different approaches to find improved implementations of the algorithm such as local adiabatic evolution, adaptive methods, local search in Hamiltonian space and others.

12:51PM B27.00005 Power law scaling for the adiabatic algorithm for search engine ranking[1] , ADAM FREES, Department of Physics, Brown University, Providence, RI 02912, JOHN KING GAMBLE, KENNETH RUDINGER, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706, ERIC BACH, Department of Computer Sciences, University of Wisconsin-Madison, Madison, WI 53706, MARK FRIESEN, ROBERT JOYNT, S. N. COPPERSMITH, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706 — An important method for search engine result ranking works by finding the principal eigenvector of the "Google matrix." Recently, a quantum algorithm for this problem and evidence of an exponential speedup for some scale-free networks were presented. Here, we show that the run-time depends on features of the graphs other than the degree distribution, and can be altered sufficiently to rule out a general exponential speedup. For a sample of graphs with degree distributions that more closely resemble the Web than in the previous work, the proposed algorithm does not appear to run exponentially faster than the classical one.

1:03PM B27.00006 Frustration and ground state entanglement in 2D lattices , ARTUR GARCIA, C. N. Yang Institute for Theoretical Physics, USA, JOSE I. LATORRE, Universitat de Barcelona, Spain — We investigate frustrated 2D lattice systems with an Ising-type interaction using exact diagonalization and Tensor Network techniques. The geometric frustration in these systems is controlled by the couplings of the Hamiltonian. We study the ground state entanglement for the combination of model parameters inducing a higher degree of frustrated interactions, showing relations between the frustration and the amount of quantum correlations present along different partitions of the lattice. Using the connection between ground state entanglement and the classical simulation of quantum systems, these results point to scenarios where simulating local systems is supposed to be hard.

1:15PM B27.00007 Cycloid trajectory for a spin in a rotating magnetic field , SANGCHUL OH, XUEDONG HU, Department of Physics, University at Buffalo, The State University of New York — A cycloid is a curve traced by a point on the rim of a circle rolling on a straight (or in general, a base) line. In classical mechanics, it is known as the solution of two famous problems: the brachistochrone (least-time) curve and tautochrone (equal-time) curve. Here we show that a cycloid is the quantum trajectory on the Bloch sphere when a spin is dragged along by a rotating magnetic field. Here an imaginary circle, whose radius is determined by how fast the magnetic field is rotating, rolls on the base line of the rotating magnetic field on the Bloch sphere. If the magnetic field rotates slower, the radius of the rolling circle shrinks (to a point at the adiabatic limit, when the trajectory traces a circle that spans a solid angle proportional to the Berry phase). We find that like classical cycloid curves, the curtate cycloid on a Bloch sphere is generated for initial states within a circle on the Bloch sphere surface, and a prolate cycloid results from initial states outside of this circle. If the initial state is given by the center of the circle, the quantum trajectory is a line of a constant latitude on the Bloch sphere, parallel to the curve of the rotating magnetic field.

1:27PM B27.00008 Fibonacci wires , ALEXEY SOLUYANOV, MATTHIAS TROYER, ETH Zurich — We show that models for one-dimensional quantum chains with local interactions can exhibit non-Abelian end modes, going beyond Kitaev's Majorana chain. We describe a model for a special case of $\mathrm{SU}(2)_{\mathrm{k}}$ anyons, in particular Fibonacci anyons, and show how braiding of non-Abelian end modes can be done in networks of such chains.

1:39PM B27.00009 Dynamical scaling in infinitely correlated many-body systems through a quantum phase transition , OSCAR LEONARDO ACEVEDO, LUIS QUIROGA, FERNEY JAVIER RODRIGUEZ, Universidad de los Andes, Bogota, NEIL JOHNSON, University of Miami, Coral Gables, Miami, FL — We assess dynamical scaling of many two-level systems (TLSs) infinitely correlated, either through a mediating radiation mode as in the Dicke Model, or through a direct interaction between TLSs as in the Lipkin-Meshkov-Glick model. Those models are characterized by the presence of a Quantum Phase Transition (QPT) in the thermodynamic limit, and they belong to the same universality class. The assessment is done by means of exact computational simulations of finite-size systems under linear rampings of the interaction parameter crossing the quantum critical point. Our results exhibit significant differences with respect to previous works on dynamical scaling across QPTs in the near-adiabatic regime, which have focused on spin-chain models where correlation lengths can be defined. We have confirmed that in infinitely correlated models an effective system size can play the role of the correlation length in traditional scaling arguments. However, due to the infinite correlation among TLSs, the standard Kibble-Zurek mechanism is not realized as the system cannot fully enter an adiabatic evolution during the ordered phase. Also, in the two-level approximation, a suitable deviation from the standard Landau-Zener protocol must be performed in order to obtain scaling collapse.

1:51PM B27.00010 Phase transition detection using Renyi entropy in quantum and classical systems , STEPHEN INGLIS, JASON IACONIS, ANN KALLIN, ROGER MELKO, University of Waterloo — By extending the calculation of the Renyi entropy from quantum models [Phys. Rev. B 82, 100409(R) (2010)] to classical modes, we introduce a general procedure to calculate the Renyi mutual information in Monte Carlo simulations. Examining an array of quantum and classical models we show that the mutual information is able to detect general finite temperature phase transitions from different universality classes without knowledge of the specific order parameter or any special thermodynamic estimators. We demonstrate this technique on a standard symmetry breaking phase transition, the classical Ising model and anisotropic Heisenberg model, and a vortex-unbinding transition without a local order parameter, the classical and quantum XY model, and present the details necessary to implement this procedure on other models [arXiv:1210.2403].

Session B28 GSNP: Focus Session: Statistical Physics of Active Systems Away from Detailed Balance: Motors, Swimmers and All That 336 - Alexander Grosberg, New York University

11:15AM B28.00001 Mechanics and Stability of Healthy and Cancerous Tissues

, THOMAS RISLER, Institut Curie; UPMC Univ Paris 06; and CNRS, UMR 168, F-75005, Paris, France — We study the stability of the interface between a multilayered epithelium and its adjacent stroma. Treating the epithelium as a viscous fluid with cell division, we find a novel hydrodynamic instability that leads to the formation of fingering protrusions of the epithelium into the stroma [1]. Coupling cell division in the epithelium to the local concentration of nutrients diffusing from the stroma enhances the instability by a mechanism similar to that of the Mullins-Sekerka instability in single-diffusion processes of crystal growth [2]. This instability provides physical insight into a potential mechanism by which interfaces between epithelia and stroma undulate, and potentially by which tissue dysplasia leads to cancerous invasion. Later in the process of cancerous invasion, mechanics may also play an important part. We have recently proposed that one aspect of homeostasis is the regulation of tissues to preferred pressures, which can lead to a competition for space of purely mechanical origin and be an underlying mechanism for tumor growth. Surface and bulk contributions to growth lead to the existence of a critical size that must be overcome by metastases to nucleate macroscopic secondary tumors [3]. This property qualitatively explains the observed size distributions of metastases. Following these ideas, the influence of an externally applied osmotic stress on the long-term growth of cellular spheroids has been experimentally demonstrated [4].

In collaboration with M. Basan, F. Montel, M. Delarue, J. Elgeti, G. Cappello, J.-F. Joanny, Institut Curie, Centre de Recherche, UPMC Univ Paris 06, and CNRS, UMR 168, F-75005, Paris, France; and J. Prost, Institut Curie, Centre de Recherche, UPMC Univ Paris 06, CNRS, UMR 168, and 4ESPCI ParisTech, F-75005, Paris, France.

11:51AM B28.00002 In-silico studies of the collective motility of cells crawling on a thick elastic substrate[1]

, APARNA BASKARAN, ARVIND GOPINATH, MICHAEL HAGAN, Brandeis University — Self-propelling cells crawling on elastic substrates are an example of a collective system that is driven away from equilibrium. Experiments show that such cells communicate with their neighbors by sensing the deformation of the underlying elastic substrate. We propose a minimal, over-damped Brownian dynamics simulation to mimic and study this emergent collective motility. The simulations incorporate intrinsic activity at the single cell level due to self-propulsion, noise and inter-cell interactions via the underlying elastic substrate. Elastic interactions are modeled on a pair-wise additive basis by treating each cell as a force dipole deforming the substrate. We find that self-propulsion, combined with elastic interaction is sufficient to generate the coordinated large scale streaming, migration, jamming and swirling motions observed in experiments. We extract the length and time scales characterizing these correlated motions and thresh out their dependence on activity and elastic interactions. The results are rationalized by deriving a mean-field hydrodynamic theory and studying the linear stability of the equations. Our results provide a unified picture of the patterns of collective migration resulting from mechanical interactions without overlying chemical cues.

12:03PM B28.00003 Growth of Bacterial Colonies

, MYA WARREN, TERENCE HWA, University of California, San Diego — On hard agar gel, there is insufficient surface hydration for bacteria to swim or swarm. Instead, growth occurs in colonies of close-packed cells, which expand purely due to repulsive interactions: individual bacteria push each other out of the way through the force of their growth. In this way, bacterial colonies represent a new type of "active" granular matter. In this study, we investigate the physical, biochemical, and genetic elements that determine the static and dynamic aspects of this mode of bacterial growth for E. coli. We characterize the process of colony expansion empirically, and use discrete and continuum models to examine the extent to which our observations can be explained by the growth characteristics of non-communicating cells, coupled together by physical forces, nutrients, and waste products. Our results challenge the commonly accepted modes of bacterial colony growth and provide insight into sources of growth limitation in crowded bacterial communities.

12:15PM B28.00004 Collective motion of squirmers in a quasi-2D geometry

, ANDREAS ZÖTTL, HOLGER STARK, Technical University Berlin — Microorganisms like bacteria, algae or spermatozoa typically move in an aqueous environment where they interact via hydrodynamic flow fields. Recent experiments studied the collective motion of dense suspensions of bacteria where swarming and large-scale turbulence emerged. Moreover, spherical artificial microswimmers, so-called squirmers, have been constructed and studied in a quasi-2D geometry. Here we present a numerical study of the collective dynamics of squirmers confined in quasi-2D between two parallel walls. Because of their spherical shape the reorientation of squirmers is solely due to noise and hydrodynamic interactions via induced flow fields. This is in contrast to elongated swimmers like bacteria which locally align due to steric interactions. We study the collective motion of pushers, pullers and potential swimmers at different densities. At small densities the squirmers are oriented parallel to the walls and pairwise collisions determine the reorientation rate. In dense suspensions rotational diffusion is greatly enhanced and pushers, in particular, tend to orient perpendicular to the walls. This effects the dynamics of the emerging clusters. In very dense suspensions we observe active jamming and long-lived crystalline structures.

12:27PM B28.00005 Identifying and quantifying interactions in a laboratory swarm

, JAMES G. PUCKETT, Yale University, DOUGLAS H. KELLEY, Massachusetts Institute of Technology, NICHOLAS T. OUELLETTE, Yale University — Emergent collective behavior, such as in flocks of birds or swarms of bees, is exhibited throughout the animal kingdom. Many models have been developed to describe swarming and flocking behavior using systems of self-propelled particles obeying simple rules or interacting via various potentials. However, due to experimental difficulties and constraints, little empirical data exists for characterizing the exact form of the biological interactions. We study laboratory swarms of flying *Chironomus riparius* midges, using stereoimaging and particle tracking techniques to record three-dimensional trajectories for all the individuals in the swarm. We describe methods to identify and quantify interactions by examining these trajectories, and report results on interaction magnitude, frequency, and mutuality.

12:39PM B28.00006 Stochastic pattern transitions in large scale swarms[1]

, IRA SCHWARTZ[2], BRANDON LINDLEY[3], US Naval Research Laboratory, LUIS MIER-Y-TERAN[4], Johns Hopkins Bloomberg School of Public Health — We study the effects of time dependent noise and discrete, randomly distributed time delays on the dynamics of a large coupled system of self-propelling particles. Bifurcation analysis on a mean field approximation of the system reveals that the system possesses patterns with certain universal characteristics that depend on distinguished moments of the time delay distribution. We show both theoretically and numerically that although bifurcations of simple patterns, such as translations, change stability only as a function of the first moment of the time delay distribution, more complex bifurcating patterns depend on all of the moments of the delay distribution. In addition, we show that for sufficiently large values of the coupling strength and/or the mean time delay, there is a noise intensity threshold, dependent on the delay distribution width, that forces a transition of the swarm from a misaligned state into an aligned state. We show that this alignment transition exhibits hysteresis when the noise intensity is taken to be time dependent.

12:51PM B28.00007 Concentrating Swimming Bacteria using Funnels: Connecting Simulation Results to Simple Random-Walk Models[1] , YU-GUO TAO, GARY W. SLATER, University of Ottawa — Rectification of swimming bacteria has been observed when confined in a closed environment partitioned using porous walls with funnel shaped channels. Using Monte Carlo simulations that take into account the mechanical and thermodynamic properties of round-shape cells as well as the effect of noise on the run/tumble process, we show that the long-time behaviour of the system can be mapped onto a simple one-dimensional biased random-walk process. This implies that the many variables that are needed to describe the geometry of the system and the properties of the cells can be reduced to only two generalized variables plus the size of the system itself. We examine how these two variables depend on the initial variables and draw conclusions on the performance of the system when used as a tool to separate cells.

1:03PM B28.00008 Hysteresis in transition between individual and collective behavior in suspension of swimming bacteria , ANDREY SOKOLOV, IGOR ARANSON, Argonne National Laboratory — We present a new method for control of motility and tumbling rate of swimming bacteria Bacillus Subtilis via precise and rapid control of temperature of the bacterial suspension. Transitions between individual and collective behaviors in a response to cyclical temperature change in a range of temperatures between 5C and 35C with the rates from 0.1C/s to 1C/s were investigated. Temperature decrease typically results in a decrease of bacterial motility while preserving low tumbling rates. The temperature increase above 20C triggers a "heat shock": a significant jump in tumbling rate resulting in temporal decrease of the average swimming speed and termination of collective motion. At temperatures below 20C due to relative low tumbling rates we discovered a hysteresis in the transition between individual and collective swimming: velocity correlation length vs. average swimming speed of bacteria exhibits hysteric behavior.

1:15PM B28.00009 Flocking in Flow , NICHOLAS OUELLETTE, NIDHI KHURANA, Department of Mechanical Engineering & Materials Science, Yale University — Models of active, self-propelled particles with simple interaction rules have long been shown to produce large-scale emergent behavior reminiscent of collective animal motion seen in nature. Such model flocks can be shown to be robust against random noise terms added to the equations. But real animals, such as birds, fish, or insects, live in fluid environments, where the background flow field is nonzero and is often turbulent. In this case, the fluctuations experienced by the individuals in the aggregation are not random, but rather are correlated in space and time. We explore the impact of such spatiotemporally correlated perturbations on flocking by numerically simulating the behavior of a simple flocking model in a turbulent-like flow field produced by a kinematic simulation. The introduction of flow strongly changes the flock formation dynamics. Additionally, we find that under some conditions the background flow tends to break stable flocks into smaller units. We study these clusters, and discuss their relation to the underlying flow field.

1:27PM B28.00010 Pitfalls in mining active transport trajectories , KEJIA CHEN, BO WANG, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Single particle tracking is useful in characterizing active motion. However, there are many pitfalls in mining such data, from separating the intermittently alternating active and passive motion to fitting a model to the motion. Using statistical tools, we carefully identified such pitfalls and developed new methods to avoid them. Applying this algorithm to endosomal active transport within living cells, imaged by fluorescence microscopy with nm resolution, we observed Lévy walk behavior in multiple cells lines and for different cargo types. This Lévy walk behavior could be easily missed without those statistical tools, which can be very useful in characterizing active motion and identifying regulators in other active systems.

1:39PM B28.00011 Casimir Effect and Fluctuation-Induced Attractive Forces in Active Matter , CYNTHIA REICHHARDT, LENA LOPATINA, CHARLES REICHHARDT, Los Alamos National Laboratory — We consider the fluctuation-induced forces between plates in walls immersed in a bath of active matter, similar to the forces in the classical Casimir effect. The active matter could represent swimming bacteria. We find that the active matter causes a strong attractive force between two plates, whereas for strictly Brownian particles, there is little effect or no attraction between the plates. We discuss how the motion of the active particles, the breaking of detailed balance by the walls, and the geometry of the sample leads to a reduced particle density between the plates and produces a density-induced pressure on the plates. This result also indicates that for movable objects immersed in an active matter bath, larger objects will aggregate over time, suggesting that active matter could be used as the catalyst for a novel self-assembly method. Finally, we discuss other geometries that can produce a repulsive force between the walls, as well as the effect of flocking particles.

1:51PM B28.00012 Pattern Formation in Growing Polar Bacteria[1] , XINGBO YANG, M. CRISTINA MARCHETTI, Department of Physics, Syracuse University, DAVIDE MARENDUZZO, School of Physics and Astronomy, University of Edinburgh — We analyze a continuum model of a bacterial suspension that includes motility suppression from steric repulsion, polar alignment, and bacteria reproduction and death. Using a combination of linear stability analysis and numerical solution of the nonlinear equations, we demonstrate that the model exhibits a rich variety of emergent structures, corresponding to generic patterns seen in experiments. Motility suppression in a crowded environment gives rise to a density phase separation, regulated by the growth/death of the bacteria, as demonstrated earlier by Cates et al. [PNAS 107, 11715–11720(2010)], with spherically symmetric patterns similar to those observed in *S. typhimurium*. The addition of polar alignment yields new ring/band and swirl/spiral structures resembling those observed in *E.coli* colonies. The stationary/traveling nature of the patterns and their symmetry is classified and summarized in a phase diagram.

Session B29 GSNP: Fluctuations in Non-Equilibrium Systems 337 - Chris Jarzynski, University of Maryland

11:15AM B29.00001 Large rare fluctuations in systems with delayed dissipation , MARK DYKMAN, Michigan State University, IRA SCHWARTZ, U.S. Naval Research Laboratory — We study the probability distribution and the escape rate in noise-driven nonlinear systems with delayed dissipation. Accounting for the delay requires a significant modification of the conventional rare events theory. We develop the corresponding general formulation and find explicit results in the limiting cases. To logarithmic accuracy in the fluctuation intensity, the problem is reduced to a variational problem. It describes the most probable path followed by the system in the random rare event of interest. In contrast to Markov systems, the equations for the most probable paths are acausal due to the delay. If the dissipation and noise come from the coupling to a thermal bath, they are related by the fluctuation-dissipation relation, but our results are not limited to this case. In thermal equilibrium, the most probable path passing through a remote state has time reversal symmetry. However, again in contrast to Markov systems, one cannot uniquely define a path that starts from a state with given system coordinate and momentum. The corrections to the logarithm of the probability distribution and the escape activation energy for small dissipation delay and small noise correlation time are obtained in explicit form.

11:27AM B29.00002 Thermal rectification in non-linear structures with bulk losses , MARTIN SCHMIDT[1], Wesleyan University, TSAMPIKOS KOTTOS, Wesleyan University, Max-Planck Institute for Dynamical and Selforganizing Systems — A mechanism for thermal rectification based on the interplay between non-uniform bulk losses with nonlinearity is presented. We theoretically analyze the phenomenon using an anharmonic array of coupled oscillators coupled to the left and right with two Langevin reservoirs. A third probe thermostat (with temperature T_B) is placed in an asymmetric position in the bulk of the lattice thus breaking the translational symmetry and leading to rectification of heat flow. We note that for $T_B = 0$ this Langevin term is equivalent to a simple friction. We find that an increase of the friction strength can increase both the asymmetry and heat flux.

[1]Visiting Student from Germany

11:39AM B29.00003 An exactly solvable model of Maxwell's demon , DIBYENDU MANDAL, Department of Physics, University of Maryland, College Park, CHRISTOPHER JARZYNSKI, Department of Chemistry and Biochemistry, and Institute for Physical Science and Technology, University of Maryland, College Park — The paradox of Maxwell's demon has stimulated numerous thought experiments, leading to discussions about the thermodynamic implications of information processing. However, the field has lacked a tangible example or model of an autonomous, mechanical system that reproduces the actions of the demon. To address this issue, we introduce an explicit model of a device that can deliver work to lift a mass against gravity by rectifying thermal fluctuations, while writing information to a memory register. We solve for the steady-state behavior of the model and construct its nonequilibrium phase diagram. In addition to the engine-like action described above, we identify a "Landauer eraser" region in the phase diagram where the model uses externally supplied work to remove information from the memory register. Our model offers a simple paradigm for investigating the thermodynamics of information processing by exposing a transparent mechanism of operation.

11:51AM B29.00004 The thermodynamics of prediction , SUSANNE STILL, University of Hawaii at Manoa, DAVID SIVAK, UCSF, ANTHONY BELL, RCTN, UC Berkeley, GAVIN CROOKS, LBL, Berkeley — We expose the fundamental equivalence between model inefficiency and thermodynamic inefficiency, measured by dissipation. The dynamics of any system responding to a stochastic environmental signal can be interpreted as computing an implicit model of the driving signal. The system's state retains information about past environmental fluctuations, and a fraction of this information is predictive of future fluctuations. The remaining nonpredictive information reflects model complexity that does not improve predictive power, and thus represents the inefficiency of the model. We find that instantaneous nonpredictive information: 1) is proportional to the work dissipated due to environmental change; 2) provides a lower bound on the total average dissipated work when summed over the length of a driving protocol; 3) augments the lower bound on heat generated due to information erasure (Landauer's principle). Our results hold far from thermodynamic equilibrium and are thus applicable to a wide range of systems, including biomolecular machines. They highlight a profound connection between the effective use of information and efficient thermodynamic operation: any system constructed to keep memory about its environment and to operate with maximal energetic efficiency has to be predictive.

12:03PM B29.00005 Geometry of thermodynamic control , DAVID SIVAK, University of California, San Francisco, PATRICK ZULKOWSKI, MICHAEL DEWEESE, University of California, Berkeley, GAVIN CROOKS, Lawrence Berkeley National Laboratory — A fundamental problem in modern thermodynamics is how a molecular-scale machine performs useful work, while operating away from thermal equilibrium without excessive dissipation. We show that when a thermodynamic system is driven from equilibrium, in the linear response regime, the space of controllable parameters has a Riemannian geometry induced by a generalized friction tensor. This metric structure controls the dissipation of finite-time transformations, and bestows optimal protocols (geodesics on the Riemannian manifold) with many useful properties. We exploit this geometric insight to construct closed-form expressions for minimal-dissipation protocols for a model system of a particle diffusing in a one-dimensional harmonic potential, where the spring constant, inverse temperature, and trap location are adjusted simultaneously. This simple model has a surprisingly rich geometry, which we test via a numerical implementation of the Fokker-Planck equation.

12:15PM B29.00006 Clinical application of fluctuation dissipation theory - Prediction of heart rate response to spontaneous breathing trial , LIANG R. NIESTEMSKI, MAN CHEN, Physics & Astronomy, Rice University, Houston, TX, ROBERT PREVOST, MICHAEL MCRAE, Bioengineering, Rice University, Houston, TX, SHARATH CHOLLETI, GABRIEL NAJARRO, TIMOTHY G. BUCHMAN, Emory University, Atlanta, GA, MICHAEL W. DEEM, Physics & Astronomy, Bioengineering, Rice University, Houston, TX — Contrary to the traditional view of the healthy physiological state as being a single static state, variation in physiologic variables has more recently been suggested to be a key component of the healthy state. Indeed, aging and disease are characterized by a loss of such variability. We apply the conceptual framework of fluctuation-dissipation theory (FDT) to predict the response to a common clinical intervention from historical fluctuations in physiologic time series data. The non-equilibrium FDT relates the response of a system to a perturbation to natural fluctuations in the stationary state of the system. We seek to understand with the FDT a common clinical perturbation, the spontaneous breathing trial (SBT), in which mechanical ventilation is briefly suspended while the patient breathes freely for a period of time. As a stress upon the heart of the patient, the SBT can be characterized as a perturbation of heart rate dynamics. A non-equilibrium, but steady-state FDT allows us to predict the heart rate recovery after the SBT stress. We show that the responses of groups of similar patients to the spontaneous breathing trial can be predicted by this approach. This mathematical framework may serve as part of the basis for personalized critical care.

12:27PM B29.00007 Cumulant generating function formula of heat transfer in ballistic systems with lead-lead coupling and general nonlinear systems , HUANAN LI, National University of Singapore — Based on a two-time observation protocol, we consider heat transfer in a given time interval t_M in a lead-junction-lead system taking coupling between the leads into account. In view of the two-time observation, consistency conditions are carefully verified in our specific family of quantum histories. Furthermore, its implication is briefly explored. Then using the nonequilibrium Green's function method, we obtain an exact formula for the cumulant generating function for heat transfer between the two leads, valid in both transient and steady-state regimes. Also, a compact formula for the cumulant generating function in the long-time limit is derived, for which the Gallavotti-Cohen fluctuation symmetry is explicitly verified. In addition, we briefly discuss Di Ventra's repartitioning trick regarding whether the repartitioning procedure of the total Hamiltonian affects the nonequilibrium steady-state current fluctuation. All kinds of properties of nonequilibrium current fluctuations, such as the fluctuation theorem in different time regimes, could be readily given according to these exact formulas. Finally a practical formalism dealing with cumulants of heat transfer across general nonlinear quantum systems is established based on field theoretical/algebraic method.

12:39PM B29.00008 Fluctuation Relations for Current Components in Mesoscopic Electric Circuits , NIKOLAI SINITSYN, Los Alamos National Lab, SRIRAM GANESHAN, University of Maryland, College park — Discovery of Fluctuation Theorems (FTs) for non-equilibrium systems led to optimism that they might serve as universal laws that had long been missing from the study of nonequilibrium systems. Surprisingly, recent experimental work has shown that the FTs can fail in an electric circuit, but could be salvaged under the experimental conditions if the affinity parameter is suitably renormalized by a factor of 0.1. Motivated by this new experimental result we present a new class of fluctuation relations, to which we will refer as "Fluctuation Relations for Current Components" (FRCCs). Unlike standard fluctuation theorems, FRCCs follow from the seemingly trivial fact that to know statistics of particle currents, it is sufficient to know only statistics of single particle geometric trajectories while the information about time moments, at which particles make transitions along such trajectories, is irrelevant. We also show that FRCCs are robust in the sense that they do not depend on some basic types of electron interactions and some quantum coherence effects.

12:51PM B29.00009 The Dependence of Heat Fluctuation Theorem on an Initial Distribution , KWANGMOO KIM, HYUNGGYU PARK, School of Physics, Korea Institute for Advanced Study, Seoul, South Korea, CHULAN KWON, Department of Physics, Myongji University, Yongin, South Korea — The fluctuation theorem (FT) proven for work does not hold for heat even in the long time limit. As the two quantities differ by the change in energy at the initial and final times, we suspect that the memory of an initial distribution may remain in the heat production accumulated for a long time. We investigate the dependence of the large deviation function (LDF) and FT on the temperature of the initial equilibrium distribution for the motion of a Brownian particle in a harmonic potential dragged with a constant velocity. The conventional saddle point integration for the LDF used in van Zon and Cohen, Phys. Rev. Lett. **91**, 110601 (2003) is found to fail as the saddle point approaches asymptotically the singularity at the branch point in the long time limit. We develop a new mathematical method to resolve this problem and confirm it with numerical simulations. As a result, the tail of LDF, i.e., a region of rare events, is shown to depend remarkably on the initial temperature and also causes more types of modifications of FT's than the so called extended FT proposed by van Zon and Cohen. We expect that our method can be applied to the investigation of the dependence of initial memories in other nonequilibrium systems.

1:03PM B29.00010 Threshold for everlasting initial memory for rare events in equilibration processes , JAE SUNG LEE, Korea Institute for Advanced Study, CHULAN KWON, Myoung-ji Unioversity, HYUNGGYU PARK, Korea Institute for Advanced Study — Conventional wisdom indicates that initial memory should decay away exponentially in time for general (noncritial) equilibration processes. In particular, time-integrated quantities such as heat are presumed to lose initial memory in a sufficiently long-time limit. However, we show that the large deviation function of time-integrated quantities may exhibit initial memory effect even in the infinite-time limit, if the system is initially prepared sufficiently far away from equilibrium. For a Brownian particle dynamics, as an example, we found a sharp finite threshold rigorously, beyond which the corresponding large deviation function contains everlasting initial memory. The physical origin for this phenomenon is explored with an intuitive argument and also from a toy model analysis.

1:15PM B29.00011 Fluctuation theorems and entropy production with odd-parity variables[1] , HYUNGGYU PARK, Korea Institute for Advanced Study, HYUN KEUN LEE, University of Seoul, CHULAN KWON, Myongji University — We show that the total entropy production in stochastic processes with odd-parity variables (under time reversal) is separated into three parts, only two of which satisfy the integral fluctuation theorems in general. One is the usual excess contribution, which can appear only transiently and is called non-adiabatic. Another one is attributed solely to the breakage of detailed balance. The last part not satisfying the fluctuation theorem comes from the steady-state distribution asymmetry for odd-parity variables, which is activated in a non-transient manner. The latter two parts combine together as the house-keeping (adiabatic) contribution, whose positivity is not guaranteed except when the excess contribution completely vanishes. Our finding reveals that the equilibrium requires the steady-state distribution symmetry for odd-parity variables independently, in addition to the usual detailed balance.

[1]This work was supported by Mid-career Researcher Program through NRF grant (No. 2010-0026627) funded by the MEST.

1:27PM B29.00012 A novel nature in nonequilibrium entropy production with odd-parity variables , CHULAN KWON, Myongji University, HYUNGGYU PARK, Korea Institute of Advanced Studies, JOONHYUN YEO, Konkuk University, HYUN KEUN LEE, University of Seoul — We present our recent finding about a novel nature in nonequilibrium entropy production for systems with odd-parity variables under time reversal. In the presence of irreversible forces the entropy production ΔS_{env} transferred from system to environment is not equal to Q/T where Q is the heat transfer and T the temperature of heat bath. We consider a dissipative force applied by external agent in addition to that given by heat bath. Then ΔS_{env} has extra contribution to Q/T for which an appropriate physical explanation is still open. Another example for irreversible force is a form of $-A\cdot\vec{p}/m$ for antisymmetric matrix A which is realized by a Lorentz force in a uniform magnetic field. In spite of no heat dissipation ΔS_{env} has a nonvanishing positive contribution. We find that it is due to a nonzero phase space current remaining through stochastic average, which is in fact a nonzero average force. Basically it plays the same role as a nonzero position space current observed in system with even variables only. We suppose interesting situations for different types of irreversible forces.

1:39PM B29.00013 About the Equivalence of Phase Retrieval Methods Employed in Nonlinear Spectroscopy and Microscopy[1] , LASZLO UJJ[2], Department of Physics, SSE, University of West Florida, ROHAN HEMASINHA[3], Department of Mathematics & Statistics, University of West Florida — It is well known that the generalized Kramers-Kronig relationship is able to retrieve the phase of a signal from measured power spectra. This phase recovery is a critical procedure in nonlinear optical spectroscopy, e.g. coherent Raman time domain or frequency domain spectroscopy. Several other methods have been developed and being used in the past: notably, nonlinear fitting and maximum entropy method. A firm mathematical comparison of the methods including the effects of final signal sampling and their merit of fidelity will be presented. Attention is given to numerical implementation of the phase retrieval procedure to put it into practice in coherent anti-Stokes Raman microscopy. Phase retrieval examples using all the above methods are taken from earlier and recently recorded spectra.

1:51PM B29.00014 Theory of zero-bias anomaly in low-temperature inelastic tunneling spectroscopy , YOSHIHIRO ASAI, Nanosystem Research Institute (NRI) "RICS", AIST, Tsukuba, Ibaraki 305-8568, Japan — A small zero-bias anomaly (ZBA) in inelastic tunneling spectroscopy (IETS) through nonmagnetic quantum wires has been suggested experimentally at low temperatures [1,2]. Here, the mechanism is discussed theoretically with special attention paid to contributions from low energy phonons [3]. Our theoretical calculations, using an electron-phonon coupling model, predict the ZBA. While experimental information is still limited, our theoretical result agrees with existing experiments. The theory provides useful information, characterizing the ZBA in a nonmagnetic junction.

2:03PM B29.00015 Computation of Microcanonical Entropy Differences in Atomistic Computer Simulation[1] , SERGIO DAVIS, Departamento de Física, Facultad de Ciencias, Universidad de Chile — In this work, two alternative methods to compute thermodynamic entropy differences $\Delta S = S(E_2) - S(E_1)$ between two microcanonical states (produced via atomistic computer simulation, either deterministic or stochastic) at total energies E_1 y E_2 are presented. The first method is straightforward to implement, as it only needs potential energy samples from both simulations; however, it requires that fluctuations of potential energy are similar in magnitude to the energy difference ΔE between the states. It is therefore best suited for simulations in small systems (hundred of atoms). The second method, based on Bayesian probability and information theory, removes this limitation: it allows the computation of the entropy curve $S(E)$ for a wide range of energies and therefore is a viable alternative to methods such as Wang-Landau Monte Carlo. It is based on inferring the configurational density of states (CDOS) from potential energy samples. A simple model for the CDOS of embedded atom metals is presented and tested in Au and Cu by computing entropy and free energy differences.

11:15AM B30.00001 Coarsening of firefighting foams containing fluorinated hydrocarbon surfactants , MATTHEW J. KENNEDY[1], JOHN A. DOUGHERTY[2], NICHOLAS OTTO[3], MICHAEL W. CONROY, BRADLEY A. WILLIAMS, RAMAGOPAL ANANTH, JAMES W. FLEMING, Naval Research Laboratory — Diffusion of gas between bubbles in foam causes growth of large bubbles at the expense of small bubbles and leads to increasing mean bubble size with time thereby affecting drainage. Experimental data shows that the effective diffusivity of nitrogen gas in aqueous film forming foam (AFFF), which is widely used in firefighting against burning liquids, is several times smaller than in 1% sodium dodecyl sulfate (SDS) foam based on time-series photographs of bubble size and weighing scale recordings of liquid drainage. Differences in foam structure arising from foam production might contribute to the apparent difference in the rates of coarsening. AFFF solution produces wetter foam with initially smaller bubbles than SDS solution due in part to the lower gas-liquid surface tension provided by the fluorosurfactants present in AFFF. Present method of foam production generates microbubble foam by high-speed co-injection of surfactant solution and gas into a tube of 3-mm diameter. These results contribute to our growing understanding of the coupling between foam liquid fraction, bubble size, surfactant chemistry, and coarsening.

11:27AM B30.00002 Competition between phase separation and crystallization in attractive colloids , BARBARA FRISKEN, ARTHUR BAILEY, JUAN SABIN[1], GABRIEL ESPINOSA[2], Simon Fraser University, Canada — We will present results from recent experiments on Earth and on the International Space Station investigating the interplay between phase separation and crystallization in samples prepared in the three-phase region (gas-liquid-crystal) of the phase diagram of a colloid-polymer mixture. On Earth, our samples first separate into a colloid-rich phase and a colloid-poor phase, with crystals forming in the colloid-rich phase. The denser phases sediment as expected. In microgravity, photographic images obtained in the BCAT-5 experiment reveal phase separation with crystal formation in the denser phase, where the phase separation continues normally until the dominant length scale is about 25% of the cell thickness, at which point both phase separation and crystal growth are arrested before macroscopic phase separation can occur. We propose that this arrest occurs because a crystalline network forms in the liquid phase and that the gas-liquid surface tension is not sufficient to overcome the stiffness of this network.

11:39AM B30.00003 Colloidal Wigner Crystals Near the Melting Transition , EMILY RUSSELL, DAVID WEITZ, Harvard University — We demonstrate the formation of colloidal "Wigner" crystals at low particle volume fraction. Particles are suspended in a nonpolar solvent and charged by the addition of a small amount of surfactant, generating a long-range interparticle repulsion which induces crystallization above a critical volume fraction of order 10%. Confocal microscopy allows us to study in detail the three-dimensional structure and dynamics of these colloidal crystals as we vary the volume fraction, and we find a growing population of especially mobile particles with large local Lindemann parameter as we approach the critical volume fraction. We discuss our results and the implications of our findings to competing ideas of the mechanism of bulk crystal melting.

11:51AM B30.00004 Visualization of colloidal liquid nucleation induced by Critical Casimir forces , DUC NGUYEN, PhD, PETER SCHALL, Dr — We show that with precise temperature control of critical Casimir forces we achieve reversible control of colloidal gas-liquid. The exquisite temperature control of the potential allows us to even tune the degree of supersaturation of the liquid phase. We use a confocal microscopy to elucidate the nucleation process on the single particle level: We determine the Gibbs free energy, interfacial tension and chemical potential of the liquid aggregates directly from their size distribution. We estimate the interfacial tension of the aggregates at different degree of supersaturation directly from the particle potential and pair correlation function using Kirkwood and Buff theory. A good agreement between the two methods provides new insight into the gas-liquid transition.

12:03PM B30.00005 Shear Driven Aggregation in Latex Colloids , SURESH AHUJA, Retired — Reynolds number is small in colloidal flow and therefore, colloidal volume fraction and Peclet number are important. AS the volume fraction and attractive coupling between particles increase, relaxation time and Weisenberg number become significant. Shear-induced aggregation of latex colloids is due to the interplay between the shear-induced formation and breakage of latex .particles. While particle size is limited by breakage, their number density increases with the shearing-time. Upon cessation of shear, the particles interconnect into an assembly held by grainy bonds. It results in increase in yield stress and dynamic modulus. A contact model enables aggregates maintaining their structures under low stress while being restructured under high stress. Modeling involves solution of Navier- Stokes equation with moving particles as boundary condition for the flow like using the Lattice Boltzmann approach or by using (accelerated) Stokesian Dynamics. Alternate approach is to model the fluid phase by soft repulsive particles with pair-wise noise and friction, known as dissipative particle dynamics (DPD). This method by construction produces full inertial hydrodynamics, but applying the correct fluid-particle boundary condition is non-trivial. Both particle to particle and particle to wall collisions can be considered using Johnson-Kendall- Roberts (JKR) analysis of collision dynamics of dissipative forces using a soft-sphere modeling technique. Our experimental work used emulsion polymerized latex that was subjected to steady and dynamic shear. Yield stress, dynamic modulus and relaxation time increased on shearing in conjunction with changes in aggregate size.

12:15PM B30.00006 Domain, Stripe, and Pattern Formation for Colloids on Optical Trap Arrays , DANIELLE MCDERMOTT, University of Notre Dame, JEFFERY AMELANG, California Institute of Technology, LENA LOPATINA, CYNTHIA REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — We examine pattern formation of colloids atop a square periodic substrate using large scale numerical simulations. The pins forming the substrate are modeled with a muffin-tin potential which is flat with localized traps. We show that with 4 colloids per pinning site the system has triangular ordering and with 5 colloids per site it has square ordering. We study intermediate fillings and identify a rich variety of distinct ordering regimes including disordered grain boundaries, crystalline stripe structures, superlattice orderings, and disordered patches of multiple phases. These different regimes are characterized with a Voronoi analysis, energy dispersion plots, and ordination of domains. We extend our studies to a wide range of other fillings which feature similar boundary formation patterns. Our results show that periodic substrates of muffin-tin potentials can be used to tailor grain boundary formation.

12:27PM B30.00007 Anisotropic colloids for building complex molecular structures using critical Casimir effect , TRUC ANH NGUYEN, University of Amsterdam, DANIELA KRAFT, New York University, SANDRA VEEN, PETER SCHALL, University of Amsterdam — Here, we present a new way to build complex colloidal scale structures using critical Casimir forces on anisotropic colloids. These forces arise from the confinement of critical solvent fluctuations between the particle surfaces and allow temperature-control over the particle interactions. We use doublet particles made of polymethyl-methacrylate (PMMA) and exhibiting anisotropic surface charge densities, suspended in a binary liquid mixture. By controlling the applied temperatures of the system, we can tune the particle interactions of the two ends of the particles to observe different superstructures formed in time and space: at low temperature, the particles are randomly distributed and represent a gas phase; however, at higher temperatures, the particles form long chain-like structures and cubic crystal structures depending on the temperature difference to the solvent phase separation. This opens new opportunities to assemble complex building blocks for nano- and micro-devices.

12:39PM B30.00008 Direct observation of the nucleation in colloidal solid-solid transitions[1] , YI PENG, FENG WANG, ZIREN WANG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — Solid-solid phase transitions are ubiquitous in nature, but their microscopic mechanisms remain poorly understood. We employed thermally sensitive microgels to study the solid-solid transitions between square and triangular lattices in colloidal thin films. Two types of nucleation processes were directly observed by video microscopy and studied at the single-particle level. Under low flow rates, the nucleation is a two-step process: square lattice → liquid nucleus → triangle nucleus and its precursor is a local particle-exchange loop, whereas under high flow rates the nucleus of the triangle lattice forms directly from a dislocation pair by a martensitic mechanism. We measured the critical nucleus size, the energy barrier height and the hysteresis loop of the solid-solid transitions. Our results cast new light to solid-solid transitions in carbon systems, nano-crystals and geophysics.

12:51PM B30.00009 Frustrated Ordering of Colloidal Crystals in Spatially Varying Potentials , VISHAL SONI, WILLIAM T.M. IRVINE, University of Chicago — Frustrated ordering processes are of wide interest in condensed matter systems. Experiments on interfacial colloidal systems have resulted in several recent insights into the two dimensional ordering of crystalline lattices frustrated by Gaussian curvature. We study the ordering of two-dimensional lattices of colloids frustrated by spatially varying dielectrophoretic forces. In particular, we investigate the role of topological defects in organizing the conformal-crystal like ground state and the defect dynamics that lead to equilibration as the applied dielectrophoretic force is increased.

1:03PM B30.00010 Preparation of monodisperse microspheres from the Laplace pressure induced droplet formation in micromolds , CHANG-HYUNG CHOI, JONGMIN KIM, SUNG-MIN KANG, Chungnam National University, JINKEE LEE, Sungkyunkwan University, CHANG-SOO LEE, Chungnam National University — Monodisperse microspheres play critical roles in many applications such as micro-electromechanical systems (MEMS), chemical release systems, optical materials and various biological applications. Although microfluidic systems have been developed for producing monodisperse microspheres, it still definitely requires pressure driven flow for continuous fluid injection as well as use of surfactant to achieve their uniformity. Here, we present a novel molding method that generates monodisperse microspheres through surface-tension-induced flow. Two immiscible fluids that consist of photocurable monomer and hydrophobic oil are sequentially applied onto the mold. The mold geometry results in Laplace pressure induced droplet formation, and these droplets formed are individually localized into each micromold. Photopolymerization of the droplets allow for the formation of polymer microspheres with narrow size distribution (CV=1.9%). We obtain the microspheres with diameter ranging from 20 to 300 μm by modulating mold dimensions. We provide a synthesis method to produce microspheres in micromolds for various reaction schemes: UV-polymerization, sol-gel reactions and colloidal assemblies.

1:15PM B30.00011 Formation of Uniform Hollow Silica microcapsules , HUAN YAN, CHANJOONG KIM, Liquid Crystal Institute, Kent State University — Microcapsules are small containers with diameters in the range of 0.1 – 100 μm. Mesoporous microcapsules with hollow morphologies possess unique properties such as low-density and high encapsulation capacity, while allowing controlled release by permeating substances with a specific size and chemistry. Our process is a one-step fabrication of monodisperse hollow silica capsules with a hierarchical pore structure and high size uniformity using double emulsion templates obtained by the glass-capillary microfluidic technique to encapsulate various active ingredients. These hollow silica microcapsules can be used as biomedical applications such as drug delivery and controlled release.

1:27PM B30.00012 Interstitials in 2D colloidal crystals , LICHAO YU, SUNGCHEOL KIM, Brown University, ALEXANDROS PERTSINIDIS, Sloan-Kettering Institute, XINSHENG LING, Brown University — Point defects in crystalline solids are important in many areas of condensed matter physics, ranging from the mechanical properties of metals, to supersolidity in quantum solids, and most recently the magnetic properties of graphene. A key question to point defects is how they diffuse in the crystalline lattice. Colloidal crystals provide a perfect model system for studying the dynamics of point defects, since the kinetic pathways of diffusion can be identified in direct real-time video imaging experiments. Here we report an experimental study of another type of point defects: interstitials. We found that interstitial diffusion in a 2D colloidal crystal is also dominated by a dislocation pair unbinding-binding process. Similar to vacancies, interstitial diffusion exhibits strong memory effects. However, the contrast lies in the observation that the interstitials, as quasi-particles, diffuse faster than vacancies. We propose that higher diffusion constant of the interstitials is a result of the suppression of the Peierls barrier for the edge dislocations by the excess strain created by the extra particle(s). This work was supported by NSF-DMR.

1:39PM B30.00013 Effects of Particle Shape on Growth Dynamics at Edges of Evaporating Drops of Colloidal Suspensions[1] , PETER J. YUNKER, Harvard University, MATTHEW A. LOHR, TIM STILL, University of Pennsylvania, ALEXEI BORODIN, Massachusetts Institute of Technology, D.J. DURIAN, A.G. YODH, University of Pennsylvania — We study the influence of particle shape on growth processes at the edges of evaporating drops. Aqueous suspensions of colloidal particles evaporate on glass slides, and convective flows during evaporation carry particles from drop center to drop edge, where they accumulate. The resulting particle deposits grow inhomogeneously from the edge on the air-water interface in two-dimensions. The deposition front, or growth line, varies in space and time. Measurements of the fluctuations of the deposition front during evaporation enable us to identify distinct growth processes. Interestingly, three distinct growth processes were discovered in the evaporating colloidal suspensions by tuning particle shape-dependent capillary interactions and thus varying the microscopic rules of deposition. Sphere deposition exhibits a classic Poisson like growth process; deposition of slightly anisotropic particles, however, appears to belong to the Kardar-Parisi-Zhang (KPZ) universality class, and deposition of highly anisotropic ellipsoids appears to belong to a third universality class, characterized by KPZ fluctuations in the presence of quenched disorder.

1:51PM B30.00014 Non-equilibrium Ionic Assemblies of Oppositely Charged Colloids , RUI ZHANG, PRATEEK JHA, MONICA OLVERA DE LA CRUZ, Northwestern University — The structure and evolution kinetics of non-equilibrium clusters formed in a solution of oppositely charged colloids are analyzed by a kinetic Monte Carlo simulation scheme. A wide range of dynamic cluster configurations are obtained by varying the various external parameters controlling the interaction strength between colloids, screening length, and packing density of colloids. At low-salt concentrations, clusters with structures ranging from NaCl-type cubic aggregates to fibril-like chains are observed, while at high-salt concentrations, disordered compact clusters are observed. A chain-folding barrier model is proposed to explain the kinetically trapped fibril-like assemblies. In higher-density solutions, ionic clusters of bigger size and percolated gel structures are observed. Our work demonstrates the structural richness of non-equilibrium ionic assemblies of oppositely charged colloids and elucidates the effect of ionic correlations, not captured by mean field models such as the modified Poisson-Boltzmann approaches, in determining the structure of assemblies of oppositely charged colloids. These "ionic composites" hold great promise in a variety of emerging applications such as templated polymerization of charged molecules and assembly of charged particles.

2:03PM B30.00015 Directional Entropic Forces in Hard Colloids , GREG VAN ANDERS, KHALID AHMED, ROSS SMITH, MICHAEL ENGEL, SHARON GLOTZER, University of Michigan — Based on known results from the literature of hard particles we introduce the concept of entropically patchy particles – particles that bind with angular specificity entirely due to their geometry via directional entropic forces or "bonds". Unlike ordinary patchy particles, in which "valence" vis-a-vis angular specificity is dictated by microscopic energetic considerations (sticky patches), entropic forces causing the binding of particles at entropic patch sites are emergent. Using basic examples we show both theoretically and computationally that we can alter the geometry of a particle to create an entropic patch and tune the resulting effective pair potential in such a way that it can lead to angularly specific binding, even in the absence of depletants.

Session B31 DPOLY: Focus Session: Nano to Meso-Scale Structure in Ordered Soft Matter: Liquid Crystal Structure, Dynamics and Function I 339 - Alberto Fernandez de las Nieves, Georgia Institute of Technology

11:15AM B31.00001 Self-Assembly of Polyhedral Oligomeric Silsesquioxane-Based Giant Molecular Shape Amphiphiles , YIWEN LI, STEPHEN CHENG, Department of Polymer Science, The University of Akron, Akron, OH, 44325 — A series of giant molecular shape amphiphiles based on functional polyhedral oligomeric silsesquioxane (POSS) particles was designed and synthesized. The supramolecualr structures of these assemblies along with the resulting ordered structures are fully investigated to determine their structure-property relationships. For example, functional POSS cages with different surface chemistry and sizes were employed to construct dumbbell- and snowman-like molecular Janus particles with various symmetry breakings. These particles could self-organize into hierarchically ordered supramolecular structures in the bulk. Another illustrating example is a series of novel giant surfactants, lipids and gemini surfactants possessing a hydrophilic POSS head and polymer or alkyl chain tails. Diverse architectures of this class of materials have been constructed and their self-assembly processes in solution and bulk state have been discussed. This set of research results not only has general implications in the basic physical principles underlying their self-assembly behaviors, but also create unique materials for developing advanced technologies by combining the properties of hybrid materials

11:27AM B31.00002 Nanoparticle Solubility in Liquid Crystalline Defects , JONATHAN K. WHITMER, Department of Chemical and Biological Engineering, University of Wisconsin–Madison, JULIO C. ARMAS-PEREZ, Institute for Molecular Engineering, University of Chicago, ABHIJEET A. JOSHI, TYLER F. ROBERTS, Department of Chemical and Biological Engineering, University of Wisconsin–Madison, JUAN J. DE PABLO, Institute for Molecular Engineering, University of Chicago — Liquid crystalline materials often incorporate regions (defects) where the orientational ordering present in the bulk phase is disrupted. These include point hedgehogs, line disclinations, and domain boundaries. Recently, it has been shown that defects will accumulate impurities such as small molecules, monomer subunits or nanoparticles. Such an effect is thought to be due to the alleviation of elastic stresses within the bulk phase, or to a solubility gap between a nematic phase and the isotropic defect core. This presents opportunities for encapsulation and sequestration of molecular species, in addition to the formation of novel structures within a nematic phase through polymerization and nanoparticle self-assembly. Here, we examine the solubility of nanoparticles within a coarse-grained liquid crystalline phase and demonstrate the effects of nanoparticle size and surface interactions in determining sequestration into defect regions.

11:39AM B31.00003 Liquid Crystal Phase Transition driven three-dimensional Quantum Dot Organization[1] , ANDREA L. RODARTE, R.J. PANDOLFI, S. GHOSH, L.S. HIRST, University of California, Merced — We use a nematic liquid crystal (LC) to create organized assemblies of CdSe/ZnS core/shell quantum dots (QDs). At the isotropic-nematic LC phase transition, ordered domains of nematic LC expel the majority of dispersed QDs into the isotropic domains. The final LC phase produces a series of three dimensional columnar QD assemblies that are situated at defect points in the LC volume. Within each assembly the QD emission is spectrally-red-shifted due to resonant energy transfer. We use this spectral shift as a measure of the inter-dot separation and find that the QDs are packed uniformly in these assemblies over distances of microns between the glass plates of a standard LC cell. In addition, because the QD clusters form at defects, we can deterministically control the location of the assemblies by seeding the LC cell with defect nucleation points.

11:51AM B31.00004 Ordering of Lyotropic Chromonic Liquid Crystal Films In Cylindrical Micropost Arrays[1]

, MARCELLO CAVALLARO, University of Pennsylvania, Department of Chemical and Biomolecular Engineering, MATTHEW LOHR, DANIEL BELLER, University of Pennsylvania, Department of Physics and Astronomy, LAURA LADERMAN, Swarthmore College, Department of Physics, KATHLEEN STEBE, University of Pennsylvania, Department of Chemical and Biomolecular Engineering, RANDALL KAMIEN, University of Pennsylvania, Department of Physics and Astronomy, PETER COLLINGS, Swarthmore College, Department of Physics, ARJUN YODH, University of Pennsylvania, Department of Physics and Astronomy — The use of micropost arrays is explored as a means for controlling self-assembly and director alignment in nematic chromonic liquid crystal (CLC) films. Experiment and numerical solutions reveal that the micropost arrays induce bistable director alignment in the film, along either diagonal of a square micropost lattice. We demonstrate stabilization of large domains of a single director orientation by rubbing the substrate surface along a single diagonal, a procedure which biases planar CLC director alignment in the film. Additionally, by varying the rubbing angle we investigate the competition between alignment via micropost patterns versus substrate rubbing, and we find the resulting assemblies to be largely controlled by micropost geometry. Variation of micropost layout, spacing and dimensions leads to further interesting self-assembled patterns and defect geometries.

12:03PM B31.00005 Modelling liquid crystal elastomers and potential application as a reversibly switchable adhesive[1]

, JAMES ADAMS, University of Surrey — Liquid crystal elastomers (LCEs) are rubbery materials that composed of liquid crystalline polymers (LCPs) crosslinked into a network. The rod-like mesogens incorporated into the LCPs are have random orientations in the high temperature isotropic phase, but can adopt the canonical liquid crystalline phases as the temperature is lowered. Smectic liquid crystal elastomers have highly anisotropic mechanical behaviour. This arises in side chain smectic-A systems because the smectic layers behave as if they are embedded in the rubber matrix [1]. The macroscopic mechanical behaviour of these solids is sensitive to the buckling of the layers, so is a multiscale problem. A coarse grained free energy that includes the fine-scale buckling of the layers has been developed [2], which enables continuum modelling of these systems. In the first part of this talk I present a model of the mechanical behaviour of side chain smectic elastomers. The properties of nematic LCEs, such as their high loss tangent, and mechanical strain hardening, might enable them to be used as reversibly switchable pressure sensitive adhesive (PSA). PSAs are typically made from viscoelastic polymers. The quality of their adhesion can be measured by the *tack energy*, which is the work required to separate two bodies. To obtain a high tack energy a PSA should be capable of a large strain. It should strain soften at low strain to produce crack blunting, and then strain harden at high strain to stiffen the fibrils formed late in the debonding process. I will present a model of the tack energy of weakly crosslinked nematic polymers. To describe the constitutive properties of this system the nematic dumbbell model of Maffettone *et al.* was used [3]. This constutitive model was then combined with the block model of Yamaguchi *et al.* describing PSAs [4]. It was found that the parallel orientation of the nematic has a higher tack energy than both the isotropic and the perpendicular director orientation [5].

12:39PM B31.00006 Compliant random fields in gels formed from side-chain liquid crystalline polymers

, PAUL GOLDBART, FANGFU YE, Georgia Institute of Technology, BING LU, XIANGJUN XING, Shanghai Jiao Tong University — Localized polymer-chain backbones in gels formed from side-chain liquid crystalline polymers serve to create random fields that induce local orientational order of the nematogenic pendants of the side chains. These random fields differ, however, from conventional ones, in that they are compliant, and thus themselves undergo thermal fluctuations. We develop a free energy that describes local nematic ordering in presence of such compliant random fields. In particular, we show that, as a result of this compliance, the free energy has a qualitatively new structure, unattainable via truly static random fields. We discuss the physical implications this free energy, focusing on the consequences of the compliant nature of the random fields.

12:51PM B31.00007 Phase Behavior of Semi-flexible-Coil Block Copolymers Studied by Monte Carlo Simulations

, TAO WEI, ROBERT RIGGLEMAN, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — Semi-flexible/coil and rod/coil polymers have attracted increasing interest in the applications of organic electronics and biomaterials due to their novel supramolecular structures with nanoscale architecture and tunable domain size. The coupling of microphase separation and liquid-crystalline ordering, stemming from chain rigidity, yields complex phase behaviors. In this work, phase morphologies and phase diagram of semi-flexible/coil block copolymers were identified with efficient Theoretical informed coarse-grained Monte Carlo (TIMC) simulations, which tracks the local density of each grid, rather than computationally demanding pair-wise interactions. Besides the common Flory-Huggins interactions between dissimilar components, we incorporate anisotropic interactions through a Maier-Saupé potential. Due to the increased complexity of semi-flexible polymer, parameter number is significantly larger compared to fully flexible polymers. We will illustrate the TIMC method for semi-flexible/coil polymers and examine fluctuation effect on various phase diagrams. We demonstrate the influence of the relative strength of Maier-Saupé parameter to Flory-Huggins parameter, as well as the geometric factors that characterize the size of the semi-flexible block relative to the coil block.

1:03PM B31.00008 Competition of Elasticity and Flexoelectricity for bistable alignment of nematics on patterned substrates

, TIMOTHY ATHERTON, JAMES ADLER, Tufts University — We show that patterned surfaces can promote bistable configurations of nematics for reasons other than the symmetry of the surface. Numerical and analytical calculations reveal that a nematic liquid crystal in contact with a striped surface is subject to the competing aligning influences of elastic anisotropy, differing energy cost of various types of deformation, and flexoelectricity, curvature-induced spontaneous polarization. These effects favor opposing ground states where the azimuthal alignment is, respectively, parallel or perpendicular to the stripes. Material parameters for which the effect might be observed lie within the range measured for bent-core nematogens.

1:15PM B31.00009 Effect of ionic additives on elasticity of lyotropic chromonic liquid crystal[1] , SHUANG ZHOU, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, Ohio 44242, ADAM J. CERVENKA, Bates College, Lewiston, ME 04240, YOGESH SINGH, Department of Physics, Kent State University, Kent, Ohio 44242, LUANA T. TORTORA, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, Ohio 44242, CARMEN C. ALMASAN, Department of Physics, Kent State University, Kent, Ohio 44242, OLEG D. LAVRENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, Ohio 44242 — Using a magnetic Frederiks transition technique, we determine how the splay K_1 and bend K_3 elastic constants of lyotropic chromonic liquid crystal Sunset Yellow (SSY) depend on concentration of ionic additives, sodium chloride (NaCl) and magnesium sulfate ($MgSO_4$). Both salts increase the ratio K_1/K_3, by mainly increasing K_1 ($MgSO_4$) or mainly decreasing K_3 (NaCl). The effects are attributed to the screening of electrostatic repulsions of chromonic molecules, which is expected to increase the contour length (thus increasing K_1) and to decrease the persistence length (thus decreasing K_3) of the chromonic aggregates in which the molecules are stacked face-to-face. As in salt-free SSY, the ratio K_1/K_3 increases when the temperature decreases.

1:27PM B31.00010 Tactoids and Defects in Nematic-Isotropic Phase Transition in Lyotropic Chromonic Liquid Crystal[1] , YOUNG-KI KIM, OLEG D. LAVRENTOVICH, Liquid crystal institute and chemical physics interdisciplinary program, Kent state university, Kent, OH, USA — We explore the structure of nuclei (tactoids) and topological defects (disclinations) in the first-order nematic-isotropic phase transition in self-assembled lyotropic chromonic liquid crystals. The shape of tactoids is determined by orientational elasticity of the liquid crystal, surface tension, and surface anchoring of the director. The positive tactoids (nuclei of the nematic phase) show two pointed ends (cusps). The negative tactoids (nuclei of the isotropic phase) show a variety of shapes, with one, two, or three cusps, depending on whether they nucleate at the core of disclinations of strength 1/2, in a homogeneous nematic, or at the core of a (-1/2) disclination, respectively. Zero-cusp and four-cusp formations are also possible at the core of stabilized disclinations of strength 1 and -1, respectively. The results demonstrate a profound role of surface tension and its anisotropy in the morphological dynamics of phase transitions in liquid crystals.

1:39PM B31.00011 Liquid Crystal Switching Response by Localized Surface Plasmon Induced Electric Fields[1] , ZACHARY NUNO, LINDA HIRST, SAYANTANI GHOSH, School of Natural Sciences, University of California, Merced, CA 95343 USA — We investigate the effect of electric fields induced by localized surface plasmons (LSPs) from gold nanoparticles (AuNPs) on the director of a nematic liquid crystal (LC). We deposit LC thin films on a self-assembled AuNP layer and excite the LSPs in the AuNPs using 530 nm excitation light. Using polarized optical microscopy we follow the birefringence of the LC film as the excitation is turned on and off and observe the homeotropic alignment of the LC change to planar. This realignment response is observed to be dependent on the excitation wavelength, excitation power, and temperature; occurring only within 1 degree Celsius of the LC phase transition from nematic to isotropic.

1:51PM B31.00012 Tunable lithography masks using chiral nematic fluids , HYEON SU JEONG[1], Department of Chemical and Biomolecular Engineering, Korea Advanced Institute of Science and Technoogy, Daejon, Korea, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA, HEE-TAE JUNG, Department of Chemical and Biomolecular Engineering, Korea Advanced Institute of Science and Technoogy, Daejon, Korea — We present a facile route for pattern formation using chiral nematic fluids as tunable masks in lithography process. The chiral nematic phase prepared by adding a chiral dopant (CB15) to 5CB acted as a set of parallel cylindrical lenses and as a polarization selective photomask for the preparation of periodic line patterns. The pitch of the helical twist was easily controlled by the concentration of chiral agent and the feature size of the resulting pattern was easily tuned. Because of the high mobility of the small liquid crystalline compound, the preparation of chiral nematic fluids based lithography masks requires only a few seconds. This approach has significant advantages including facility, range of surface ordering, and rate of forming periodic arrays.

2:03PM B31.00013 Light sensitive liquid crystals: Focusing on surface and bulk transitions , PETR SHIBAEV, SETH BOURG, SHANNON ROSARIO, DANIEL BATEMAN, Fordham University, Department of Physics, ANDREY ILJIN, National Academy of Sciences of Ukraine — The study of transitions in liquid crystalline matrix resulting from light-induced conformational changes in newly synthesized light sensitive molecules are studied and discussed. Light sensitive molecules (novel chiral and non-chiral azo dyes, spiropyrans) were either embedded in a polymer film serving as a container for liquid crystals or dissolved in a bulk of liquid crystals. In both cases light-induced re-orientation of director was observed in nematic liquid crystals. In chiral liquid crystals the family of regular domains with a different helical pitch was formed. One of the most ordered representatives of this family was observed earlier in [1]. Interestingly, the shape and structural characteristics of the domains were different in liquid crystalline droplets and in the films contained between glass plates. It is possible to freeze the regular structure of the domains in highly viscoelastic liquid crystals and obtain free standing films. The role of viscosity is discussed and a simple theoretical model of observed effects is presented. The studied films can be used in photonic devices and also as detectors of environmental changes.

Session B32 DPOLY: Focus Session: Polymer Crystallization and Morphology 340 - Xinfei Yu, NIST

11:15AM B32.00001 Disentangled solid state and metastable polymer melt; a solvent free route to high-modulus high-strength tapes and films of UHMWPE[1]

, SANJAY RASTOGI[2], Loughborough University — Ultra High Molecular Weight Polyethylene (UHMWPE) having average molar mass greater than a million g/mol is an engineering polymer. Due to its light-weight, high abrasion resistance and biocompatibility it is used for demanding applications such as body armour, prostheses etc. At present, because of its high melt viscosity to achieve the uniaxial/biaxial properties in the form of fibers/films the polymer is processed via solution route where nearly 95wt% of the solvent is used to process 5wt% of the polymer. In past several attempts have been made to process the polymer without using any solvent. However, compared to the solvent processing route the achieved mechanical properties were rather poor. Here we show that by controlled synthesis it is feasible to obtain UHMWPE that could be processed free of solvent to make uniaxial tapes and biaxial films, having unprecedented mechanical properties, exceeding that of the solution spun fibers. We address some of the fundamental aspects of chemistry, physics, rheology and processing for the development of desired morphological features to achieve the ultimate mechanical properties in tapes and films. The paper will also address the metastable melt state obtained on melting of the disentangled crystals and its implication on rheology in linear and nonlinear viscoelastic region. Solid state NMR studies will be applied to establish disentangled state in solid state to the polymerisation conditions. 11:51AM B32.00002 A simple model for heterogeneous nucleation of isotactic polypropylene

, MICHAEL HOWARD, SCOTT MILNER, Penn State University — Flow-induced crystallization (FIC) is of interest because of its relevance to processes such as injection molding. It has been suggested that flow increases the homogeneous nucleation rate by reducing the melt state entropy. However, commercial polypropylene (iPP) exhibits quiescent nucleation rates that are much too high to be consistent with homogeneous nucleation in carefully purified samples. This suggests that heterogeneous nucleation is dominant for typical samples used in FIC experiments. We describe a simple model for heterogeneous nucleation of iPP, in terms of a cylindrical nucleus on a flat surface with the critical size and barrier set by the contact angle. Analysis of quiescent crystallization data with this model gives reasonable values for the contact angle. We have also employed atomistic simulations of iPP crystals to determine surface energies with vacuum and with Hamaker-matched substrates, and find values consistent with the contact angles inferred from heterogeneous nucleation experiments. In future work, these results combined with calculations from melt rheology of entropy reduction due to flow can be used to estimate the heterogeneous nucleation barrier reduction due to flow, and hence the increase in nucleation rate due to FIC for commecial iPP.

12:03PM B32.00003 Monte Carlo Simulations of Strain-induced Polymer Crystal Nucleation[1]

, WENBING HU, YIJING NIE, HUANHUAN GAO, Nanjing University, School of Chemistry and Chemical Engineering, State Key Lab of Coordination Chemistry — We performed dynamic Monte Carlo simulations of lattice polymer chains, to investigate primary crystal nucleation induced by a homogeneous stretching at high temperatures. We developed a new scheme to realize a homogeneous stretching of bulk polymer chains with their one chain ends fixed on a shifting plane and the other ends on a fixed plane. We observed a sudden decay of chain-folding probability in those newly emerged small crystallites, which indicated a transition of crystal nucleation from intramolecular mode to intermolecular mode. There exists a competition between two nucleation modes, as revealed by a theoretical fitting of the critical strains for mode transitions at various temperatures. The theoretical estimation is based on the classical nucleation theory.

12:15PM B32.00004 Solid to solid beta to alpha form transition in crystalline structures of syndiotactic polystyrene (sPS)

, TETSU OUCHI, SUGURU NAGASAKA, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The new solid to solid crystalline transition from beta to alpha forms in syndiotactic polystyrene (sPS) was discovered and analyzed. sPS has five crystalline structures: alpha, beta, gamma, delta, and epsilon forms. Among these crystalline structures, alpha and beta forms are two major crystalline structures due to their high mechanical properties. In this research, it was found that the transition was induced by mechanical strain well below the melting temperature of sPS (273 deg C) unlike the reverse transition from alpha to beta form observed at 260 deg C. The transition became more pronounced as testing temperature increased from 130 to 220 deg C. The transition should occur under the interaction of annealing process and mechanical strain, as the transition would not occur just by raising temperature. It was concluded from our experimental results that the destruction of the β form first took place under mechanical strain, causing beta form to transform into not only alpha form but also mesomorphic alpha form. The hot environment had a great impact on the perfection and the promptness of the transition: testing temperature could accelerate the transition ending up with more perfect alpha form transformed from beta form through mesomorphic alpha form.

12:27PM B32.00005 Molecular Structure of Semicrystalline Polyethylene Blends Studied by Broadband Coherent Anti-Stokes Raman Scattering Microscopy

, YOUNG JONG LEE, CHAD SNYDER, AARON FORSTER, MARCUS CICERONE, WEN-LI WU, National Institute of Standards and Technology — Blends of polyolefins have been widely used to diversify and improve material properties and to avoid complications that exist in blending immiscible heterogeneous polymers. The properties of a blend quite often deviate from predicted ones with the linear combination of its constituent homopolymers or copolymers, likely due to microscopic phase separation and differing degrees of crystallization. However, the current measurement techniques for studying the structure of polyolefin blends are primarily based on bulk averaging methods such as calorimetry or neutron scattering or through solvent extraction of a lower melting component. As a result, development of new blends depends on mostly empirical approached, not based on microscopic structural information. We demonstrate here that a noninvasive imaging technique, based on coherent anti-Stokes Raman Scattering (CARS) microscopy, can provide microscopic structural information of a bimodal polyethylene blend. We discuss new findings of the spatial distribution of species with different molecular architectures and the orientation of their semicrystalline structures.

12:39PM B32.00006 Enhanced segmental mobility of Poly(lactic acid) in presence of water

, OMKAR VYAVAHARE, SHAW HSU, University of Massachusetts Amherst — The objective of this work was to understand the effect of water on the segmental mobility of Poly(lactic acid) (PLA). When PLA was crystallized by soaking it in water, the crystallization temperature was lowered significantly, allowing PLA to crystallize even below the generally accepted glass transition temperature (T_g). PLA crystallized below 90^{o}C has a metastable α' crystalline phase. However, in presence of water, it formed a mixture of α', and stable α crystalline phases. Water also had a prominent effect on the physical aging of PLA, with the polymer rapidly undergoing densification in the glassy state compared to the dry conditions. Dielectric relaxation studies of PLA with 0% and 13% d-lactide content revealed contradictory influence of water on their respective sub-T_g (β) transitions. The β transition was suppressed for PLA with no d-lactide content, while it got enhanced for PLA with 13% d-lactide. These experiments demonstrate that water promotes interchain interactions and enhances segmental mobility. This allows the chains to have a conformation which provides an easier pathway with lower energy barrier for the transformation among various polymorphic states.

12:51PM B32.00007 Molecular engineering of high-performance elastomeric materials , SHENGWEI DENG, Department of Materials Science and Engineering, Johns Hopkins University, MICHAEL FALK, Departments of Materials Science and Engineering, Mechanical Engineering, Physics and Astronomy, Johns Hopkins University — Polyurethane is a typical elastomeric material and among the most versatile materials today. It is a linear block copolymer consisting of alternating soft and hard segments with phase separation due to thermodynamic segmental incompatibility. Inspired by the hierarchical structure of spider silk, this kind of block copolymer can be synthesized with two distinct blocks that can differ in their propensity to crystallize. Either the soft or hard segments can be amorphous or semicrystalline. Recent experiments indicate that crystallizable segments lead to higher tensile strength and that systems with crystalline hard segment exhibit better stiffness, strength and mechanical toughness. Here we implement molecular dynamics simulation to investigate the influence of block architectures on mechanical properties and molecular chain movement.

1:03PM B32.00008 Tuning Properties of Semi-Crystalline Polymers at Constant Crystallinity: Adjusting Rigid Amorphous Fraction and Crystallization Conditions by Solid-State Shear Pulverization , PHILIP BRUNNER, JOHN TORKELSON, Northwestern University — Semi-crystalline polymers consist of both crystalline and amorphous regions, the latter of which can be subdivided into rigid amorphous fraction (RAF) and mobile amorphous fraction. The RAF does not undergo a glass transition at the measured Tg but may remain rigid up to the melting temperature of the crystalline regions. This means that RAF can quantified by DSC measurements related to the change in heat capacity in going from the glassy to liquid state upon heating. We have discovered that RAF levels in some semi-crystalline polymers can be altered dramatically by solid-state shear pulverization although the crystallinity level remains constant. We take advantage of this to demonstrate how permeation characteristics and mechanical properties of semi-crystalline polymers may be significantly altered by SSSP while maintaining constant crystallinity levels. Examples include nylon 11 in which oxygen permeability can be decreased by 50% due to an increase in RAF, with the permeability reduction caused by nearly equal effects of RAF on solubility and diffusivity. Additionally, major changes in tensile properties of nylon 11 and polycaprolactone can be correlated with changes in RAF at constant crystallinity.

1:15PM B32.00009 Determining the Heat of Fusion and Crystallization Kinetics of Trogamid[1] , BIN MAO, PEGGY CEBE, Tufts University — Trogamid^{TM} is a high performance semi-crystalline polyamide with optical clarity, chemical resistance and high toughness. It also has much higher glass transition temperature than traditional polyamides, providing excellent thermal stability. We have used differential scanning calorimetry and real-time synchrotron wide and small angle X-ray scattering to study the isothermal crystallization of Trogamid from the melt at crystallization temperatures between $T_c = 221$ °C and 233 °C. Our goal is to correlate the endothermic area from heat flow measurements with the crystallinity index obtained from X-ray scattering, to provide fundamental thermal information about the heat of fusion of Trogamid, which has not been measured to date. Avrami analysis has also been performed over the same temperature range, and been correlated with spherulitic growth rate data obtained from polarizing optical microscopy. For isothermal melt crystallization, the Avrami exponent, n, ranged from 2.13 to 2.23 for T_c from 230 °C to 233 °C.

[1]The authors thank Professor Daniel Schmidt for providing Trogamid sample. Research was supported by the National Science Foundation through DMR-0602473; the MRI Program under DMR-0520655. X-ray work was conducted at the Brookhaven National Laboratory.

1:27PM B32.00010 Unusual Temperature Dependence of the Growth Rate of a Bromine Substituted Polyethylene , RUFINA G. ALAMO, WEI ZHANG, LAURA SANTONJA, Florida State University, FAMU-FSU College of Engineering, EMINE BOZ, KENNETH B. WAGENER, University of Florida, Department of Chemistry — Precisely halogenated polyethylenes are unique polyolefins with a halogen placed on and every "n" number of backbone carbons. Contrasting random analogs, precision systems are highly crystalline developing spherulitic morphologies due to a crystallization pattern similar to that of a homopolymer chain. The halogen is accommodated in the crystalline regions as a defect that strains the chain packing proportionally to the van der Waals radius of the halogen. In the present work, we have studied the temperature dependence of the linear growth rates of a bromine substituted polyethylene on each and every 21st backbone carbon. The linear growth rates display a discrete minimum with decreasing temperature at a crystallization temperature of 64.5 °C which is reminiscent of the minimum in crystallization rate observed in long chain n-alkanes. The spherulitic morphology and overall positive birefringence remains unchanged. The minimum in growth rate is analyzed on the basis of self-poisoning at the growth front resulting from frequent but unstable disordered chains depositions that accommodate the Br atoms.

1:39PM B32.00011 A Fast Scanning Calorimetric Comparison Study of Crystallization Behavior between Semi-crystalline Polymers and Liquid Crystals[1] , DONGSHAN ZHOU, JING JIANG, LAI WEI, ZHIJIE HUANG, GI XUE, Nanjing University — Mesomorphic state with similar liquid crystal order was found to precede the crystallization in many polymers, so the study of nucleation and crystallization from a liquid crystal can provide reference for the study of polymers. The same procedure to study the nucleation and crystallization of semi-crystalline polymers was used to study 4-cyano-4'-octyloxy biphenyl-carbonitrile (8OCB). Different from metastable semi-crystalline polymers of multi-folded chains, whose melting temperature was basically continuously dependent on the crystallization temperature, melting temperature of 8OCB should have definite values, corresponding to disordering of four different polymorphism modifications at 309.0 K, 319.0 K, 325.0 K, and 327.0K, respectively. But, a lower temperature melting peak below 300K was found when 8OCB was annealed at temperature below 250K. More importantly, the peak temperature shifted positively with the increasing annealing temperature, just the same as that of semi-crystalline polymers. At the moment, we were not sure about the structure of the metamorphism and why small molecular liquid crystal showed similar melting behavior that was thought only inherited to chain like semi-crystalline polymers.

1:51PM B32.00012 Unusual "Twisting" Morphology in Poly(3-hydroxybutyrate-co 3-hydroxyhexanoate) and Poly(bisphenol A hexane ether) Spherulites , JEROLD SCHULTZ, University of Delaware — Polarized light images of poly(3- hydroxybutyrate-co 3-hydroxyhexanoate) spherulites grown from the melt exhibit the standard evidence of periodic twisting of lamellae. AFM images of lamellae growing from the melt, on the other hand, reveal a sudden change in orientation and a trowel-like morphology. Similarly, AFM images of poly(bisphenol A hexane ether) (BA-C6) lamellae growing from the melt show a sudden orthogonal change of orientation. It is suggested that chain extension in the melt near the propagating front forces the observed reorientation, possibly through creation of crystals with an orientation approximately orthogonal to that of the original crystals. A rudimentary model for this behavior is proposed.

2:03PM B32.00013 Crystal Pattern and Orientation Structure of Poly Ethlyene Oxide at Surface[1] , QI LIAO, Institute of Chemistry, Chinese Academy of Sciences, Beijing (100190), China — We try to develop a new morphological method to estimate the orientation structure of polymer crystal at the surface quantitatively. The crystalline structures of PEO single crystals on PVPY substrates were studied in dependence on the degree of supercooling. We show that the diverse patterns could be explained by the difference of crystal orientation. The edge-on and flat-on structure, as well as the patterns in the cross-over states, could give the information of molecular structure.

Session B33 DPOLY DMP: Focus Session: Dielectric and Ferroelectric Polymers for Electrical Applications: Ferroelectrics 341 - Philip Taylor, Case Western Reserve University

11:15AM B33.00001 Phase Transitions as a Novel Mechanism for High-Speed Energy Storage[1]

, JERRY BERNHOLC, NC State University, Raleigh, NC 27695-7518 — In many energy applications there is an urgent need to store and quickly discharge large amounts of electrical energy. Since capacitors can be discharged far quicker than batteries and fuel cells, they have much higher power densities. At present, highly insulating polymers with large breakdown fields, such as polypropylene, are the dielectrics of choice in high-power capacitors. However, their energy densities are quite low because of small dielectric constants. Ferroelectric polymers from the PVDF family have significantly larger dielectric constants, yet their energy densities are still rather low. This can be traced to early saturation of their displacement fields with the applied electric field, and to somewhat lower breakdown fields. However, an admixture of a small amount of another polymer, such as CTFE, results in a dramatic increase in the stored energy [1]. We show that this highly non-linear increase in the energy density is due to the formation of disordered nanodomains with different copolymer concentrations, which undergo first-order non-polar to polar phase transitions with an increase of the applied field. The resulting energy density profile reproduces well the experimental data, while its variation with co-polymer concentration and distribution suggest avenues for additional substantial improvements in the stored energy [2]. Most recently, we have identified a low-activation-energy pathway for these successive phase transformations [3]. It provides further confirmation of the viability of the suggested energy storage mechanism and also enables fine-tuning of the kinetics of energy release by informed choices of suitable co-polymers.

11:51AM B33.00002 Constrained Molecular Dynamics Modeling of Dielectric Response in Polar Polyethylene Analogs and Poly(vinylidene flouride)[1]

, JEFFREY CALAME, Naval Research Laboratory, Washington, DC 20375 — A simplified molecular dynamics formalism for polymers, having united atoms with constrained bond lengths and bond angles along the backbone but allowing torsional motion, has been developed to model the dielectric response and ferroelectricity in polymers with permanent dipoles. Analytic relations existing on the backbone geometry and associated dihedral motion allow elimination of many dot and cross product evaluations. Also, constraint error correcting forces, symplectic integration with velocity prediction, random force excitation with damping and a momentum-conserving thermostat, and rapid neighbor list and long range force computation allow efficient computation and time steps as large as 20 fs to enable the study of relatively long time scale dielectric phenomena. Studies are performed on non-polar polyethylene for benchmarking, followed by a model system (polar polyethylene) which retains the molecular structure, dihedral potentials, and non-bonded interactions of polyethylene, except artificial partial charges are placed on the united atoms. The modeling is extended to poly(vinylidene fluoride) by changes to the molecular structure, potentials, and charges. Heterogeneous systems containing crystalline and amorphous arrangements of polymer chains are studied.

12:03PM B33.00003 Crystal Orientation and Temperature Effects on the Double Hysteresis Loop Behavior of a PVDF-*g*-PS Graft Copolymer[1]

, LEI ZHU, LIANYUN YANG, FANGXIAO GUAN, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OH 44106 — In a recent report, double hysteresis loop behavior is observed in a nanoconfined poly(vinylidene fluoride-*co*-trifluoroethylene-*co*-chlorotrifluoroethylene)-*graft*-polystyrene [P(VDF-TrFE-CTFE)-*g*-PS] copolymer. It is considered that the PS grafts are capable of reducing the compensation polarization and thus the polarization electric field during the reverse poling process, resulting in the double hysteresis loop behavior. In this study, we further investigated crystal orientation and temperature effects on this novel ferroelectric behavior. It is observed that with increasing the orientation factor, the electric displacement-electric field (D-E) loop changes from linear for non-oriented film to double loop for the well-oriented film. With increasing the temperature, the double hysteresis loop is gradually replaced by the single and open loop, which is attributed to the impurity ion migrational loss in the sample.

12:15PM B33.00004 Polarization Mapping in Ferroelectric Polymer Thin Films by Pyroelectric Scanning Microscopy

, JINGFENG SONG, STEPHEN DUCHARME, Department of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, Lincoln, Nebraska 68588-0299, USA — High-resolution mapping of polarization distribution in P(VDF-TrFE) Langmuir-Blodgett film was carried out through pyroelectric scanning microscopy with a focused 405nm blue diode laser beam. A lateral resolution of 500 nm was achieved by modulating the laser power at high frequency. At frequencies above 1 MHz, the laser spot size, rather than the thermal diffusion, becomes the limiting factor in the lateral resolution. The experimental results were compared to computer models developed with the finite element method.

12:27PM B33.00005 Interfacial polarization and internal electron tunneling effect on dielectric properties of multilayer polymer films

, JUNG-KAI TSENG, ZHENG ZHOU, MATT MACKEY, JOEL CARR, ERIC BAER, LEI ZHU, Case Western Reserve University — Due to large contrasts in dielectric constant and volumetric conductivity, Maxwell-Wagner-Sillars interfacial polarization is observed in poly(vinylidene fluoride) (PVDF) based multilayer films. This interfacial polarization is helpful to enhance the breakdown strength of multilayer films, because they serve as electron traps to prevent hot electron thermal runaway. In this study, the relationship between volumetric resistivity and internal electron tunneling in polysulfone (PSF)/(PVDF) multilayer film is reported. In general, resistivity decreases with decreasing the thickness of the insulating PSF layer. This is attributed to the internal electron tunneling in thin PSF layers. As a result, the electron-hole neutralization via the PSF layer decreases the interfacial polarization in the PVDF layer, resulting in a lower volumetric resistivity.

12:39PM B33.00006 Ab-initio study of high energy storage in polymers: PVDF-BTFE , RUI DONG, V. RANJAN, North Carolina State Univ., M. BUONGIORNO-NARDELLI, Univ. of North Texas and Oak Ridge National Laboratory, J. BERNHOLC, North Carolina State Univ. and Oak Ridge National Laboratory — Previous experiments [1] and our theoretical work [2] have indicated that introducing CTFE monomers in polyvinylidene fluoride (PVDF) in small concentration can lead to ultra high density capacitive energy storage. Our previous work indicates that this is due to (i) formations of domains with different impurity concentrations, and (ii) existence of a low energy barrier path connecting ground state non-polar phase to a polar phase. We are now investigating bromo-triflouroethylene (BTFE) in a PVDF-BTFE as a potential high energy density material. Our results show that PVDF-BTFE prefers the nonpolar phase up to a higher concentration of 33%, as compared to PVDF-CTFE(17%). This could lead to a higher proportion of PVDF sample being available for phase transition under the electric field. The calculated energy barriers for the electric-field-induced phase transition are also low and comparable to PVDF-CTFE. We will discuss the calculated phase equilibria and the potential of PVDF-BTFE for high density capacitive energy storage.

12:51PM B33.00007 Effect of crystal isomorphism on novel ferroelectric behaviors of P(VDF-TrFE)-based copolymers , LIANYUN YANG, Case Western Reserve University, XINYU LI, QIMING ZHANG, Pennsylvania State University, LEI ZHU, Case Western Reserve University — Novel ferroelectric behaviors of poly(vinylidene fluoride-*co*-trifluoroethylene) [P(VDF-TrFE)]-based copolymers, including relaxor ferroelectric and double hysteresis loop behaviors, have drawn great attention in research. Despite of a great amount of work have been done over the last two decades, the fundamental understanding of these behaviors is still lacking. In this work, the physics behind these novel ferroelectric behaviors are discussed based on the studies of P(VDF-TrFE)-based terpolymers and e-beam irradiated P(VDF-TrFE). We find that crystal isomorphism in P(VDF-TrFE)-based copolymers has a significant effect on the dielectric properties. This is achieved by pinning the polymer chains with structural defects. Consequently, nanodomains and easy dipole switching are responsible for the novel ferroelectric behaviors. This understanding will help us to further design new polymers with better dielectric/ferroelectric properties.

1:03PM B33.00008 Ferroelectric Polymer Composite with Enhanced Breakdown Strength , KUO HAN, MATTHEW GADINSKI, QING WANG, Department of Materials Science and Engineering, The Pennsylvania State University, Univeristy Park — Numerous efforts have been made in the past decades to improve the energy storage capability of dielectric capacitors by incorporating ceramic addictives into polymers. Ferroelectric polymers have been particularly interesting as matrix for dielectric composites because of their highest dielectric permittivity and energy density. However, most polymer composites suffer from significantly reduced breakdown strength, which compromises the potential gain in energy density. In this work, various metallic alkoxide were introduced into the functionalized ferroelectric poly(vinylidene fluoride-*co*- chlorotrifluoroethylene), P(VDF-CTFE), via covalent bonding. The composite with the optimized composition exhibited the Weibull statistical breakdown strength of 504.8 MV/m, 67.6 % higher than the pristine polymer. The enhanced breakdown strength was mainly ascribed to the cross-linking and the formation of deep traps, which effectively reduced the conduction and further lowered the energy loss. Additionally, the homogeneous dispersion of the inorganic phase and the small contrast in permittivity between the polymer and amorphous oxides also contribute to the improved dielectric strength. The dielectric spectra of the composites have been recorded at varied temperatures and frequencies, which revealed the presence of the interfacial polarization layer in the composites.

1:15PM B33.00009 Effect of Polymer Blocking Layer and Processing Method on the Breakdown Strength and the Extractable Energy Density of Barium Titanate/poly(vinylidene fluoride-co-hexafluoropropylene) Nanocomposite Thin Film Capacitors , YUNSANG KIM, MOHANALINGAM KATHAPERUMAL, O'NEIL SMITH, Georgia Tech, MING-JEN PAN, Naval Research Laboratory, JOSEPH PERRY, Georgia Tech — Polymer-metal oxide nanocomposites are of great interest because of their high energy density and easy processability, which make them candidate materials for energy storage applications. Although loading of high-k filler in polymer matrix is desirable to maximize energy density of nanocomposites, the decrease of breakdown strength at higher loading compromises a potential gain in energy density. In this work, we investigate the effect of a fluoropolymer (CYTOP) blocking layer in $BaTiO_3$/poly(vinylidene fluoride-co-hexafluoro propylene) nanocomposite films on the improvement of breakdown strength and energy storage density. The introduction of blocking layer may serve to prevent moisture absorption and charge injection from electrode, thereby decreasing the probability of catastrophic breakdown events. We also examine the influence of processing method, i.e. spin- or blade-casting, on the performance of bilayer films. The charge-discharge method shows about a twofold increase in extractable energy density (from 2 to 3.7 J/cm^3) of bilayer films fabricated by blade-casting compared to single layer film by spin-casting because of improved breakdown strength. The results will be discussed in regards to morphology, electric field distribution, and loss of bilayer films.

1:27PM B33.00010 Relaxor Ferroelectric Behavior in Poly(vinylidene fluoride-co-bromotrifluoroethyene) , MATTHEW GADINSKI, Wang Research Group- The Pennsylvania State University, QING WANG, Pennsylvania State University — Copolymers of vinylidene fluoride (VDF) and bromotrifluoroethylene (BTFE) were prepared over a composition range up to the disappearance of crystallinity ($\sim$ 9 mol % BTFE). The resulting copolymers were characterized by ^{19}F NMR to elucidate composition and quantify the linkage defects of the polymer chain. Chain conformations were analyzed by FTIR analysis and crystal structures were studied by DSC and WAXD. The dielectric properties were evaluated by dielectric spectroscopy as a function of frequency and temperature and at high fields to investigate the influence of BTFE on dielectric behavior. The results indicate that the P(VDF-BTFE) copolymers exhibit relaxor ferroelectric behavior similar to those reported in PVDF terpolymers resulting from a mixed α/γ crystalline phase. Effects of processing such as stretching and crosslinking have also been studied with respect to the relaxor ferroelectric properties of the copolymers. Stretching was found to improve the breakdown strength of the films along with enhancing both the stored and discharged energy density. Preliminary crosslinking results indicate that stretched and cross-linked polymer show a reduced remnant polarization.

1:39PM B33.00011 BaTiO3 and polypropylene nanocomposites for capacitor applications , DAXUAN DONG, LONGXIANG TANG, LEI ZHU, Case Western Reserve Unviersity, JE KYUN LEE, Agiltron, Inc, CASE WESTERN RESERVE UNIVERSITY COLLABORATION, AGILTRON, INC COLLABORATION — A novel strategy to uniformly disperse 70-nm BaTiO3 ferroelectric nanoparticles in a dielectric polypropylene (PP) matrix is developed in order to achieve high dielectric constant and high energy density for capacitor applications. By modifying BaTiO3 surface with a bis-phosphonic acid-terminated polyhedral oligomeric selsisquioxane (POSS), a nanocomposite with BaTiO3@POSS uniformly dispersed in PP matrix was achieved. The nanocomposite film containing a high nanoparticle content of 30 vol.% exhibited a high dielectric constant of 32 and a breakdown voltage of 220 MV/m, but with a high energy loss. Improvement of this nanocomposite by understanding the interfacial polarization is carried out in this work. The dielectric constant difference between BaTiO3 and PP can generate interfacial polarization and subsequent internal conduction in BaTiO3 particles upon bipolar polarization. Reduction of this internal conduction mechanism will significantly reduce the hysteresis loss in polymer nanodielectrics.

1:51PM B33.00012 Dielectric Bilayer Films Comprising Polar Cyanolated Silica Sol-Gel and Nanoscale Blocking Layer for Energy Storage Applications , MOHANALINGAM KATHAPERUMAL, YUNSANG KIM, O'NEIL SMITH, School of Chem and Biochem, Georgia Inst Tech, AMIR DINDAR, CANEK FUENTES-HERNANDEZ, DO-KYUNG HWANG, School of Electrical and Computer Engineering, Georgia Inst Tech, MING-JEN PAN, Naval Research Laboratory, BERNARD KIPPELEN, School of Electrical and Computer Engineering, Georgia Inst Tech, JOSEPH PERRY, School of Chem and Biochem, Georgia Inst Tech — Organic-inorganic hybrid sol-gel containing polar groups, which can undergo orientational polarization under the influence of an electric field, provide a potential route to processable and rational design of materials for energy storage applications. However, the porous nature of sol-gel films, which significantly lowers breakdown strength, limits the potential of this material for energy storage particularly in high-field applications. In this work, we fabricate and characterize dielectric bilayer films comprising cyanolated silica sol-gel film prepared from 2-cyanoethyltrimethoxysilane (CNETMS) precursor and nanoscale blocking layers, which include amorphous fluoropolymer, SiO_2, Al_2O_3 and ZrO_2 deposited by spin casting, electron beam evaporation or atomic layer deposition (ALD). CNETMS films with 50 nm ZrO_2 blocking layer exhibit an extractable energy density of 13 J/cm^3, which is about a twofold enhancement compared to CNETMS films without blocking layer. The effect of the blocking layer will be discussed in terms of surface morphology, dielectric contrast, i.e. the ratio of relative permittivity between oxide layer and sol-gel film, electric field distribution, breakdown strength and statistics, bias polarity, and loss of the bilayer films.

2:03PM B33.00013 A variational formulation of electrostatics for heterogeneous dielectric media[1] , FRANCISCO SOLIS, Mathematical and Natural Sciences, Arizona State University, VIKRAM JADHAO, MONICA OLVERA DE LA CRUZ, Materials Science and Engineering, Northwestern University — Many biological and synthetic soft matter systems involve fixed or mobile charges. The electrostatic interactions between these charges often play crucial roles in determining the structural properties and physical behavior of these systems. Coarse-graining of the properties of these systems often leads to consideration of free charges embedded in a medium with varying dielectric permittivities. Investigation of the behavior of these systems by theoretical or computational methods requires, therefore, formulations of their electrostatic properties that suitably address the properties of the medium. In this talk we present a new and powerful variational formulation of the electrostatics of charged particles in heterogenous media. Our formulation replaces the electric and polarization vector fields for the induced polarization charge density at interfaces. In addition, this variational principle has the property of evaluating to the true free energy of the system at its minimum; a property not found in many other variational formulations. We discuss the application of this functional to a variety of electrostatic problems and show how it allows the development of new algorithms for simulation of charged systems in heterogeneous media.

Session B34 DPOLY: Focus Session: Dynamics of Glassy Polymers Under Nanoscale Confinement 342 - Zahra Fakhraai, University of Pennsylvania

11:15AM B34.00001 Self-Diffusion of Poly(isobutyl methacrylate) in Thin Films , JOSHUA KATZENSTEIN, DUSTIN JANES, HALEY HOCKER, JUSTIN CHANDLER, CHRISTOPHER ELLISON, The University of Texas at Austin — While relevant to a variety of applications, such as nanocomposite intercalation and molecular transfer printing, the diffusion of polymers parallel to their confining interfaces has received limited experimental attention to date. A refinement of fluorescence recovery after patterned photobleaching (FRAPP) has been developed by our group as a versatile platform for understanding nanoconfined diffusion. Poly(isobutyl methacrylate) (PiBMA) is an ideal candidate for these studies because (in quartz or silicon wafer supported thin films) it exhibits a film thickness independent glass transition temperature (Tg). This is important because, according to the Rouse model, the diffusion coefficient does not depend simply on the absolute temperature, but on the distance from Tg. Therefore, in our systems the origin of the diffusion coefficient is possibly decoupled from Tg changes that are present in other polymer systems. In this talk, the effect of a variety of parameters, such as film thickness, diffusion temperature, and confining interfaces, will be discussed.

11:27AM B34.00002 Viscosity of poly(methylmethacrylate) films on silicon[1] , OPHELIA K. TSUI, RANXING N. LI, Department of Physics and Materials Science and Engineering Division, Boston University, DONGDONG PENG, Boston University — Previously we showed that the viscosity of polystyrene films on silicon decreased noticeably with decreasing film thickness when the film thickness was decreased below about 10 nm. Moreover, the result could be explained by using a two-layer model presuming a hydrodynamic coupling between a mobile interfacial layer, located at the top, and the remaining, bulk-like layer underneath it. In this experiment, we study the viscosity of poly(methylmethacrylate) (PMMA) films supported by silicon. Contrary to the result found of the polystyrene films, the viscosity of the PMMA films increases with decreasing film thickness. The two-layer model still applies, but the interfacial layer has to be assumed to be slow and located at the substrate interface, beneath the bulk-like layer.

11:39AM B34.00003 Relaxation of wrinkles: A new viscoelastic metrology[1] , KAMIL TOGA, NARAYANAN MENON, THOMAS RUSSELL, University of Massachusetts, Amherst — The relaxation of a wrinkle pattern can be exploited as a viscoelastic metrology. We used spin-coated polystyrene (PS) films (thickness ranging from 69 to 299 nm) that were floated on the surface of water. Viscoelastic behavior is introduced to the film by depressing the glass transition of PS with a soluble plasticizer, dioctyl phthalate. Wrinkle patterns are formed by placing a small droplet (1μL) at the center of the floating disc. Due to the differential tension generated across the film, radial wrinkles form around the drop where the compressive axial force buckles the membrane. Thereafter, length of the wrinkles decays, and so does their wavelength. Stress and strain exerted by the droplet can be measured as a function of the size of the wrinkles. Hence, extensional slow-rate-viscosity is calculable. We have studied the relaxation of wrinkles as a function of confinement and plasticizer content. Unusual dynamic behavior due to confinement was observed.

11:51AM B34.00004 Probing nano-rheology in thin polymer films , KARI DALNOKI-VERESS, Physics and Astronomy, McMaster University — In this talk I will summarize our recent work on using stepped films to uncover some of the physics relevant to polymer rheology on length scales comparable to the size of polymer molecules. The work presented will focus on the efforts of a larger collaboration (Elie Raphael's theory group in Paris and James Forrest's group in Waterloo). The simple geometry of a polymer film on a substrate with a step at the free surface is unfavourable due to the excess interface induced by the step. Laplace pressure will drive flow within the film which can be studied with optical and atomic force microscopies. Because of the excellent agreement between theory and experiment when we probe "bulk-like" properties, these studies provide an opportunity to study how such systems transition from the bulk to confined. Starting with some of the results of levelling experiments on simple stepped films as well as the levelling of polymer droplets on thin films, I will finish with a discussion on our more recent efforts to elucidate confinement effects.

12:27PM B34.00005 Structural relaxation of thin polymer films[1]

, BRADLEY FRIEBERG, EMMANOUIL GLYNOS, University of Michigan, GEORGIOS SAKELLARIOU, University of Athens, PETER GREEN, University of Michigan — Time-dependent structural relaxations, physical aging, of films with thicknesses in the range of 50 nm to 2 microns, of star-shaped polystyrene (SPS) macromolecules are dependent on film thickness, H. In contrast to linear chain PS (LPS) where the aging rate, R, is independent of molecular weight, M, R is dependent on the functionality, f, and on the molecular weight per arm, Marm for SPS macromolecules. For example, the aging rates decreased 15 percent, for f of 8, and 40 percent, for f of 16, in comparison to that of linear chains, for a given film thickness. The aging rates, R, of the SPS macromolecules moreover are appreciably slower than their linear chain analogs, for a given H. The aging rates of the linear chain and star-shaped polymer films may be reconciled in terms of a model that accounts for changes in the local glass transition of the polymer films as a function of distance from an interface.

12:39PM B34.00006 Capillary-driven flow as a probe of enhanced surface mobility in glassy polymer films

, YU CHAI, University of Waterloo, Waterloo, On, Canada N2L 3G1, THOMAS SALEZ, Laboratoire de Physico-Chimie Théorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, JOSHUA D. MCGRAW, McMaster University, 1280 Main St. W, Hamilton, ON, Canada, L8S 4M1, ELIE RAPHAEL, Laboratoire de Physico-Chimie Théorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, JAMES A. FORREST, University of Waterloo, Waterloo, On, Canada N2L 3G1 — We present the use of a novel experimental arrangement [*McGraw et al. Soft Matter* **7**, *7832 (2011)]* to directly distinguish the dynamical behavior and heterogeneity of polymer thin films above and below the glass transition temperature T_g. In particular, by monitoring the capillary-driven evolution of a stepped thin polystyrene film over a temperature range encompassing the bulk T_g value, we find evidence suggesting enhanced surface mobility. Furthermore, by varying the initial aspect ratio of the sample we can examine the heterogeneity of the sample dynamics. The results of these experiments above T_g are consistent with homogenous viscous flow [*McGraw et al. PRL* **109**, *128303 (2012)],* whereas those below T_g indicate a localization of the flow over a thin surface layer only. We thus develop a linear thin film equation for superficial viscous flows, which is analogous to the surface diffusion model, and for which exact analytical solutions are known and in good agreement with the present experimental data.

12:51PM B34.00007 Convergence to Self-Similar Regimes in Thin Polymer Films

, MICHAEL BENZAQUEN, THOMAS SALEZ, ELIE RAPHAËL, ESPCI, ELIE RAPHAËL TEAM[1], KARI DALNOKI-VERESS TEAM[2] — The surface of a thin liquid film with nonconstant curvature is unstable, as the Laplace pressure drives a flow mediated by viscosity. Recent experiments and theory applied to stepped polymer films have shown excellent agreement and provide a technique for the study of polymer confinement, the glass transition, and slip at the fluid substrate interface to name a few [1]. The thin film equation governs the evolution of the free surface profile in the lubrication approximation. Despite many efforts, this equation remains only partially solved. We present an analytical and numerical study of the thin film equation. Linearising this equation enables us to derive the Green's function of the problem and therefore obtain a complete set of solutions. We show that the solutions of the problem with equilibrium boundary conditions uniformly converge in time towards a first kind self-similar universal attractor. A numerical study enables us to extend our results to the nonlinear thin film equation.

1:03PM B34.00008 The Onset of Plasticity in thin Polymer Films

, BEKELE J. GURMESSA, ANDREW B. CROLL, North Dakota State University — Polymers are widely used materials because of their numerous advantageous mechanical properties, for example their high degree of toughness. Despite the fundamental importance of the onset of plastic deformation to many material processes, it is still relatively poorly defined in the literature. Here we employ a carefully designed experimental method in order to evaluate the point of onset of plasticity in thin, glassy polystyrene films. Essentially we utilize the residual stress caused by local bending in the thin film. We show that plastic failure is initiated at extremely low strains, of order 0.1% for polystyrene. Not only is this critical strain small in comparison to bulk measurement, we also show that it is influenced by thin film confinement - leading to an increase in the critical strain for plastic failure as film thickness approaches zero. Finally, the same experimental method is used to investigate the response of confined block copolymer thin films in the ordered and disordered state.

1:15PM B34.00009 Competitive effects in the dynamics of confined ultra-thin polymer films[1]

, CHRYSOSTOMOS BATISTAKIS, ALEXEY LYULIN, THIJS MICHELS, Eindhoven University of Technology — Fillers, as carbon black or silica, are widely used in polymer systems to improve mechanical properties. In high volume fractions, these fillers connect to each other through polymeric bridges and they create a percolation network inside the polymer matrix. The rigidity of this network depends on the filler volume fraction and is rapidly breaking down under loading. The scope of this work is to understand the polymer dynamical behavior of the interparticle polymeric bridges. For that purpose we have performed molecular-dynamics (MD) simulations on coarse-grained polymer films which are confined between two crystalline Lennard-Jones substrates for different substrate-substrate separations. Various polymer-substrate attraction strengths have been chosen. The polymer structure and segmental dynamics in different film layers has been analyzed. We found that increasing attraction strength leads to deceleration of the film dynamics due to a slowing down close to the substrates, but decrease of film thickness leads to an acceleration of these dynamics. We attribute this acceleration to finite-size scaling effects. For thick films an acceleration of dynamics in the middle takes place for sufficiently high attraction strengths due to the effective increase of the glassy layers thicknesses

1:27PM B34.00010 Insight into Polymer De-wetting: A Neutron Reflectivity Study of Three-Arm Polystyrene Stars in Polystyrene Thin films[1]

, THUSITHA ETAMPAWALA, NAMPUENG PANGPAIBOON[2], DVORA PERAHIA, Clemson University, CANDICE HALBERT, JIM BROWNING, SNS, Oak Ridge National Laboratory, NISANART TRAIPHOL, Research Unit of Advanced Ceramics, Department of Materials Science Faculty of Science, Chulalongkorn University, Bangkok , Thailand, RAKCHART TRAIPHOL, Laboratory of Advanced Polymers and Nanomaterials, Department of Chemistry, Faculty of Science, Naresuan University, Phitsanulok, Thailand — While polymeric coatings are ubiquitous, de-wetting remains a challenge. As both enthalpic and entropic contributions often affect the de-wetting process, small changes either compositional or in processing conditions are sufficient to impact the stability of thin films. We have recently shown that blending small amounts of three-arm polystyrene (PS) star polymers are sufficient to inhibit de-wetting of thin polystyrene thin films. The role of the three-arm star has been investigated using neutron reflectometry. We have followed the distribution of the three-arm PS stars in a thin film of d-PS as function of time as the temperature was raised above Tg of the PS. Films of d-PS/h-three-arm star PS were cast from toluene and the polymer profiles were determined as a function of time as the temperature was varied. The result show a clear migration of the three-arm stars to both interfaces, enhancing the number of chain ends at the interface. As the molecular weights of the star arm increases, it migrates slower to the interface.

1:39PM B34.00011 Effects of Solvents on Confinement of Conjugated Polymer into Soft Nanoparticle[1]

, NARESH OSTI, THUSITHA ETAMPAWALA, UMESH SHRESTHA, SIDATH WIJESINGHE, DVORA PERAHIA, Clemson University — Conjugated polymers when collapsed into nano dimension form soft nanoparticles (poly-dots) without losing their electro-optical characteristics. The brightness together with the bio-compatibility of these nanoparticles has shown significant potential in intracellular fluorescence imaging as well as building blocks for light harvesting devices. The conformations of the polymers in the poly-dots are a key to their stability and optical properties. The current work investigates the structure and stability of poly-dots of *di-alkyl para polyphenyleneethynylene* (PPE) conjugated polymers in ethylene glycol and in water. Small angle neutron scattering (SANS) studies have shown that PPEs form spherical fuzzy poly-dots both in water and in ethylene glycol. In water, the poly-dots remain fairly stable up to a temperature of 80^0C. In ethylene glycol however the poly-dots swell with increasing temperature. The structure of the confined structure obtained from SANS is compared with fluorescence spectroscopy results where the intensity of the fluorescence is inversely proportional to the degree of confinement.

1:51PM B34.00012 Probe of Dynamic Heterogeneity in Freeze-dried Polymer with similarities to thin film

, JIE XU, CHAO TENG, GI XUE, Department of Polymer Science and Engineering, Nanjing University — Understanding the dynamics of polymer chains in confined states is still crucial in the field of soft condensed matter. Dynamic heterogeneity is widespread in the confined system and could strongly alter the overall dynamics, such as in the experimental case of a free surface or a held fixed region. In this work, we show the dynamic heterogeneity in the freeze-dried polystyrene system through a combination of fluorescence nonradiative energy transfer (NRET) method, TMA, and PALS. The NRET data shows that the interchain distance could be altered by other the primitive solution concentration of the freeze-dried PS or the thickness of the free-standing film. Striking similarity of interchain packing density effect on the Tg is find the freeze-dried systems and free-standing films. The application of stress can also make a glass flow. We applied a uniaxial stress on the freeze-dried PS, a shear-induced flow is curried in the region with reduced interchain packing density. The polymer chains in this region show increased segmental mobility, which prompts the shear-induced solid-to-fluid transition to happen well below the bulk glass transition temperature.

2:03PM B34.00013 Entanglement Density Changes in Free-Standing Thin Polymer Films

, JOSEPH STANZIONE, RICHARD WOOL, University of Delaware — The entanglement molecular weight M_e is obtained when a random walk chain crosses a plane three times to form a loop (R.P. Wool '83) such that for polymers with structure $-CH_2$-CHX- where X is the side group, it is found that $M_e = 31\ C_\infty\ M_o/j$, where C_∞ is the characteristic ratio, M_o is the monomer mol weight and j=2 is the number of bonds per monomer. In thin films of thickness $d < 2R_g$, M_e behaves as $M_e \sim d$ and this behavior is confirmed by computer simulation of random walks in thin films with reflecting boundary conditions. Thus, the entanglement density $v \sim 1/M_e$ increases as d decreases and rheological properties such as plateau modulus change as $G_{N^o} \sim 1/d$ and plateau creep compliance $J_o \sim d$. The mechanical stiffening of thin films is in accord with recent experiments of McKenna et al (2012). The results are also in accord with the Packing model (Lin, Kavassil, Fetters 1983) where $M_e = 354\ p^3$ in which $p = M_o\ j/[C_\infty\ b_o^2]$. The packing model is exactly derived from the Wool entanglement model for these polymers since $C_\infty = 1.36\ [M_o/j]^{1/2}$. The empirical packing model with its excellent data correlation $M_e \sim p^3$ has been misinterpreted by many and such suggestions that v decreases due to nanoconfinement and $G_{N^o} \sim d$ are incorrect.

11:15AM B35.00001 Magnetic excitations in the high-T_c superconductor $HgBa_2CuO_{4+d}$ at low doping[1]

, CHELSEY DOROW, M.K. CHAN, Y. TANG, G. YU, University of Minnesota, YUAN LI, Max Planck Institute for Solid State Research, Germany, N. BARISIC, University of Minnesota, J. PARK, O. SOBOLEV, A. TEICHERT, Forschungsneutronenquelle Heinz Maier-Leibnitz, Germany, Y. SIDIS, Laboratoire Leon Brillouin, France, P. STEFFENS, Institut Laue Langevin, France, D. ABERNATHY, Oak Ridge National Lab, X. ZHAO, University of Minnesota, Jilin University, China, P. BOURGES, Laboratoire Leon Brillouin, France, M. GREVEN, University of Minnesota — We report on the observation of magnetic excitations in the very underdoped regime of the high-T_c superconductor $HgBa_2CuO_{4+d}$ (Hg1201). Our previous inelastic neutron scattering measurements of optimally doped ($T_c \approx 95$ K) and moderately underdoped ($T_c \approx 65$ K) samples revealed two novel, weakly-dispersive magnetic excitation branches below the pseudogap temperature T* [Y. Li et al., Nature 468, 283 (2010); Y. Li et al., Nature Phys. 8, 404 (2012)]. These excitations are associated with the translational symmetry preserving magnetic order previously established to be a universal property of the pseudogap phase [B. Fauqué et al., Phys. Rev. Lett. 96, 197001 (2006); Y. Li et al., Nature 455, 372 (2008); Y. Li et al. Phys. Rev. B 84, 224508 (2011)]. In $YBa_2Cu_3O_{6+d}$, the strength of this order was found to decrease in very underdoped samples [V. Balédent et al. Phys. Rev. B 83, 104504 (2011)]. Indeed, we find no evidence of pseudogap excitations in very underdoped Hg1201 ($T_c = 45$ K), and instead we observe strong antiferromagnetic fluctuations over a large energy range (10 -150 meV).

[1]Work supported by DOE-BES.

11:27AM B35.00002 Unusual form factor of the novel pseudogap excitations in $HgBa_2CuO_{4+\delta}$

, MUN CHAN, C. DOROW, Y. TANG, G. YU, M. GREVEN, University of Minnesota, N. BARISIC, CEA,Saclay, Y. LI, Peking University, K. HRADIL, R. MOLE, Forschungsneutronenquelle Heinz Maier-Leibnitz, Germany, P. STEFFENS, Institut Laue Langevin, France, X. ZHAO, Jilin University, Y. SIDIS, P. BOURGES, Laboratoire Léon Brillouin, France — Following the discovery of a universal novel magnetic order in the pseudogap phase of the cuprates [B. Fauqué et al. PRL 96, 197001 (2006); Y. Li et al., Nature 455, 372 (2008)], our inelastic neutron scattering measurements of HgBa2CuO4+δ (Hg1201) revealed two weakly-dispersive excitation branches associated with this ordered state [Y. Li et al., Nature 468, 283 (2010); Y. Li et al., Nature Phys. 8, 404 (2012).]. The dependences of the mode intensities on the momentum transfer Q = (HKL) (r.l.u.) are inconsistent with traditional magnetic or structural form factors. The intensity of the high-energy mode is zero when Q is parallel to the copper-oxygen planes (i.e., for L=0), peaks at L = 8 (r.l.u.), and decreases again at large L. We observe the opposite behaviour for the low- energy mode, which is strongest when L=0. In combination with polarized inelastic neutron scattering results, this indicates possible dual magnetic and structural characteristics of the novel excitations. Work supported by DOE-BES.

11:39AM B35.00003 Polarised neutron study of the "even" and "odd" magnetic excitations in $YBa_2Cu_3O_{6.9}$, CHRISTOPHER LESTER, STEPHEN HAYDEN, University of Bristol, JIRI KULDA, Institut Laue-Langevin, DAVID CARDWELL, NADENDLA HARI BABU, University of Cambridge — On cooling through T_c, the spin excitation spectra of cuprate superconductors becomes dominated by the neutron spin resonance (NSR), a collective mode centred at $\mathbf{Q}_{AF}$. We have used polarized inelastic neutron scattering to measure the spin excitations of $YBa_2Cu_3O_{6.9}$ (T_c =93 K), unequivocally confirming the magnetic character of the NSR in both the odd and even channels. In the odd channel, the NSR is anisotropic in spin space, that is the out of plane (c) component of $\chi''(\mathbf{Q},\omega)$ is approximately 1.4 times larger than the in-plane (a/b) component. Conversely, the much weaker even channel resonance is isotropic to within experimental error, and the low energy response maintains a large gap (below ∼30 meV) in the normal state. While it is generally accepted that the NSR is ubiquitous in at least the hole-doped cuprates, recently two further collective modes have been observed in $HgBa_2CuO_{4+\delta}$. If these weakly-dispersive "Ising-like" modes were also universally present, then they might radically alter our view of the cuprate superconducting state. However, we find no evidence of this type of excitation in $YBa_2Cu_3O_{6.9}$, suggesting that these modes may in fact be unique to certain systems.

11:51AM B35.00004 Effective J_1-J_2 model for the spin wave in the superconducting $(Tl,Rb)_2Fe_4Se_5$, SONGXUE CHI, FENG YE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, WEI BAO, Department of Physics, Renmin University of China, Beijing, 100872, China, ANDREI T. SAVICI, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, MATTHEW B. STONE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, RANDY S. FISHMAN, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, H.D. WANG, C.H. DONG, MINGHU FANG, Department of Physics, Zhejiang University, Hangzhou 310027, China — Spin wave excitations in the superconducting state of $(Tl,Rb)_2Fe_4Se_5$ were determined by inelastic neutron scattering measurements. Four doubly degenerate spin wave branches, one gapped acoustic and 3 optical, span an energy range of about 210 meV. The spin wave spectra were successfully described by a J_1-J_2 Heisenberg model which includes the in-plane nearest (J_1 and J_1'), next nearest neighbor (J_2 and J_2') interactions within and between the 4-spin blocks, inter-plane interaction (J_c) and a single-ion anisotropy. The exchange coupling constants obtained indicate that the spin block order verges on a noncollinear in-plane-spin phase observed in $Tl_2Fe_4Se_5$.

12:03PM B35.00005 Anisotropy of the Superconducting State in Sr_2RuO_4[1] , M.R. ESKILDSEN, C. RASTOVSKI, University of Notre Dame, IN, USA, W.J. GANNON, Northwestern University, IL, USA, C.D. DEWHURST, Institut Laue-Langevin, France, D. PEETS, H. TAKATSU, Y. MAENO, Kyoto University, Japan — Multiple experimental and theoretical studies provide compelling support for triplet pairing of electrons and an odd, p-wave order parameter symmetry in superconducting Sr_2RuO_4. However, seemingly contradictory experimental results have left important questions concerning the detailed structure and coupling of the orbital and spin parts of the order parameter in this compound unresolved. We have used small-angle neutron scattering to study the vortex lattice in Sr_2RuO_4 in order to measure the intrinsic anisotropy (Γ_{ac}) of the superconducting state between the the c axis and the RuO basal plane. Up to fields of 1.2 T and temperature of 800 mK, we found no variation of $\Gamma_{ac} \approx 60$. This is consistent with the Fermi velocity anisotropy on the β Fermi-surface sheet, but greatly exceeds the upper critical field anisotropy $H_{c2}^{\perp c}/H_{c2}^{\parallel c} = 20$. This result poses significant constraints on the possible order parameter symmetry in Sr_2RuO_4.

12:15PM B35.00006 Bulk Magnetization in the Superconducting State of UPt_3[1] , WILLIAM GANNON, WILLIAM HALPERIN, Northwestern University, Department of Physics and Astronomy, USA, CATHERINE RASTOVSKI, MORTEN ESKILDSEN, University of Notre Dame, Department of Physics, USA, PENGCHENG DAI, University of Tennessee, Department of Physics and Astronomy, USA, ANNE STUNAULT, Institut Max von Laue-Paul Langevin, France — The unconventional superconductor UPt_3 has long been thought to have an odd parity orbital, and triplet spin state. An important signature of such a state is the temperature independence of the spin susceptibility across the superconducting transition temperature. Here, we report bulk measurements of the susceptibility of UPt_3 for magnetic fields along the crystal a-axis performed with polarized neutron diffraction. Temperature independence at all magnetic fields is observed, suggesting a spin triplet superconducting state for the entirety of the phase diagram, with equal spin pairs in the crystal basal plane. These results will be discussed in the context of existing theories for the superconducting state of this paradigm heavy fermion material [Graf et. al., PRB 62, 14393; Tsutsumi et. al., JPSJ 81, 074717 (2012)].

[1]Support from US Department of Energy, Basic Energy Science, Division of Materials Science and Engineering awards DE-FG02-05ER46248, DE-FG02-10ER46783, and DE-FG02-05ER46202

12:27PM B35.00007 Kerr effect studies of the heavy fermion superconductor URu_2Si_2[1] , ELIZABETH SCHEMM, Department of Physics, Stanford University, HOVNATAN KARAPETYAN, Department of Applied Physics, Stanford University, ERIC BAUER, Los Alamos National Laboratory, AHARON KAPITULNIK, Department of Physics and Department of Applied Physics, Stanford University — In the heavy fermion metal URu_2Si_2, the very large entropy carried by the 5f electrons is released at ~ 17.5 K via a second-order phase transition to a "hidden order" state. Below ~ 1.5 K superconductivity emerges with an as-yet unknown gap structure, adding to the mystery associated with this material. In this talk we present polar Kerr effect (PKE) measurements of URu_2Si_2 crystals using a Sagnac interferometer. PKE is sensitive to time-reversal symmetry (TRS) breaking since it measures the existence of an antisymmetric contribution to the real and imaginary parts of the frequency-dependent dielectric tensor. Such a contribution is necessarily absent if TRS is not broken in the material. We find a weak magnetic signal in the hidden order phase that seems to not influence superconductivity. The presence of a finite Kerr signal below T_c provides strong evidence that time reversal symmetry is broken in the superconducting state. The relationship between the magnetic response in the hidden order phase and superconductivity is also studied. We further compare our results to other unconventional superconductors.

12:39PM B35.00008 High resolution ^{17}O Knight shift measurements of $HgBa_2CuO_{4+y}$ single crystals[1] , ANDREW M. MOUNCE, SANGWON OH, JEONGSEOP A. LEE, W.P. HALPERIN, Northwestern University, A.P. REYES, P.L. KUHNS, National High Magnetic Field Lab, M. CHAN, J. LI, University of Minnesota, D. XIA, X. ZHAO, University of Minnesota, Jilin University, M. GREVEN, University of Minnesota — The high superconducting transition temperature and the simple tetragonal structure of $HgBa_2CuO_{4+y}$ (Hg1201) makes this material an ideal candidate to study unconventional superconductivity in the cuprates[1]. Nuclear magnetic resonance has been performed on Hg1201 single crystals which have been annealed in an ^{17}O atmosphere to achieve superconducting transition temperatures of underdoped 72 K and overdoped 76 K. Oxygen spectra are sufficiently narrow to resolve planar, apical, and dopant oxygen sites in addition to all satellite transitions of the planar and apical sites. The deconvolution of oxygen spin shifts into isotropic and axial shifts, for the underdoped crystal, shows temperature dependence in both the isotropic and axial components of the planar oxygen while the apical oxygen only has temperature dependence in the axial component. The rotational dependence of the apical oxygen shift does not indicate a predicted static local field component due to circulating orbital currents[2] which have been observed by neutron scattering.[3] [1] Barisic, N, PRB 78, 054518 (2008). 12:51PM B35.00009 NMR study of spin fluctuations and superconductivity in $LaFeAsO_{1-x}H_x$[1] , NAOKI FUJIWARA, RYOSUKE SAKURAI, Graduate School of Human & Environmental Studies, Kyoto University, SOUSHI IIMURA, SATORU MATSUISHI, HIDEO HOSONO, Material and structures laboratory (MSL), Tokyo Institute of Technology, YOICHI YAMAKAWA, HIROSHI KONTANI, Department of Physics, Nagoya University and JST, TRIP — We have performed NMR measurements in $LaFeAsO_{1-x}H_x$, an isomorphic compound of $LaFeAsO_{1-x}F_x$. $LaFeAsO_{1-x}H_x$ is most recently known for having double superconducting (SC) domes on H doping. $LaFeAsO_{1-x}H_x$ is an electron- doped system, and protons act as H^{-1} as well as F^{-1}. The first SC dome is very similar between F and H doping, suggesting that H doping supplies the same amount of electrons as F doping. Interestingly, an excess amount of H up to x=0.5 can be replaced with O^{2-}. In the H-overdoped regime ($x > 0.2$), $LaFeAsO_{1-x}H_x$ undergoes the second superconducting state [1]. We measured the relaxation rate of $LaFeAsO_{1-x}H_x$ for x=0.2 and 0.4, and fond an anomalous electronic state; spin fluctuations measured from $1/T_1T$ is enhanced with increasing the doping level from $x = 0.2$ to 0.4. The enhancement of spin fluctuations with increasing carrier doping is a new phenomenon that has not observed in $LaFeAsO_{1-x}F_x$ in which the upper limit of the doping level is at most $x = 0.2$. We will discuss the phenomenon in relation to superconductivity.

1:03PM B35.00010 Electronic and Magnetic Properties of $Ba_{1-x}K_xMn_2As_2$ Studied by ^{55}Mn and ^{75}As-NMR , S. YENINAS, A. PANDEY, D.C. JOHNSTON, Y. FURUKAWA, The Ames Laboratory — $BaMn_2As_2$ (Mn^{2+}; S = 5/2) is a G-type antiferromagnetic (AF) semiconductor with Néel temperature $T_N \sim 625$ K and a small band gap of ~ 27 meV. Hole doping by substitution of Ba with K drives $BaMn_2As_2$ into a metallic state while maintaining the same AF spin structure with similar high T_N. In order to investigate hole doping effects on electronic and magnetic properties in $Ba_{1-x}K_xMn_2As_2$from a microscopic point of view, we have conducted ^{55}Mn and ^{75}As-NMR spectra and spin-lattice relaxation measurements on single crystals of $Ba_{1-x}K_xMn_2As_2$ (x = 0, 0.04, 0.4). The temperature (T) dependence of $1/T_1$ for ^{55}Mn and ^{75}As for the x=0 compound shows $1/T_1 \sim T^3$ dependence for both nuclei, suggesting that $1/T_1$ of the nuclei arises from interactions with magnon excitations in the local-moment AF state. On the other hand, the $1/T_1$ of both nuclei is found to be proportional to T (Korringa relation) in K-doped materials below T_N, which corresponds to the AF metallic state in $Ba_{1-x}K_xMn_2As_2$.

1:27PM B35.00012 High Energy Magnetic Excitations in overdoped high Temperature Superconductors , M. LE TACON, MPI FKF, G. GHIRINGHELLI, Politecnico di Milano, D.C. PEETS, MPI FKF, M. MORETTI-SALA, ESRF, S. BLANCO-CANOSA, MPI FKF, M. MINOLA, Politecnico di Milano, V. HINKOV, MPI-UBC center for Quantum Materials, R. LIANG, D. BONN, W. HARDY, UBC, C.T. LIN, MPI FKF, T. SCHMITT, SLS - PSI, L. BRAICOVICH, Politecnico di Milano, B. KEIMER, MPI FKF — Motivated by the search for the mechanism of high-temperature superconductivity, an intense research effort has been focused on the evolution of the spin excitation spectrum upon doping from the AF insulating to the superconducting (SC) states of the cuprates. Taking advantage of the recent developments of RIXS, we have shown that high energy magnetic excitations with dispersions and spectral weights similar to those of magnons in AF cuprates exist up to optimal doping. In the overdoped region, the normal state appears in many aspects similar to a Fermi liquid, and the available data on the magnetic excitations is rather limited. Inelastic neutron scattering work by Lipscombe et al. revealed the persistence of magnetic excitations up to 160 meV in an overdoped LSCO. This surprising result motivates us to investigate further the high energy magnetic excitations using RIXS in Ca-doped YBCO and Tl2201 compounds. We show that the high energy part of the excitation spectrum is essentially unaffected with hole doping, and that excitations up to 300 meV survive even at doping levels at which SC vanishes.

1:39PM B35.00013 Two Dimensional Incommensurate Spin Excitations and Lattice Fluctuations in $La_{2-x}Ba_xCuO_4$[1] , J.J. WAGMAN, McMaster University, J.P. CARLO, Villanova University, G. VAN GASTEL, McMaster University, Y. ZHAO, National Institute of Standards and Technology, A.B. KALLIN, E. MAZUREK, H.A. DABKOWSKA, Brockhouse Institute for Materials Research, A. SAVICII, G.E. GRANROTH, Oak Ridge National Laboratory, Z. YAMANI, Z. TUN, National Research Council, Canadian Neutron Beam Centre, Chalk River Laboratories, B.D. GAULIN, McMaster University — 'Hour-glass' shaped dispersions of antiferromagnetic (AF) spin fluctuations are a robust feature common to many high temperature superconductors. In 214 cuprates, these phenomena are well known to display a strong dependence on the concentration of holes that are introduced into the copper oxide planes by doping. The incommensurability (IC) of the two dimensional magnetic order in this system is sensitive to hole concentration. Here, we present a series of neutron scattering measurements on single crystals of $La_{2-x}Ba_xCuO_4$ (LBCO), with $0.035 \leq x \leq 0.095$, a doping range that spans the transition from diagonal to parallel IC ordering wavevectors, and from non-superconducting to superconducting ground states. Our measurements map out the evolution of the spin excitations for energies below $\sim$ 50 meV, and focus on an enhancement in the scattered intensity centered in the 17-20 meV at the AF IC positions. This regime corresponds to the approximate crossing of very dispersive spin excitations and weakly dispersive low lying optic phonons in LBCO.

2:03PM B35.00015 Spin Susceptibility Enhancement in Superconductors[1] , BEN ROSEMEYER, ANTON VORONTSOV, Montana State University — We calculate electronic vector-dependent spin susceptibility tensor, $\chi_{\alpha\beta}(\mathbf{q})$, in the superconducting state, for a 2D Fermi surface. We investigate dependence of $\chi_{\alpha\beta}(\mathbf{q})$ on: a) magnetic ordering wave vector $\mathbf{q}$; b) symmetry of the order parameter, $\Delta(\mathbf{k})$; c) temperature; and d) effects of external Zeeman field. We find that under certain conditions longitudinal and transverse components of the susceptibility in the superconducting state can be enhanced compared to the normal state value, indicating effective attraction between magnetically ordered and superconducting phases. In particular, d-wave superconductors at low temperatures in strong magnetic field show increase of χ for $q = 2k_f - \delta q$ ($\delta q/k_f \approx 0.05$) for near-nodal direction of $\mathbf{q}$. We relate such enhancement or lack thereof to behavior of low-energy excitations in the system. These findings may be relevant to materials where magnetic and superconducting phases are close neighbors, such as heavy fermion $CeCoIn_5$, or Fe-based superconductors.

Session B36 DMP: HTSC: Transport Properties 344 - Carmen Almasan, Kent State University

11:15AM B36.00001 Doping dependence of the upper critical field H_{c2} in the cuprate superconductor YBCO

, L. TAILLEFER, N. DOIRON-LEYRAUD, University of Sherbrooke (Canada), D. LEBOEUF, B. VIGNOLLE, C. PROUST, LNCMI, Toulouse (France), B.J. RAMSHAW, R. LIANG, D.A. BONN, W.N. HARDY, University of British Columbia (Canada) — It is generally thought that the upper critical field H_{c2} of underdoped cuprate superconductors is far greater than the vortex-solid melting field $H_{\rm vs}$ at which the state of zero resistance ends, even at $T = 0$ [1]. Here we compare electrical measurements of $H_{\rm vs}$ and thermal measurements of H_{c2} [2] in the cuprate YBCO and show that $H_{c2} = H_{\rm vs}$ at $T \to 0$, strong evidence that there is no vortex liquid phase at $T = 0$. We then present extensive measurements of the electrical resistivity in high magnetic fields over a wide doping range, from which we obtain H_{c2} as a function of doping in YBCO. We find that H_{c2} collapses to remarkably low values in the underdoped regime, which we attribute to the competing effect of a phase with charge-density-wave order [3, 4], also responsible for a reconstruction of the Fermi surface [5, 6].

11:27AM B36.00002 Thermal conductivity as a direct probe of the upper critical field Hc2 in cuprate superconductors

, G. GRISSONNANCHE, O. CYR-CHOINIERE, S. DUFOUR-BEAUSEJOUR, A. JUNEAU-FECTEAU, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, B. RAMSHAW, R. LIANG, D. BONN, W. HARDY, University of British Columbia, S. KRAMER, LNCMI, D. GRAF, NHMFL — The value of the upper critical field H_{c2} in cuprate superconductors is an open question, subject to much debate [1]. Owing to its sensitivity to vortex scattering, the thermal conductivity is a powerful technique to directly measure the upper critical field H_{c2} in a clean type-II superconductor [2]. Here we report measurements of the thermal conductivity in the underdoped cuprate superconductor YBCO in magnetic fields up to 45 T, from which we can directly extract H_{c2}. We find that H_{c2} is remarkably low at a doping $p = 0.11$, showing that quantum oscillations [3, 4] are observed above H_{c2}, in a normal state without vortices.

11:39AM B36.00003 Doping evolution of nodal quasiparticle velocities in cuprate superconductors

, S. RENÉ DE COTRET, J.-PH. REID, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, B.J. RAMSHAW, R. LIANG, D.A. BONN, W.N. HARDY, University of British Columbia — The thermal conductivity of the cuprate superconductor $YBa_2Cu_3O_y$ was measured at temperatures down to $T \sim 50$ mK on high-quality single crystals with a hole doping ranging from $p = 0.06$ to $p = 0.18$. The residual linear term at $T \to 0$ is a direct measure of the ratio of nodal quasiparticle velocities. When combined with published data on $Tl_2Ba_2CuO_{6+\delta}$ [1], our data spans the full superconducting phase. The ratio of quasiparticle velocities agrees well with recent, high-resolution ARPES measurements of the Fermi velocity and gap velocity at the nodes as a function of doping, in the related cuprate superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ [2,3].

11:51AM B36.00004 Hall and Nernst Coefficients of Underdoped $HgBa_2CuO_{4+\delta}$: Fermi-Surface Reconstruction in an Archetypal Cuprate Superconductor

, NICOLAS DOIRON-LEYRAUD, Universite de Sherbrooke, S. LEPAULT, LNCMI Toulouse, O. CYR-CHOINIÈRE, Universite de Sherbrooke, B. VIGNOLLE, LNCMI Toulouse, F. LALIBERTÉ, J. CHANG, Universite de Sherbrooke, N. BARIŠIĆ, M.K. CHAN, L. JI, X. ZHAO, University of Minnesota, Y. LI, Peking University, M. GREVEN, University of Minnesota, C. PROUST, LNCMI Toulouse, LOUIS TAILLEFER, Universite de Sherbrooke — The Hall coefficient $R_{\rm H}$ of underdoped $HgBa_2CuO_{4+\delta}$ (Hg1201) was measured at low temperature in magnetic fields large enough to suppress superconductivity. The normal-state $R_{\rm H}(T)$ is found to drop with decreasing temperature and become negative below 10 K, as also observed in the orthorhombic bi-layer cuprate $YBa_2Cu_3O_y$ (YBCO) at comparable doping. In YBCO, the negative $R_{\rm H}$ is the signature of a Fermi-surface reconstruction that produces a small electron pocket, attributed to the onset of charge-density wave order at low temperature. We infer that a similar Fermi-surface reconstruction occurs in the tetragonal single-layer material Hg1201. A striking similarity is also found in the normal-state Nernst coefficient $\nu(T)$, which drops below the pseudogap temperature $T^\star$, to reach a large negative value at low temperature, in both Hg1201 and YBCO. Our results are compelling evidence that the mechanisms responsible for Fermi-surface reconstruction and pseudogap formation in hole-doped cuprates are universal. Preprint reference: arXiv:1210.8411.

12:03PM B36.00005 Doping dependence of the upper critical field in the electron-doped cuprate superconductor PCCO via the Nernst effect

, F. LALIBERTÉ, F.F. TAFTI, M. DION, J. GAUDET, P. FOURNIER, L. TAILLEFER, Université de Sherbrooke — Superconducting fluctuations are known to persist above the critical temperature $T_{\rm c}$ and above the upper critical magnetic field H_{c2}. The Nernst effect was shown to be a powerful probe of these fluctuations [1], in quantitative agreement with theory [2]. Here we report a detailed study of the Nernst effect in high-quality films [3] of the electron-doped cuprate superconductor PCCO, from which we extract H_{c2} as a function of doping. We find that H_{c2} follows the dome-like doping dependence of $T_{\rm c}$, revealing that the pairing strength decreases with underdoping, as it does in hole-doped cuprates [4].

12:15PM B36.00006 Resistivity in the pseudogap phase of the underdoped cuprates

, PHILLIP ASHBY, JULES CARBOTTE, McMaster University — The pseudogap phase of the underdoped cuprates remains poorly understood. It exhibits many anomalous electronic properties. One example is the dc-resistivity which is metallic in the copper oxygen planes, while the c-axis response is insulating. We show how this can be understood within the pseudogap model of Yang, Rice, and Zhang (YRZ). The YRZ model naturally reconstructs the Fermi surface as a function of doping. This reconstruction places limits on the remaining quasiparticles allowed to participate in transport. As a result, the model is able to reproduce the qualitative experimental signatures, including the deviations from linear resistivity in the plane, as well as the insulating response along the c-axis.

12:27PM B36.00007 Impurity Effects on Superconducting Properties coming from Nontrivial Nodal Structures in Order Parameters[1] , HEESANG KIM, HYUNHEE CHUNG, NAMMEE KIM, Department of Physics, Soongsil University, Seoul 156-743 Korea — Power-law behavior is expected in the temperature dependence of the specific heat in a superconductor whose order parameter has point- or line-nodes on its fermi surface. It is known that the dependence is T^2 for line-nodes and T^3 for point-nodes. However, the power-law behavior is different from what we expect in some cases such as g-wave and $g + s$-wave. We present the generalized power-law behavior in a superconductor with a nontrivial nodal structure in its order parameter. We also show how the presence of impurities wash out the power-law behavior. In the framework of the quasiclassical formalism, we focus on the density of states and the specific heat. We also present evolution of those quantities in the presence of impurities. The impurity effect is parameterized with two quantities, the scattering cross section σ and impurity scattering rate $1/2\tau$, so that we can cover the whole range of the impurity effect from the Born limit to the unitary limit.

12:39PM B36.00008 Conventional c-axis charge transport in the electron-doped cuprates[1] , YANGMU LI, N. BARIŠIĆ, G. YU, School of Physics and Astronomy, University of Minnesota, Minneapolis, MN 55455, E.M. MOTOYAMA, I.M. VISHIK, Departments of Physics and Applied Physics, Stanford University, Stanford, CA 94305, S.T. HANNAHS, National High Magnetic Field Laboratory, Tallahassee, FL, 32310, M. GREVEN, School of Physics and Astronomy, University of Minnesota, Minneapolis, MN 55455 — We have measured the interlayer (c-axis) magnetoresistivity of the electron-doped cuprate superconductor $Nd_{2-x}Ce_xCuO_{4+\delta}$(NCCO) at and below optimal doping. In zero magnetic field, the low- and intermediate-temperature regimes are dominated by logarithmic and quadratic temperature dependences, respectively. The low-temperature logarithmic upturn indicates the onset of localization, whereas the quadratic dependence is attributed to Fermi-liquid behavior. Furthermore, the transverse c-axis magnetoresistivity exhibits H^2 dependence, not only above the zero-field Tc, but also at lower temperature once a sufficiently large external field suppresses the superconductivity. These findings suggest that the out-of-plane conduction in the electron-doped cuprates is rather conventional.

12:51PM B36.00009 ABSTRACT WITHDRAWN –

1:03PM B36.00010 Universal sheet resistance of the cuprate superconductors , N. BARIŠIĆ, University of Minnesota, USA, and CEA-DSM-IRAMIS, France, M.K. CHAN, G. YU, University of Minnesota, Y. LI, Peking University, China, X. ZHAO, Jilin University, China, M. DRESSEL, Universität Stuttgart, Germany, A. SMONTARA, Institute of Physics, Croatia, M. GREVEN, University of Minnesota — Upon introducing charge carriers into the underlying copper-oxygen sheets of the cuprates, the parent insulator evolves into a superconductor and eventually into a seemingly conventional Fermi liquid. Much has remained elusive about the nature of this evolution, and about the peculiar metallic state at intermediate hole-carrier concentrations (p), where the planar resistivity exhibits a linear temperature dependence ($\rho \propto T$) that is disrupted upon cooling toward the superconducting state by the opening of a 'pseudogap' along the Fermi surface. Here we demonstrate for the quintessential compound $HgBa_2CuO_{4+\delta}$ a purely Fermi-liquid-like resistivity ($\rho \propto T^2$) deep in the pseudogap regime. Our result when combined with select prior work for other compounds reveals the fundamental resistance per copper-oxygen sheet in both the linear ($\rho_S = A_{1S}T$) and quadratic ($\rho_S = A_{2S}T^2$) regimes, with $A_{1S} \propto \quad A_{2S} \propto 1/p$. Theoretical models for the cuprates can now be benchmarked against this remarkably simple universal behavior. *Preprint: arXiv:1207.1504.* Work supported by DOE-BES.

1:15PM B36.00011 Magnetotransport of $La_{(2-x)}Sr_xCuO_4$ with nearly continuous doping in intense magnetic fields , ZACHARY STEGEN, GREG BOEBINGER, Florida State University, JIE WU, IVAN BOZOVIC, Brookhaven National Lab, FEDOR BALAKIREV, ALBERT MIGLIORI, Los Alamos National Lab — Pulsed magnetic fields of up to 57 T were used to measure the Hall resistivity and longitudinal magnetoresistance of $La_{(2-x)}Sr_xCuO_4$ to low temperatures by suppressing the superconducting state. The samples were grown using Combinatorial Molecular Beam Epitaxy (COMBE) where the Sr concentration – and hence carrier doping, p – changes continuously across the sample. Performing 30 simultaneous transport measurements on a single growth allows for unprecedented resolution in doping ($\Delta p \approx 0.0002$). We examine the phase diagram of the resistive state in this hole-doped cuprate by measuring a series of COMBE samples.

1:27PM B36.00012 Transport and contact-free investigation of REBCO thin film temperature dependent pinning landscapes , JOHN SINCLAIR, JAN JAROSZYNSKI, XINBO HU, MICHAEL SANTOS, National High Magnetic Field Laboratory — Studies of the pinning mechanisms and landscapes of $REBa_2Cu_3O_x$ (RE=rare earth elements) thin films have been a topic of study in recent years due to, among other reasons, their ability to introduce nonsuperconducting phases and defects. Here we will focus on REBCO thin films with $BaZrO_3$ nanocolumns and other isotropic defects. The evolution of the dominant pinning mechanisms seems to change as a function of temperature even to the point that samples with similar critical current density properties at high temperatures can have distinctly different properties at low temperatures. Earlier work focused on the angular selectivity of the current density profile, though other properties (such as alpha values) can evolve as well. Characteristic results accentuating this evolution of current density properties will be presented. Challenges exist in evaluating these low temperature properties in high magnetic fields, therefore both transport and contact-free results were be presented to compliment the work. Support for this work is provided by the NHMFL via NSF DRM 0654118.

1:39PM B36.00013 Contact free transport characterization of recent REBCO films in very high magnetic field[1] , JAN JAROSZYNSKI, JOHN SINCLAIR, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, VALERIA BRACCINI, CNR-SPIN, Corso Perrone 24, I-16152 Genova, Italy, XINBO HU, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310 — Studies on pinning mechanisms in high temperature superconductors often require detailed knowledge of critical current density J_c as a function of magnetic field orientation as well as field strength and temperature. However, recent $REBa_2Cu_3O_x$ (RE=rare earth elements) thin films can achieve remarkably high critical current density values by the incorporation of nonsuperconducting nanoparticles, that often pose problems with J_c measurements, due to extremely high Lorentz force, Joule heating etc. in the limited space of high field magnets. Here we demonstrate the angularly dependent J_c measured by means of contact-free vector magnetization measurements in a vibrating sample magnetometer equipped with both longitudinal and transverse pickup coils. The studies complement traditional transport techniques and are readily extended to conditions of fields and temperatures where the current density is very large and transport methods become difficult. Our results clearly show an evolution of pinning from strongly correlated effects seen at high temperatures to significant contributions from dense but weak pins that thermal fluctuations render ineffective at high temperatures but which become strong at lower temperatures

1:51PM B36.00014 Linear and quadratic temperature dependence of electronic specific heat for cuprates[1] , P. SALAS[2], F.J. SEVILLA, M.A. SOLIS, Instituto de Fisica, UNAM — We model cuprate superconductors as an infinite layered lattice structure which contains a fluid of paired and unpaired fermions (electrons or holes). Paired fermions, which are the superconducting carriers, are considered as noninteracting zero spin bosons (cuasi-particles) with a linear dispersion relation, which coexist with the unpaired fermions in a series of almost two dimensional slabs stacked in their perpendicular direction. The inter-slab penetrable planes are simulated by a Dirac comb potential in the direction in which the slabs are stacked, while paired and unpaired electrons (or holes) are free to move parallel to the planes. Paired fermions condense at a BEC critical temperature exhibiting a jump in their specific heat, which are taken as the experimental values of the superconducting critical temperature and the specific heat jump of $YBaCuO_{7-x}$, to fix our model parameters: the plane impenetrability and the fraction of superconducting charge carrier. We straightforwardly obtain, near and under the superconducting temperature T_c, the linear ($\gamma_e T$) and the quadratic (αT^2) electronic specific heat terms, with γ_e and α in agreement with the latest experimental values reported.

Session B37 DMP DCOMP: Focus Session: Fe-based Superconductors: Impurity Effects 345/346

- Ruslan Prozorov, Ames Lab

11:15AM B37.00001 Effect of heavy-ion and electron irradiation on properties of Fe-based superconductors , MARCIN KONCZYKOWSKI, Laboratoire des Solides Irradies, Ecole Polytechnique, CNRS-UMR7642, CEA-DSM-IRAMIS, 91128 Palaiseau, France — The introduction of defects by particle irradiation is used to reveal the role of disorder in matter, which is unavoidable in all crystalline solids. In superconductors defects introduce flux pinning, controlling critical current, J_c; as well as pair-breaking scattering, limiting the critical temperature, T_c. To elucidate defect related properties of Fe-based superconductors (FBS) we precede in two types of irradiation: heavy ion (6GeV Pb) to create disorder in the form of amorphous tracks and low temperature electron irradiation (2.5MeV at 20K) to create point like defects. Substantial increase of irreversible magnetization and an upward shift of the irreversibility line are observed after heavy ion irradiation of all FBS investigated to date. In $BaK122$, signatures of a Bose-glass vortex state; angular dependence and variable-range hopping flux creep are revealed. Remarkably, heavy ion irradiation does not depress T_c, however, point-like disorder introduced by electron irradiation does substantially. In isovalently substituted $Ba(FeAs_{1-x}P_x)_2$ and $Ba(Fe_{1-x}Ru_xAs)_2$ crystals, T_c decreases linearly with dose. Suppression to 40% of initial value of T_c was achieved in $Ba(FeAs_{1-x}P_x)_2$. An increase of normal state resistivity is observed and correlated to depression of T_c. Change of superconducting gap structure with disorder was determined from penetration depth measurements, $\lambda(T)$ dependence, at various stages of irradiation. Linear in T variation of pristine samples, indicative of the presence of nodes in gap, turned at low irradiation dose to exponential T variation, indicative of a fully gaped state. T^2 variation of λ is observed at higher doses. This behaviour is incompatible with symmetry-imposed nodes of d-wave pairing but consistent with $S+/-$, $S+/+$ mechanisms. This is the first observation of the impurity-induced node lifting expected in anisotropic s-wave superconductors

11:51AM B37.00002 Impurity-induced changes in the superconducting order parameter in iron-based superconductors $BaFe_2(As_{1-x}P_x)_2$, YUTA MIZUKAMI, Y. KAWAMOTO, K. HASHIMOTO, S. KASAHARA, Department of Physics, Kyoto University, M. KONCZYKOWSKI, C.J. VAN DER BEEK, B. BOIZOT, Ecole Polytechnique, R. PROZOROV, The Ames Laboratory, Y. WANG, A. KREISEL, P.J. HIRSCHFELD, Department of Physics, University of Florida, V. MISHRA, Materials Science Division, Argonne National Laboratory, Y. MATSUDA, T. SHIBAUCHI, Department of Physics, Kyoto University — To determine the symmetry and structure of superconducting order parameter in iron-based superconductors is one of the prime challenges in strongly correlated electron systems. A systematic study on the effect of impurity scattering on the structure of superconducting order parameter can be used to distinguish S++ and S+- symmetry. We introduced the point defects on iron-based superconductors $BaFe_2(As_{1-x}P_x)_2$ by electron irradiation which does not change lattice constants and carrier density, and performed magnetic penetration depth measurements on those samples. Here, we report on the suppression of the critical temperature and the change of the superconducting gap structure in iron-based superconductors $BaFe_2(As_{1-x}P_x)_2$ with increasing the defect density, from which we discuss the superconducting symmetry in this system.

12:03PM B37.00003 Theoretical study of impurity effects in iron-based superconductors , MARIA NAVARRO GASTIASORO, University of Copenhagen, PETER HIRSCHFELD, University of Florida, BRIAN ANDERSEN, University of Copenhagen — Several open questions remain unanswered for the iron-based superconductors (FeSC), including the importance of electronic correlations and the symmetry of the superconducting order parameter. Motivated by recent STM experiments which show a fascinating variety of resonant defect states in FeSC, we adopt a realistic five-band model including electronic Coulomb correlations to study local effects of disorder in the FeSC. In order to minimize the number of free parameters, we use the pairing interactions obtained from spin-fluctuation exchange to determine the homogeneous superconducting state. The ability of local impurity potentials to induce resonant states depends on their scattering strength V_{imp}; in addition, for appropriate V_{imp}, such states are associated with local orbital- and magnetic order. We investigate the density of states near such impurities and show how tunneling experiments may be used to probe local induced order. In the SDW phase, we show how C2 symmetry-breaking dimers are naturally formed around impurities which also form cigar-like (pi,pi) structures embedded in the (pi,0) magnetic bulk phase. Such electronic dimers have been shown to be candidates for explaining the so-called nematogens observed previously by QPI in Co-doped $CaFe_2As_2$.

12:15PM B37.00004 Enhancement of T_c by impurity scattering in underdoped iron-arsenide superconductors[1] , MAXIM G. VAVILOV, University of Wisconsin-Madison, Madison, WI 53706, RAFAEL M. FERNANDES, University of Minnesota, Minneapolis, MN 55455, ANDREY V. CHUBUKOV, University of Wisconsin-Madison, Madison, WI 53706 — When analyzing the effects of disorder on the superconducting transition temperature T_c of the iron pnictides, the conventional wisdom is that inter-band impurity scattering is quite harmful to the $s^{\pm}$ state. In this talk, we show that this is the case only in the overdoped region of the phase diagram. In the underdoped region, impurity scattering gives rise to two opposite effects due to the competition between superconductivity and a pre-existing magnetic state. The first effect is the direct reduction of T_c due to the pair-breaking contribution coming from inter-band impurity scattering. The second effect is an indirect increase in T_c due to the suppression of long-range magnetic order by both intra-band and inter-band impurity scattering. We show that for a wide range of parameters the second effect overcomes the first, leading to an overall enhancement of T_c by disorder. Our results explain recent puzzling experimental observations on the impact of disorder on T_c of the iron pnictides, providing further evidence in favor of an $s^{\pm}$ pairing state.

[1]Research funded by: NSF-PIRE Program No. OISE-0968226, ICAM and NSF-DMR 0645461, NSF-DMR 0955500, and NSF-DMR 0906953

12:27PM B37.00005 Using controlled disorder to distinguish $s_{\pm}$ and s_{++} gap structure in Fe-based superconductors[1] , YAN WANG, ANDREAS KREISEL, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, VIVEK MISHRA, Materials Science Division, Argonne National Laboratory, Lemont, IL 60439, USA — We reconsider the effect of disorder on the properties of a superconductor characterized by a sign-changing order parameter appropriate for Fe-based materials. Within a simple two band model, we calculate simultaneously T_c, the change in residual resistivity $\Delta\rho_0$, and the zero-energy density of states, and show how these results change for various types of gap structures and assumptions regarding the impurity scattering. The rate of T_c suppression is shown to vary dramatically according to details of the impurity model considered. We search therefore for a practical, experimentally oriented signature of a gap of the $s_{\pm}$ type, and propose that observation of particular evolution of the penetration depth, thermal conductivity or NMR temperature dependence with disorder would suffice.

12:39PM B37.00006 Single nonmagnetic impurity resonance in FeSe-based 122-type superconductors as a probe for pairing symmetry , QIAN-EN WANG, ZI-JIAN YAO, FU-CHUN ZHANG, Department of Physics and Center of Theoretical and Computational Physics, the University of Hong Kong — The effect of a single nonmagnetic impurity in $A_yFe_{2-x}Se_2$ (A=K, Rb, or Cs) superconductors has been studied based on a three-orbital model. The local density of states on and near the impurity site has been calculated by solving the Bogoliubov-de Gennes equations self-consistently. Both repulsive and attractive impurity scattering potential are considered in our calculations. The impurity-induced in-gap bound states are found only for attractive scattering potential in the state of $d_{x^2-y^2}$ wave pairing, and it turns out that they are very sensitive to the magnitude of the scattering potential. The emergence of the impurity-induced bound states in the vicinity of the Fermi level demonstrates a strong violation of the electron-hole symmetry which is originated from the nodeless $d_{x^2-y^2}$ wave pairing state. The results obtained in our calculation, which simulate the doping of Co and Ni in FeSe-based 122-type superconductors, as an approach to examine the pairing symmetry of this novel superconducting material, can be a proposal of STM observation.

12:51PM B37.00007 Effect of electron irradiation on superconductivity in isovalently substituted $Ba(Fe_{1-x}Ru_x)_2As_2$, RUSLAN PROZOROV, M.A. TANATAR, A. THALER, S.L. BUD'KO, P.C. CANFIELD, The Ames Laboratory, Ames, IA 50011, USA, M. KONCZYKOWSKI, LSI, Ecole Polytechnique, Palaiseau, France, T. SHIBAUCHI, Dept. of Physics, Kyoto Univ., Kyoto, Japan — Single crystals of isovalently substituted $Ba(Fe_{1-x}Ru_x)_2As_2$ were irradiated at 23 K by 2.5 MeV electrons with a total fluence up to 2×10^{19} electrons per cm^2. The resistance was measured both in situ at 23 K during irradiation, and as a function of temperature in a separate set-up, between the irradiation runs while the sample warmed to room temperature. We found that $\Delta\rho_0/\rho_0\approx0.2$ change in the residual resistivity, reached at the maximum irradiation dose, led to about a $\Delta T_c/T_{c0}\approx0.35$ decrease of T_c. This trend is universal in samples of different doping levels with different initial T_{c0}. The in-situ measurements also allowed us to understand the effects of room temperature annealing on the point-like defects induced by irradiation. The annealing results in a decrease of about a 20% of the total increase in resistance achieved due to irradiation. However, residual 80% remain stable at least one month after irradiation. We compare our results with theoretical predictions for different pairing scenarios, including extended $s_{\pm}$. Work in Ames was supported by the Department of Energy Office of Science, Basic Energy Sciences under Contract No. DE-AC02-O7CH11358.

1:03PM B37.00008 Theoretical visualization of atomic-scale impurity states in Fe-based superconductors[1] , PEAYUSH CHOUBEY, PETER HIRSCHFELD, TOM BERLIJN, University of Florida, CHAO CAO, Hangzhou Normal University — We study the impurity induced local density of states (LDOS) in Fe-based superconductors, incorporating Wannier functions to obtain a higher resolution derived from a downfolding of density functional theory bands onto a 10-Fe tight-binding model. This enables us to compare our results with those obtained experimentally using STM. We solve the ten orbital Bogoliubov-de Gennes (BdG) equations for the single impurity problem and obtain the superconducting state lattice space Green's function, which is then transformed to the Wannier basis. The utility and limitations of this approximation are discussed.

1:15PM B37.00009 Effects of disordered Ru substitution in $BaFe_2As_2$: possible superdiffusion mechanism in real materials[1] , LIMIN WANG, TOM BERLIJN, Brookhaven National Lab, YAN WANG, University of Florida, CHIA-HUI LIN, Brookhaven National Lab, State university of New York, Stony Brook, PETER HIRSCHFELD, University of Florida, WEI KU, Brookhaven National Lab, State university of New York, Stony Brook — An unexpected insensitivity of the Fermi surface to impurity scattering is found in Ru substituted $BaFe_2As_2$ from first-principles theory, offering a natural explanation of the unusual resilience of transport and superconductivity to a high level of disordered substitution in this material. This robustness is shown to originate from a coherent interference of correlated on-site and inter-site impurity scattering, similar in spirit to the microscopic mechanism of superdiffusion in one dimension. Our result also demonstrates a strong substitution dependence of the Fermi surface and carrier concentration, and provides a natural resolution to current discrepancies in recent photoelectron spectroscopy. These effects offer a natural explanation of the diminishing long-range magnetic, orbital and superconducting order with high substitution.

1:27PM B37.00010 Electron irradiation of iron-based superconductors , S. DEMIRDIS, C.J. VAN DER BEEK, M. KONCZYKOWSKI, Laboratoire des Solides Irradiés, CNRS UMR 7642 & CEA-DSM-IRAMIS, Ecole Polytechnique, F-91128 Palaiseau cedex, France, S. KASAHARA, T. TERASHIMA, Research Center for Low Temperature and Materials Sciences, Kyoto University, Sakyo-ku, Kyoto 606-8501, Japan, R. OKAZAKI, T. SHIBAUCHI, Y. MATSUDA, Department of Physics, Kyoto University, Sakyo-ku, Kyoto 606-8501, Japan, D. COLSON, Service de Physique de l'Etat Condensé, L'Orme des Mérisiers, CEA-DSM-IRAMIS, F-91198 Gif-sur-Yvette, France, P. GIERLOWSKI, Institute of Physics of the Polish Academy of Sciences, 32-46 Aleja Lotników, R. PROZOROV, The Ames Laboratory, Ames, Iowa 50011, USA Department of Physics & Astronomy, Iowa State University, Ames, Iowa 50011, USA — The premise of $s_{\pm}$ superconductivity in the multiband iron-based superconductors, with a sign-changing order parameter between the electron-like and hole-like Fermi-surface sheets, has raised the question of the effect of atomic-scale point-like disorder on superconductivity in these materials. In this contribution, we compare the effect of the controlled introduction of point-like defects in different 122-type iron-based superconductors by 2.5 MeV electron irradiation at 20 K. Preliminary data reveal that the effect point-like defects on the critical temperature of isovalently doped materials vastly outweighs that on the charge-doped compounds. The weak collective contribution to J_c in Co-doped 122 compounds is found to clearly increase. Moreover this contribution appears after irradiation of the P-doped compound in which it was previously absent.

1:39PM B37.00011 Impurity substitution effect on Dirac cone in $Ba(FeAs)_2$ studied by magnetoresistance , TAKAHIRO URATA, YOICHI TANABE, KHUONG HUYNH, SATOSHI HEGURI, Department of physics, Graduate school of science, Tohoku University, Aoba, Aramaki, Aoba-ku, Sendai, 980-8578, Japan, HIDETOSHI OGURO, KAZUO WATANABE, High Field Laboratory for Superconducting Materials, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, KATSUMI TANIGAKI, WPI-Advanced Institutes of Materials Research, Tohoku University, Aoba, Aramaki, Aoba-ku, Sendai 980-8578, Japan — In iron pnictide superconductors, the three dimensional Dirac cones (DCs) are created as a node of spin-density-wave gap [1]. Due to the pseudospin chirality, these DCs are robust for both nonmagnetic and magnetic impurities. Here we report Ru and Mn substitution effects on DCs in $Ba(FeAs)_2$ studied by magnetoresistance [2]. We assume that Ru is the nonmagnetic impurity while Mn is the magnetic one due to the stability of the $Mn^{2+}(3d^5)$ state. A linear magnetoresistance (LMR) against magnetic field (B) was observed above the certain magnetic field strength of B* for both cases. LMR in $Ba(Fe_{1-x}Ru_xAs)_2$ is consistent with the quantum limit of DC [3,4]. Temperature (T) dependence of B* deviated from the theoretical model at low T for $Ba(Fe_{1-x}Mn_xAs)_2$. This can be understood in term of the decrease of Fermi velocity of DCs, being associated with the magnetic scattering effect on DCs. [1] Y. Ran et al., Phys. Rev. B 79, 014505 (2009).[2]Y. Tanabe et al., Phys. Rev. B 84, 100508(R) (2011). /Phys. Rev. B 86, 094510 (2012). [3]A. A. Abrikosov, Phys. Rev. B 58, 2788 (1998).[4]K. K. Huynh et al., Phys. Rev. Lett. 106, 217004 (2011).

1:51PM B37.00012 Effect of electron irradiation on superconductivity in isovalently substituted $Ba(Fe_{1-x}Ru_x)_2As_2$ and $SrFe_2(As_{1-x}P_x)_2$, C.P. STREHLOW, A. THALER, M.A. TANATAR, S.L. BUD'KO, P.C. CANFIELD, R. PROZOROV, The Ames Laboratory, M. KOCZYKOWSKI, LSI, Ecole Polytechnique, S. MIYASAKA, Osaka University — Single crystals of isovalently substituted $Ba(Fe_{1-x}Ru_x)_2$ As_2 and $SrFe_2(As_{1-x}P_x)_2$ were irradiated at 23 K by 2.5 MeV electrons with a total fluence up to 2×10^{19} electrons per cm^2. Both the resistivity and Hall coefficient were measured before and after irradiation using the van der Pauw method. Irreversible vortex properties were probed using miniature Hall-probe arrays. We correlate the change in resistivity due to irradiation with changes in flux pinning, relaxation rate and irreversibility line. We compare the results with theoretical predictions for different pairing scenarios, including extended $s_{\pm}$.

2:03PM B37.00013 Understanding the role of disorder in Fe-arsenide superconductors , JAMES ANALYTIS, University of California Berkeley, HSUEH-HUI KUO, Stanford University, IAN FISHER, Stanford Univeristy — Disorder has a profound affect on iron-pnictide superconductors, changing the transport anisotropy, the magneto-elastic coupling, and the properties of the superconductivity itself. In the 122 structural motifs, the parent compounds have a folded band structure with compensated hole and electron pockets. Some of these pockets are thought to be protected from disorder by the topological properties of the band structure. However, the influence of disorder on each pocket is in general very difficult to reveal because transport properties will in general measure an average of all Fermi surfaces, and other Fermi surface probes (such as ARPES) will not be sensitive to subtle changes in the dynamical properties of each Fermi surface. We present results of detailed quantum oscillation studies which aim to understand how the dynamics of each Fermi surface pocket is affected by disorder.

Session B38 FEd: Focus Session: Building a Thriving Undergraduate Physics Program 347 - Ted Hodapp, American Physical Society

11:15AM B38.00001 From Near Extinction to Academic Excellence: The University of Wisconsin-La Crosse Physics Program , GUBBI SUDHAKARAN, University of Wisconsin-La Crosse — A physics department that was on the brink of extinction has been successfully resuscitated into a nationally recognized program at the University of Wisconsin-La Crosse (UW-L). The revitalization efforts included sweeping curricular reforms, aggressive recruitment, and retention of students and faculty. The reforms included the introduction of new academic programs for the majors, new courses for non-majors, a dual-degree program in Physics and Engineering, and opportunities for undergraduate research. The department uses several recruitment techniques which include contacting high school seniors in the region and conducting outreach activities to attract students to the program. In order to sustain and enhance the quality of the program, the department carries out comprehensive assessment of its programmatic goals on a regular basis. The department is also very successful in placing students with bachelor's degrees in physics in STEM careers at an exceptional rate. The success of the program in recruiting, retention, and career placement can be attributed to a combination of aggressive advising and flexible options designed to meet the needs and career goals of each student. The retention rate in the program is high due to one-on-one advising, involving students in undergraduate research at an early stage, and a very vibrant student society. Due to these initiatives, the department has maintained its growth over the years with 160 majors currently, and 29 majors graduating during the 2011- 2012 academic year. Recently, the UW-L Physics Program was selected to receive the 2013 American Physical Society (APS) "Improving Undergraduate Physics Education Award".

11:51AM B38.00002 Increasing student success[1] , GAY STEWART, JOHN STEWART, University of Arkansas — A more scientifically literate society benefits all STEM disciplines, as well as society as a whole. It is best realized by better serving all undergraduate STEM students. In better-serving all students, a physics department also benefits. The University of Arkansas, Fayetteville physics department has seen a drastic change in number of majors, the number of students active in research and the number of graduates pursuing graduate work, while also increasing the number of majors who decide to teach. Prior to our involvement with the Physics Teacher Education Coalition, graduation rates had increased by more than a factor of 4 in 4 years. After the increased efforts when we became a part of PhysTEC (http://PhysTEC.org) our graduation numbers doubled again. Specific attention to class policy to impact student learning in our introductory courses and strong preparation of the graduate teaching assistants, and quality advising were our primary areas of emphasis. What worked to build these numbers and strengthen these resources at Arkansas will be discussed.

[1]This work was supported in part by the National Science Foundation and through the Physics Teacher Education Coalition.

12:03PM B38.00003 SPIN-UP Regional Workshops: Enhancing Undergraduate Physics Programs , ROBERT HILBORN, American Association of Physics Teachers, RUTH HOWES[1], Marquette University, KENNETH KRANE, Oregon State University — Through a grant from the National Science Foundation Division of Undergraduate Education (0741560), the American Association of Physics Teachers has been hosting a series of regional workshops for teams of faculty members from physics departments across the country. The goal of the program is to help departments develop and implement plans to enhance their undergraduate programs for both majors and non-majors. We give a brief overview of the Strategic Plans for Innovations in Undergraduate Physics (SPIN-UP) effort, the characteristics of "thriving undergraduate physics programs" articulated in the SPIN-UP report, and the six regional workshops. We provide data on physics majors' enrollment and graduation data at the participating departments to assess the impact of the program.

[1]retired

12:15PM B38.00004 SPIN-UP Regional Workshops: Texas Physics Programs and Physics Programs at HBCUs , BETH CUNNINGHAM, American Association of Physics Teachers, PAUL GUEYE, Hampton University, MICHAEL MARDER, University of Texas-Austin, JAMES STITH, American Institute of Physics, QUINTON WILLIAMS, Jackson State University — As part of the broader SPIN-UP Regional Workshops program, the American Association of Physics Teachers organized two workshops directed at specific audiences. In May 2011, Hampton University hosted a SPIN-UP workshop focusing on physics programs at Historically Black Colleges and Universities. In May 2012, the University of Texas at Austin hosted a workshop focusing on physics programs in Texas, many of which were affected by a decision of the Texas Higher Education Coordinating Board to eliminate degree programs (in all fields) that produced fewer than five majors per year averaged over the most recent three-year period. We will summarize the discussions at these meetings and what is being done to respond to the challenges faced by the physics departments attending the workshops.

12:27PM B38.00005 Learning by doing at the Colorado School of Mines , THOMAS E. FURTAK, TODD G. RUSKELL, Colorado School of Mines — With over 260 majors, the undergraduate physics program at CSM is among the largest in the country. An underlying theme in this success is experiential learning, starting with a studio teaching method in the introductory calculus-based physics courses. After their second year students complete a 6-week full-time summer course devoted to hands-on practical knowledge and skills, including machine shop techniques, high-vacuum technology, applied optics, electronic control systems, and computational tools. This precedes a two-semester laboratory sequence that can be taught at an advanced level because of the students' experience. The required capstone senior course is a year-long open-ended challenge in which students partner with members of the faculty to work on authentic research projects, teaming with grad students or post-docs as contributing members to the department's externally funded scholarship. All of these features are important components of our B.S. degree, Engineering Physics, which is officially accredited by ABET.

12:39PM B38.00006 Physics Teacher Preparation as a Means for Growth[1] , RON HENDERSON, Middle Tennessee State University — Physics departments across the country are experiencing pressures to increase the number of graduates. One response is to improve marketing and recruiting efforts to add students to existing pipelines. A more innovative approach is to create new pathways tied to career paths that are alternatives to graduate school. One occupation that currently needs more graduates than physics departments are supplying is physics teaching. About 3 years ago, MTSU began implementing a strategy to prepare physics majors for careers in high school teaching. These efforts included developing coursework specifically related to physics teaching, creating relationships with the college of education, moving to pedagogies that reflect physics education research (PER)-validated best practices, hiring a tenure-track PER expert, implementing new ways to reach potential majors, and seeking external funding. The cumulative result has not only added a number of physics teaching majors to our roles, but has affected our existing programs in a manner that has yielded further growth.

[1]Support provided by the APS/AAPT PhysTEC project.

12:51PM B38.00007 Positive Aspects and Challenges Associated with Program Growth in Towson University's Physics Department , DAVID SCHAEFER, Towson University — Towson University's physics department has experienced dramatic growth over the past five years. Many directed and strategic initiatives have been implemented to increase student enrollment and retention. This has resulted in an increase from approximately 60 majors in 2007 to 115 in 2012. Graduation numbers have also seen a corresponding increase. This presentation will discuss efforts taken to produce these results as well as information related to the positive and negative aspects of growth. Future directions and plans to deal with challenges encountered will be discussed.

1:03PM B38.00008 Retention at Departments of Physics , RAFAEL MULLER, LUIS ROSA, University of Puerto Rico - Humacao — A thriving physics department is the end result of many actions, taken over time, that results in the development of a sense of community between the faculty and the students. As part of this sense of community, gifted students must receive special attention and innovative ideas must be incorporated to successfully accommodate the needs of these students. We have found that the best retention strategy for gifted undergraduates is the total involvement of them in undergraduate research projects and also the development of leadership in extracurricular activities within the department. A careful employment strategy is needed to secure a faculty committed to the goals of the community.

1:15PM B38.00009 Biological Physics major as a means to stimulate an undergraduate physics program , HERBERT JAEGER, KHALID EID, JAN YARRISON-RICE, Miami University — In an effort to stress the cross-disciplinary nature of modern physics we added a Biological Physics major. Drawing from coursework in physics, biology, chemistry, mathematics, and related disciplines, it combines a broad curriculum with physical and mathematical rigor in preparation for careers in biophysics, medical physics, and biomedical engineering. Biological Physics offers a new path of studies to a large pool of life science students. We hope to grow our physics majors from 70-80 to more than 100 students and boost our graduation rate from the mid-teens to the mid-twenties. The new major brought about a revision of our sophomore curriculum to make room for modern topics without sidelining fundamentals. As a result, we split our 1-semester long Contemporary Physics course (4 cr hrs) into a year-long sequence Contemporary Physics Foundations and Contemporary Physics Frontiers (both 3 cr hrs). Foundations starts with relativity, then focuses on 4 quantum mechanics topics: wells, spin 1/2, oscillators, and hydrogen. Throughout the course applications are woven in whenever the opportunity arises, e.g. magnetism and NMR with spin 1/2. The following semester Frontiers explores scientific principles and technological advances that make quantum science and resulting technologies different from the large scale. Frontiers covers enabling techniques from atomic, molecular, condensed matter, and particle physics, as well as advances in nanotechnology, quantum optics, and biophysics.

1:27PM B38.00010 Design of an Experimental Contemporary Physics Course which Develops the Full Experience of Scientific Research and Highlights Current Faculty Research , JAN M. YARRISON-RICE, HERBERT JAEGER, KHALID F. EID, Physics Department, Miami University, Oxford, OH 45056 — From background literature searches and reading, to conducting experiments, to presenting results and writing a journal manuscript, Miami University has revised its second-year Experimental Contemporary Physics Course, Phy293, to follow a basic research model. We examined research that faculty were conducting and chose experiments which were strongly related to understanding the ongoing research in the Department, while being based in fundamental quantum mechanics and recent 21st century physics. Experiments often had common instrumentation and data analysis techniques which allowed for grouping them into 3 basic categories: 1) Spectroscopy of gases and solids, 2) Characterization of contemporary samples, and 3) Quantized systems in electronic, magnetic and nuclear physics. These experiments also supported our secondary goal of preparing students to enter our research laboratories. At Miami, we generally have between 25-35 second year students, so the laboratory course must be managed to maintain groups of 2-3 for the best student learning outcomes. We will report on course logistics, the grouping of experiments, and methods for assessing students' learning. Having run the revised, full experimental format of Phy293 a 3rd time, we feel confident stating that this course demonstrates to students "how physics research in the 21st century is actually conducted!"

1:39PM B38.00011 Development of the Future Physicists of Florida , A. WADE, University of West Florida, C. WEATHERFORD, Florida A&M University, P. COTTLE, Florida State University, S. FANNIN, Lincoln High School, W. ROBERTS, Florida State University, M. FAUERBACH, Florida Gulf Coast University, L. PONTI, Augusta Raa Middle School, J. SEAR, The School of Arts and Sciences — We present the development of the "Future Physicists of Florida" (FPF) comprised of Florida university physics professors, middle and high school science teachers, and backed by the Florida Legislature. Our purpose is to address the lack of incoming college freshmen ready and willing to become physics majors. We will discuss the building of FPF and the development of a pipeline for middle and high school students predicted to produce the optimal number of bachelor's degrees in STEM. We will also discuss our use of community-building activities to educate the students, and their parents and teachers about the educational value of taking physics before going to college and potential careers in physics, to entertain them with fun physics related activities in order to peak their interest in physics, and to ultimately inspire the students to become physicists.

1:51PM B38.00012 A Thriving and Innovative Undergraduate Experiential Physics Program , BAHRAM ROUGHANI, Kettering University — The thriving physics program at Kettering University has experienced a three-fold increase in the number of physics majors since 2002. Our unique physics program requires students alternate between on-campus academic terms and off-campus co-op work terms on a three months rotation format to complete their degree in 4.5 years that includes summer as either school or co-op term. Students complete a minimum of five terms ($\sim$15 months) of cooperative work terms, and two terms ($\sim$6 months) of senior thesis work. The IP of the thesis work done at a co-op site belongs to the company. This has attracted co-op sponsors for our program by removing the IP concerns. The cooperative and experiential education part of our program is required for graduation, without any credits assigned to it. At the end of every co-op term students' work performance is evaluated by their co-op supervisor, which should match expected performance standards. In addition to co-op and thesis, our programs include a senior capstone design project course, concentrations within physics (Acoustics, Optics, and Materials), a required technical sequence outside physics, as well as entrepreneurship across curriculum. The success of our student securing the highest paid jobs for undergraduate physics majors in the nation plus their success in graduate studies are the main "Pull Factors" that has lead to three fold increase the physics majors since 2002.

2:03PM B38.00013 A capstone research experience for physics majors , DAVID JACKSON, Dickinson College — Dickinson College is a small liberal arts college with a thriving physics program. For years, one of the key features of our program has been a year-long senior research project that was required for each student. Unfortunately, as our number of majors increased, it became more and more difficult to supervise such a large number of senior research projects. To deal with this growing challenge, we developed a capstone research experience that involves a larger number of students working together on an independent group project. In this talk I will give a broad overview of our new senior research model and provide a few examples of projects that have been carried out over the past few years. I will also briefly describe the positive and negative aspects of this model from the perspective of faculty and students.

Monday, March 18, 2013 11:15AM - 1:51PM –

Session B39 DMP GIMS: Focus Session: Imaging & Modifying Materials Under Extreme Conditions of Radiation, Temperature, and at the Limits of Space and Time Resolution 348 -

11:15AM B39.00001 Quantifying transient dynamics in materials using time resolved *in situ* TEM , GEOFFREY CAMPBELL, Lawrence Livermore National Laboratory — The dynamic transmission electron microscope (DTEM) is a standard TEM that has been modified such that the electron beam can be operated with a single intense pulse of electrons ($> 10^9$ e^-) with a pulse duration of just 15 ns. The short pulse of electrons is created via photoemission at the microscope cathode and enables time resolved observations of *in situ* experiments. However, it can also be operated in thermionic emission mode for normal operation of the microscope for alignment and experiment setup. Additional modifications have also been made to the optical design of the condenser lens system. The *in situ* experiments currently use a second laser to initiate the dynamic response of interest in the specimen. The relative timing of the pulses from the two laser systems sets the time of the observation relative to the initiation of the event under study. The DTEM has been used to investigate a number of rapid phenomena in materials We have studied the rapid nucleation and growth at the nanoscale of crystalline phases from an initially amorphous metal alloy parent phase and in amorphous Ge. DTEM has also been used to study reactive multilayer films of Ni and Al that sustain a reaction front speed greater than 10 m/s. We have also investigated rapid solidification of nanoscale films of liquid Al-Cu alloys. This work performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:51AM B39.00002 Studying dynamic processes in liquids by TEM/STEM/DTEM , PATRICIA ABELLAN, JAMES E. EVANS, PNNL, TAYLOR J. WOEHL, KATHERINE L. JUNGJOHANN, LUCAS R. PARENT, UC -Davis, ILKE ARSLAN, PNNL, WILLIAM D. RISTENPART, UC -Davis, NIGEL D. BROWNING, PNNL, MATER. SCI. GROUP TEAM, MICROSC. GROUP TEAM, CATAL. SCI. GROUP COLLABORATION, RISTENPART RES. GROUP COLLABORATION — In order to study dynamic phenomena such as corrosion or catalysis, extreme environmental conditions must be reproduced around the specimen - these include high-temperatures, high-pressures, specific oxidizing/reducing atmospheres or a liquid environment. The use of environmental stages specifically designed to fit in any transmission electron microscope (TEM) allows us to apply the distinct capabilities of each instrument to study dynamic processes. Localized gas/fluid conditions are created around the sample and separated from the high vacuum inside the microscope using hermetically sealed windowed-cells. Advanced capabilities of these techniques include spatial resolutions of $\sim$1 Angstrom or better in aberration corrected instruments or temporal resolutions in the microsecond-nanosecond range in a dynamic TEM (DTEM). Here, unique qualities of the DTEM that benefit the *in-situ* experiments with gas/fluid environmental cells will be discussed. We also present our results with a liquid stage allowing atomic resolution imaging of nanomaterials in a colloidal suspension, core EEL spectra acquisition, continuous flow, controlled growth of nanocrystals and systematic calibration of the effect of the electron dose on silver nuclei formation.

12:03PM B39.00003 Imaging Lead Dendrite Formation and Ion Diffusion in Aqueous Solution with Scanning Transmission Electron Microscopy[1] , EDWARD WHITE, SCOTT SINGER, UCLA Department of Physics and Astronomy & CNSI, VERONICA AUGUSTYN, UCLA Department of Materials Science and Engineering & CNSI, WILLIAM HUBBARD, MATTHEW MECKLENBURG, UCLA Department of Physics and Astronomy & CNSI, BRUCE DUNN, UCLA Department of Materials Science and Engineering & CNSI, B. C. REGAN, UCLA Department of Physics and Astronomy & CNSI — Using a scanning transmission electron microscope, we image the formation of lead dendrites and the local Pb^{2+} concentration in an electrochemical cell containing a saturated solution of lead(II) nitrate. We control the morphology of the lead deposits with the rate of potential change, which can result in dendrites or compact layers. The processes are reversible and can be repeated. During lead stripping and plating the local Pb^{2+} concentration can be measured as an increase or decrease in signal intensity, respectively, as ions come into and out of solution. Quantitative digital image analysis reveals excellent correlation between changes in the Pb^{2+} concentration, the rate of lead deposition, and the current passed by the electrochemical cell. Furthermore imaging the ionic concentration as a function of time and distance from the electrode provides a measurement of the diffusion coefficient of the Pb^{2+} ion. Real-time electron microscopy of dendritic growth dynamics and the associated local ionic concentrations can provide new insight into the functional electrochemistry of batteries and related energy storage technologies.

12:15PM B39.00004 Imaging and measuring the evolution of solid density within a thermal explosion , LAURA SMILOWITZ, LANL — Explosives have been used for millennia. All materials are energetic, but high explosives have the ability to release their stored energy in a very short period of time- nanoseconds in the case of detonations. Many explosives have an as-designed behavior that is well understood and controlled. However, the off-nominal behavior, such as would occur in an accident scenario, is typically much less understood. The subject of our research has been the energy release mechanisms for secondary high explosives heated to thermal explosion. The study of thermal explosions poses several difficulties including extreme temperature, pressure, and rate of change. In addition, thermal explosions pose the difficulty of being spontaneous dynamic events with limited ability to predict the time of the event. Typically, event durations are tens of microseconds and timing jitter is tens of seconds- essentially a one in a million duty cycle. These difficulties have precluded the use of many standard laboratory diagnostics to the study of the phenomena. In the past years, we have developed diagnostics which can survive the extremes of the thermal explosion with sufficient response time and the ability to remain armed and be triggered by the onset of the spontaneous event. In addition to microsecond temporal resolution, the diagnostics need to be spatially resolved with 100 micron spatial resolution and centimeter field of view in order to capture the spatial heterogeneity of the event. Our work has focused on the important secondary high explosive PBX 9501 which is a formulation of the organic crystalline nitramine octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX). Our evolving understanding of this material has enabled us to develop a table-top x-ray imaging experiment providing millisecond time resolution with duration of minutes and sensitivity to density changes of better than 1%. This quasistatic regime provides images of material thermal expansion, phase transitions, and thermal decomposition leading to the onset of thermal ignition. A second technique provides microsecond scale time resolution with duration of milliseconds and contrast sensitivities of a few percent. This technique allows us to observe the propagation of ignition which determines the overall violence of the thermal explosion. In this talk, I will describe our current understanding of thermal explosions, and the evolution of the radiographic diagnostics that we have developed to study thermal explosions.

12:51PM B39.00005 Radiographic imaging of solidification in Al-Cu alloys , JASON COOLEY, AMY CLARKE, SETH IMHOFF, BRIAN PATTERSON, Los Alamos National Laboratory, WAH-KEAT LEE, Brookhaven National Laboratory, KAMEL FEZZAA, ALEXANDER DERIY, Argonne National Laboratory, TIM TUCKER, MARTHA BARKER, KESTER CLARKE, ROBERT FIELD, DAN THOMA, DAVID TETER, Los Alamos National Laboratory — Until the advent of third generation synchrotrons the ability to image the microstructure of metals during solidification was non-existent. Today's sources have sufficient energy and flux to perform real time radiographic imaging of solidification in thin samples with resolution sufficient to image dendrites, eutectic lamellae, and the density change across the solidification front. Feedback control of the solidification interface is also possible. We report on the radiographic imagining of Al-Cu eutectic alloys during solidification at the Argonne National Laboratory Advanced Photon Source. Cooling rates of up 10 degrees C / sec and, temperature gradients of up to 150 degrees C / cm were used to control the solidification. The samples were $\sim$ 100 microns thick and the field of view was $\sim$ 1.4 x 1.7 mm. The experimentally accessible phase space included both plane front and cellular growth regimes. The experimental resolution in the micron range was adequate to quantify cellular radii, cellular interface angles, lamellar interface angles, and lamellar spacing.

1:03PM B39.00006 Pressure-induced antiferrodistortive phase transition and phonon softening in $SrTiO_3$, SHIH-CHANG WENG, Dept of Physics, U. of Illinois at Urbana-Champaign, RUQING XU, AYMAN SAID, Advanced Photon Source, Argonne National Lab, SHIH-LIN CHANG, National Synchrotron Radiation Research Center, TAI-CHANG CHIANG, Dept of Physics, U. of Illinois at Urbana-Champaign — $SrTiO_3$, at room temperature, undergoes an antiferrodistortive transition under pressure with a critical pressure of $P_c \sim 9.6$ GPa. This transition is accompanied by a cubic–to–tetragonal structural distortion, and the same distortion can be induced at ambient pressure by lowering the sample temperature to below $T_c \sim 105$ K. The temperature-induced transition is known to involve a soft phonon at the R point in the Brillouin zone based on neutron scattering, inelastic x-ray scattering, and thermal diffuse scattering studies. The same soft mode is expected for the pressure induced transition, and we report herein the first direct measurement using inelastic x-ray scattering and a diamond-anvil pressure cell. The phonon softening behavior follows a power law and is accompanied by a central peak. The results are analyzed theoretically and correlated with those for temperature-induced transition.

1:15PM B39.00007 Femtosecond laser fabrication of micro/nano-channel array devices for parallelized fluorescence detection , BRIAN CANFIELD, WILLIAM HOFMEISTER, LLOYD DAVIS, University of Tennessee Space Institute — Cost-effective pharmaceutical drug discovery depends on increasing assay throughput while reducing reagent needs. Ultrasensitive, highly parallelized fluorescence-based platforms that incorporate a nano/micro-fluidic chip with an array of closely spaced channels would meet this need. We discuss the use of direct femtosecond laser machining to fabricate prototype fluidic chips with arrays of more than one hundred closely spaced channels. Traditional machining techniques involve overlapping focal spots from many laser pulses while scanning the substrate in order to create channels. However, this procedure is not only lengthy but may allow thermal effects to accumulate that degrade the quality of both the channel profile and surrounding substrate material. We are developing a different method for machining a line with just a single pulse, using a combination of cylindrical lenses and an aspheric lens to reshape a near-Gaussian beam into a tight line focus. Channels on the order of 1 micron wide, 5 microns deep, and nearly 2000 microns long may be made this way. We also address the critical issue of mitigating the high autofluorescence responses that arise from the creation of defects by fs-laser machining in fused silica.

1:27PM B39.00008 Bond dissociation of small molecules on the silver tip under the influence of local electric field , HAIYAN HE, Department of Physics and Astronomy, University of California, Irvine, CA 92697, MAYUKH BANIK, VARTKESS APKARIAN, Department of Chemistry, University of California, Irvine, California 92697, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697 — The manipulation of chemical bonds at metallic nano-junctions, such as at scanning tunneling junctions, and under laser irradiation is currently of great interest, motivated by both fundamental considerations and applications in nanoeletronics, nanophotonics and nanocatalysis. In this work, we systematically investigate bond formation and dissociation of small molecules (e.g., oxygen and carbon monoxide) at the junction of two silver (111) tipped surfaces, through first principles molecular dynamics simulations. The electronic structures and vibrational frequencies are a sensitive function of the gap size, and significantly modified by the local electric fields. The calculated results are compared with recent experiments. **Acknowledgement.** This work was supported by the National Science Foundation under CHE-0802913 and computing time at XSEDE.

1:39PM B39.00009 Understanding the ultrafast electron photoemission process, from simulation to experiment[1] , JENNI PORTMAN, HE ZHANG, ZHENSHENG TAO, CHONG-YU RUAN, MARTIN BERZ, PHILIP DUXBURY, Michigan State University — The ongoing efforts to develop a reliable ultrafast electron diffraction and imaging system require a stable source of photoemitted electrons and an understanding of how the properties of the generated bunch depend on the photocathode. In order to gain more understanding of this process, we combine the three-step photoemission model with N-particle electron simulations. By using the Fast Multipole Method to treat space charge effects, we are able to follow the time evolution of pulses containing over 10^6 electrons and investigate the role of laser fluence and extraction field on the total number of electrons that escape the surface. The results of these simulations are compared to experimental images of the photoemission process collected using the shadow imaging technique. We are able to show good quantitative agreement both for the number of electrons generated and the pulse parameters. We also see evidence of a virtual cathode limit, which gives an upper limit to the number of electrons that is is possible to extract. The extension of these results to various extraction fields, laser pulse shapes and photocathode material parameters, represents a very interesting future development, allowing to better optimize the materials used in electron pulse generation.

Session B40 DCMP: Surfaces, Interfaces, and Thin Films: Electronic and Magnetic Properties

349 - Michael Horn von Hoegen, Universitaet Duisburg-Essen

11:15AM B40.00001 OAM and spin structure of Cu(111) and Au(111) surface state bands , BEOMYOUNG KIM, PANJIN KIM, WONSIG JUNG, YEONGKWAN KIM, YOONYOUNG KOH, CHANGYOUNG KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, MASASHI ARITA, KENYA SHIMADA, HIROFUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima Synchrotron Radiation Center, Hiroshima University, Higashi-Hiroshima, Hiroshima 739-0046, Japan, CHOONG H. KIM, JAEJUN YU, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — We performed angle-resolved photoemission studies on Cu(111) and Au(111) surface states with circularly polarized light to investigate local orbital angular momentum (OAM) structures. Existence of OAM is confirmed, as predicted, to exist in systems with an inversion symmetry breaking. Cu(111) surface state bands are found to have chiral OAM in spite of very small spin-orbit coupling, consistent with the theoretical prediction. As for Au(111), we observe split bands for which OAM for the inner and outer bands are parallel, unlike the Bi2Se3 case. We also performed first-principles calculations and the results are found to be consistent with experimental results. Moreover, the majority of OAM is found to have $d$orbital origin while a small contribution comes from $p$orbitals. An effective Hamiltonian that incorporates the role of OAM is derived and is used to extract the spin and OAM structures. We discuss the evolution of angular momentum structures from a pure OAM system to a strongly spin-orbit-entangled state.

11:27AM B40.00002 Electronic properties of precious-metal coated W tips in STM: Role of spin-orbit coupling[1] , T. YAMASHITA, T. AKIYAMA, K. NAKAMURA, T. ITO, Mie U., S.H. RHIM, A.J. FREEMAN, Northwestern U. — Scanning tunneling microscopy (STM) has proved a versatile tool invigorating many physics at an atomic scale, where chemical identity and shape of the probe tip greatly affect resolution and sensitivity. There have been many efforts to functionalize STM tips: coating W tips with organic molecules and *3d* transition metals, which facilitate the selective imaging with enhanced tunneling current. In this work, we model W(110) tips coated by precious metals such as Au, Ag, and Pt, in which large spin-orbit coupling significantly influences the electronic structure of the STM probe. Furthermore, we argue that this spin-orbit coupling can be used as a spin detecting STM probe without additional bias switching. The stability of the W(110) apex atom for each metal coating is also discussed.

[1]Supported at N. U. by the DOE (DE-FG02-05ER45372), and at Mie U. by the Young Researcher Overseas Visits Program for Vitalizing Brain Circulation (R2214) from the Japan Society for the Promotion of Science.

11:39AM B40.00003 Ion bombardment of Ni(110) studied with inverse photoemission, LEED, and simulations , BENJAMIN YOUNG, JIM WARNER, DAVID HESKETT, University of Rhode Island — Inverse Photoemission Spectroscopy (IPES) performed on clean Ni(110) reveals an unoccupied electronic surface state ∼2eV above the Fermi level at the $\bar{Y}$ point of the surface Brillouin Zone. Ion bombardment (sputtering) of the sample creates vacancies and adatoms, which reduce the intensity of the representative state peak in IPES spectra. While the intensity of this IPES peak decreases with sputtering, well-defined diffraction spots in the surface LEED pattern give way to more diffuse ones with higher background intensity. Quantization of these permits analysis of their intensity profiles. Results of these techniques are presented for various sputtering conditions with 1keV Ne $^+$ and compared to previous results for 500eV Ar $^+$ on the same sample. Finally, we connect sputtering trends in the IPES and LEED data to Monte Carlo simulations of the sputtering process.

11:51AM B40.00004 Measurement of the Spectral Distribution of Low Energy Electrons Emitted as a Result of $M_{2,3}VV$ Auger Transitions in Cu(100) and the $N_{2,3}VV$ transition in Ag[1] , PRASAD JOGLEKAR, SUMAN SATYAL, KARTHIK SHASTRY, Dept of Physics, University of Texas at Arlington, STEVEN HULBERT, NSLS, Brookhaven National Laboratory, ALEXANDER WEISS, Dept of Physics, University of Texas at Arlington — Auger Photoelectron Coincidence Spectroscopy (APECS) was used to investigate the physics of electron emission in the Low Energy Tail (LET) of the MVV and NVV Auger spectra obtained from Cu(100) and Ag(100) surfaces, respectively. A beam of 200eV photons (180 eV in the case of Ag) was used to probe the Cu (Ag) sample. Two Cylindrical Mirror Analyzers (CMAs) were used to select the energy of electrons emitted from the sample. Auger electrons were detected in coincidence with the $3p_{3/2}$ photoemission peak in the case Cu and the 4p photoemission peak in the case of Ag. A set of coincidence measurements were made with the fixed analyzer set at a series of energies between the core and the valence band in order to obtain an estimate of the background due to the inelastic scattering of the valence band electrons. This background was then subtracted yielding a spectrum consisting only of electrons emitted as a result of the Auger transition process.

12:03PM B40.00005 Transient Exciton at Ag(111) Surface[1] , CONG WANG, XUEFENG CUI, ADAM JOHN ARGONDIZZO, University of Pittsburgh, Department of Physics & Astronomy, SEAN GARRETT-ROE, University of Pittsburgh, Department of Chemistry, HROVJE PETEK[2], University of Pittsburgh, Department of Physics & Astronomy — We investigate the surface states on Ag(111) by means of multi-photon photoemission using ultrashort laser pulses. The angle-resolved photoemission spectra at the non-resonant range are consistent with the well-known structures of Shockley states and image potential states. But when we tune the wavelength to the resonant range by two photon, the spectra is dominated by a non-dispersive feature, which should correspond to a localized state, and we assign it to transient exciton. Then we do time-resolved measurements and take Fourier Transformation with respect to the delay-axis. The dominant response of the Ag(111) sample is the driving frequency, which is unexpected because there is no one-photon resonant transition in the excitation scheme.

12:15PM B40.00006 Phonon spectra on ultrathin Pb films with scanning tunneling spectroscopy , HYOUNGDO NAM, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, Austin, Texas 78712, USA — After Blatt and Thomson's prediction [Phys. Rev. Lett. 10, 332 (1963)], several groups have reported the quantum size effect on transition temperature(Tc) as a function of thicknesses of atomically flat ultrathin Pb film. In those cases, Tc oscillation related to film thickness was attributed to oscillation of the density of states (DOS) near the Fermi energy. However, the Tc oscillation amplitude is much smaller than that derived from the DOS oscillation. One therefore would ask: What is the role of electron-phonon interaction? Also as reported by Qin, et. al. [Science 324, 1314 (2009)], when the film is only 2ML thick, the pseudomorphically strained film has lower Tc than the unstrained one, suggesting that interfacial phonons may play a role. To answer to above question, we perform layer-dependent scanning tunneling spectroscopy of Pb films on Si(111) at 2.3 K to observe the phonon related features in the tunneling spectra. Detailed analysis of thickness dependence of photon spectra will be reported.

12:27PM B40.00007 An STM and STS study on Iridium modified Si(111) Surface[1]

, NURI ONCEL, DYLAN NICHOLLS, University of North Dakota — The structure of Si(111) $\sqrt{7} \times \sqrt{7} R19.1^0 - Ir$ reconstructed surface have been investigated with the help of scanning tunneling microscopy/spectroscopy and low energy electron diffraction. We propose a model based on the experimental data. The model defines a unit cell containing one surface substitutional iridium atom centered under six silicon ad-atoms. Once the sample is annealed at 1200 °C, a low density lattice gas of these ring clusters forms on top of an impurity stabilized $'1 \times 1'$ domains. These ring clusters and $'1 \times 1'$ domains co-exist with 7×7 domains of clean Si(111) surface. The local density of states graphs measured on Si(111) $\sqrt{7} \times \sqrt{7} R19.1^0 - Ir$ reconstructed surface contains an asymmetric peak at the edge of the valence band suggesting that there is a surface state exhibiting a Rashba type spin-orbit coupling.

12:39PM B40.00008 Surface Electronic Excitations of Quantum Confined Mg Films on Si(111)[1]

, AO TENG, The University of Tennessee and Oak Ridge National Laboratory, KRZYSZTOF KEMPA, Boston College, XIAOGUANG LI, Fudan University, MUSTAFA OZER, The University of Tennessee and Oak Ridge National Laboratory, SABAN HUS, The University of Tennessee, PAUL SNIJDERS, Oak Ridge National Laboratory, GEUNSEOP LEE, Inha University, HANNO WEITERING, The University of Tennessee and Oak Ridge National Laboratory — We have investigated surface electronic excitations at atomically-smooth ultrathin Mg(0001) films on a Si(111)-7x7 substrate using high-resolution electron energy loss spectroscopy. The monopole and multipole surface plasmons of bulk Mg have their counterparts in the thin film regime. The dispersion of the monopole mode, as well as the relative intensity of the multipole mode, exhibit interesting thickness dependencies that are directly associated with quantum size effects in the Mg films. Additionally, we present the first clear observation of a photo-threshold excitation not seen at the surface of bulk Mg. Its intensity is also thickness dependent and anti-correlates with the multipole mode intensity. The results can be modeled with an effective jellium model in which the local Wigner-Seitz radius follows the thickness-dependent variation of the ground-state charge density at the surface. The results are a clear manifestation of quantum-size phenomena in the collective plasmon response of ultrathin metal films.

12:51PM B40.00009 Oscillation of conductivity in layer-by-layer growth of Bi thin film phase

, YASUNORI FUJIKAWA, Institute for Materials Research, Tohoku Univ., EIJI SAITOH, WPI-AIMR, Tohoku Univ. — Thin film growth of Bi and related compounds has been attracted much attention because of their exotic properties originating in the large spin-orbit interaction of Bi. Growth of its simple substance is known to result in the formation of a thin-film phase in the initial stage, which is taken over by the bulk growth when the coverage exceeds several monolayers (ML). [1] With typical growth conditions, this transition takes place before the completion of the thin-film layer, which tends to agglomerate to form 4-ML thick islands, making it difficult to measure the intrinsic property of the thin-film phase. In this work, Bi growth on Si(111)-7x7 has been performed in a multi-probe VT-STM system, which provides wide-ranging opportunity of kinetic control and in-situ transport measurement during the thin film growth. By tuning the kinetic condition of the growth, it becomes possible to grow the thin-film phase uniformly covering the substrate in layer-by-layer mode. In-situ transport measurement has been performed during the layer-by-layer growth of the Bi thin-film phase, distinguishing the conductivity of each growth unit. It oscillates with a period of 2 ML, which reflects the atomic structure of the thin-film phase. [1] Nagao et al., Phys. Rev. Lett. 93, 105501 (2004).

1:03PM B40.00010 ABSTRACT WITHDRAWN –

1:15PM B40.00011 Measurement of bandgap and doping effects in ultrathin MoS2 layers using scanning tunneling spectroscopy.[1]

, CHIH-PIN LU, GUOHONG LI, IVAN SKACHKO, EVA ANDREI, Department of Physics and Astronomy, Rutgers University, DEPARTMENT OF PHYSICS AND ASTRONOMY, RUTGERS UNIVERSITY TEAM — Molybdenum disulfide MoS_2, a semiconductor in the layered transition-metal dichalcogenide family of materials which is composed of weakly interacting layers held together by van der Waals interactions, offers an attractive possibility as a field effect transistor in low-power switching devices. We studied ultrathin MoS2 samples, ranging from single to several layers in thickness, that were extracted by mechanical exfoliation from the bulk material. Using a device geometry which allows varying the carrier density by gating across a 300nm insulating layer of SiO_2, together with low temperature Scanning Tunneling Microscopy and Spectroscopy, we investigated the bandgap and its dependence on doping and number of layers. For few layer samples we observe a well resolved atomic structure and a band gap of $\sim$ 1.1eV which is a little small than bulk band gap of 1.2eV. In addition we observe that electron doping shifts the Fermi energy into the conduction band. In single layer samples the measured bandgap is about $\sim$ 1.8eV in agreement with photoluminescence measurements and can change by backgate voltage.

1:27PM B40.00012 Probing the Effects of Interface Band Structure Using Ballistic Electron Emission Microscopy

, ROBERT BALSANO, VINCENT LABELLA, College of Nanoscale Science and Engineering SUNY Albany — Ballistic electron emission microscopy (BEEM) is a scanning tunneling microscopy (STM) technique that can measure transport of hot electrons through materials and interfaces with high spatial and energetic resolution. Using this technique an attenuation length for electrons in the film can be extracted from the relationship between film thickness and the number of hot electrons transmitted through the film. The behavior of the attenuation lengths of carriers with energies just above the Schottky barrier height is indicative of the interface band structure. BEEM requires an additional contact to ground the metal base layer of a metal semiconductor junction. Performing BEEM in situ with the sample fabrication greatly increases the through put for these types of measurements. This presentation will detail our data on electron transport through metals and across different interfaces and also highlight our work to develop a special silicon substrate that has the extra contact and oxide hard mask built in to enable in situ BEEM without modifications to the STM.

1:39PM B40.00013 Interface States in the metal-CdSe interfaces

, MICHELLE TOMASIK, JEFFREY GROSSMAN, MIT, VARADHARAJAN SRINIVASAN, Indian Institute of Science Education and Research — CdSe, a potential material for hybrid solar cells, has a well known reconstruction at the surface which removes the surface states. Using Density Functional Theory (DFT) we explore what happens to the now-removed surface states when CdSe is interfaced with two different metals, Al and Au. We compare and contrast this with the interfaces of a pristine unreconstructed CdSe surface with the two metals.

1:51PM B40.00014 Calculated Stability and Band Offsets for Compensated and Abrupt Polar Si/Zn(S,Se) (111) Interfaces[1] , DAVID FOSTER, GUENTER SCHNEIDER, Oregon State University — Heterovalent semiconductor interfaces, particularly in the non-symmetrizable (111) and (0001) directions, present computational challenges that must be addressed in order to predict properties such as band offsets and interface energies. We perform first principles GGA+U calculations of interface energies and band offsets for the nominally polar interfaces Si/Zn(S,Se) (111). Such wide-gap/narrow-gap heterostructures have been proposed as a possible means for altering the relaxation channel branching ratios for the decay of high energy photoelectrons (blue to UV) in favor of impact ionization (two carrier pairs from one photon). Examining configurations with one and two substitutional defect layers, we find the expected trend that compensated interfaces typically have lower energies than abrupt interfaces. The valence band offset (-0.8 ± 0.1 eV) for the lowest energy abrupt Si/ZnS interfaces agrees well with the experimentally determined value of -0.7 eV. We examine methods to address the ambiguities that arise from both finite size induced inter-interface charge transfer and the non-symmetrizability of (111) oriented supercells.

2:03PM B40.00015 Atom probe characterization of an AlN interlayer within HEMT structures grown by molecular beam epitaxy and metal-organic chemical vapor deposition , BAISHAKHI MAZUMDER, STEPHEN W. KAUN, Materials dept, University of California Santa Barbara, JING LU, STACIA KELLER, UMESH K. MISHRA, ECE dept, University of California Santa Barbara, JAMES S. SPECK, Materials dept, University of California Santa Barbara, MATERIALS DEPT, UCSB COLLABORATION, ECE DEPT, UCSB COLLABORATION — An AlN interlayer is introduced in a conventional AlGaN/GaN HEMT to enhance the density and mobility of the two dimensional electron gas (2DEG). MBE and MOCVD are two competitive and proven techniques to grow high quality AlN, but a chemical characterization technique is desired to investigate the purity of the AlN interlayer. Amongst nanoanalyzing techniques, atom probe tomography (APT) is unique for its spatial resolution and 3-D compositional images ($<$ 0.2nm) with analytical sensitivity (10appm). In this work, plasma assisted MBE(PAMBE) and MOCVD techniques were employed to grow AlGaN/AlN/GaN heterostructures. Detailed compositional data from atom probe shows that a pure AlN layer was grown by PAMBE. From Hall measurements, the carrier density (sheet resistance) was found to be 1.65 $\times$ 10^{13}cm^{-3}(188Ω/sq). The MOCVD structures do not form a pure AlN layer but that of $Al_{0.45}Ga_{0.55}N$ layer. The carrier density was found to be 1.15 $\times$ 10^{13}cm^{-3} (425 Ω/sq). This work showed that MBE technique is more suitable than MOCVD for growing pure AlN interlayers and that APT can provide valuable nano scale information for further optimization of growth structures, thereby improving device performance.

Session B41 DAMOP: Non-equilibrium Physics with Cold Atoms II 350 - Lode Pollet, Ludwig Maximilian University

11:15AM B41.00001 Time dependent impurity in ultracold fermions: orthogonality catastrophe and beyond[1] , MICHAEL KNAP, Department of Physics, Harvard University, ADITYA SHASHI, Department of Physics and Astronomy, Rice University, YUSUKE NISHIDA, Theoretical Division, Los Alamos National Laboratory, ADILET IMAMBEKOV, Department of Physics and Astronomy, Rice University, DMITRY A. ABANIN, EUGENE DEMLER, Department of Physics, Harvard University — The physics of impurities in metals and mesoscopic structures provided a deeper understanding of electrical and thermal transport properties, guided the development of new mathematical techniques, and gave useful insights into the behavior of more complicated strongly correlated materials. Ensembles of ultracold atoms offer new opportunities to study impurity physics in a well isolated, coherent setting with relatively slow time scales, that can be faithfully determined by a small number of precisely controllable parameters. In this talk, we outline a program of how to explore quantum impurity problems with ultracold atoms. In particular, we reconsider the problem of the orthogonality catastrophe (OC), which describes the dynamics of a localized impurity in a Fermi sea, and show that techniques from atomic physics, such as Ramsey pulses, spin-echo, and RF-spectroscopy, can be used to probe the OC in both time and energy domains. We present the complete solution of the OC using a combination of analytical and numerical techniques and discover new qualitative features which could not be observed in metallic systems.

11:27AM B41.00002 Topological charge pumping in a one-dimensional optical lattice , LEI WANG, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, XI DAI, Beijing National Lab for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences — A topological charge pump transfers charge in a quantized fashion. The quantization is stable against the detailed form of the pumping protocols and external noises. Such a quantum pump shares the same topological origin as the quantum Hall effect. We propose an experiment setup to realize the topological charge pumping of cold atoms in a one-dimensional optical lattice. The quantization of the pumped charge is confirmed by first-principle simulations of the dynamics of uniform and trapped systems. Quantum effects are shown to be crucial for the topological protection of the charge quantization. Finite-temperature and non-adiabatic effect on the experimental observables are discussed. Realization of such a topological charge pump servers as a firm step towards exploring topological nontrivial phases and non-equilibrium dynamics using cold atoms.

11:39AM B41.00003 Heat and spin transport in a cold atomic fermi gas[1] , HYUNGWON KIM, DAVID HUSE, Princeton University — Motivated by recent experiments measuring the spin transport in ultracold unitary atomic Fermi gases [Sommer et al., Nature (London) 472, 201 (2011); Sommer et al., New J. Phys. 13, 055009 (2011)], we explore the theory of spin and heat transport in a three-dimensional spin-polarized atomic Fermi gas. We develop estimates of spin and thermal diffusivities and discuss magnetocaloric effects, namely the the spin Seebeck and spin Peltier effects. We estimate these transport coefficients using a Boltzmann kinetic equation in the classical regime and present experimentally accessible signatures of the spin Seebeck effect. We study an exactly solvable model that illustrates the role of momentum-dependent scattering in the magnetocaloric effects.

[1]DARPA OLE Program

11:51AM B41.00004 Non-equilibrium steady states in quenched s-wave superfluids , MAXIM DZERO, Kent State University, EMIL YUZBASHYAN, Rutgers University, VICTOR GURARIE, University of Colorado Boulder — Nature and microscopic structure of the non-equilibrium many-body states in strongly interacting quantum systems remains one of most active research areas in physics. In this work, we study the steady states, which appear in a s-wave superfluid at zero temperature following a quench of the pairing strength. We use the BCS Hamiltonian which we solve exactly in the thermodynamic limit using classical integrability. We obtain a generic phase diagram of the resulting steady states for quenches corresponding to an arbitrary change of the pairing strength. We calculate single particle distribution function for each of the steady states that we find. In addition, we determine the asymptotic behavior of the pairing amplitude at long times. The experimental signatures of the steady states will also be discussed.

12:03PM B41.00005 Mean-field description of non-equilibrium dynamics of a 1D Bose gas in a weak optical lattice potential , JUAN CARRASQUILLA, Georgetown University and The Pennsylvania State University, AARON REINHARD, LAURA ZUNDEL, JEAN-FELIX RIOU, DAVID WEISS, The Pennsylvania State University, MARCOS RIGOL, Georgetown University and The Pennsylvania State University — We study the expansion of a large array of one-dimensional Bose gases subject to a weak optical lattice potential using Gutzwiller mean-field calculations aimed at describing a recent experiment with ultracold atoms. We calculate the evolution of the density profile, the quasimomentum distribution, and the density profile after a band-mapping protocol followed in experiments with ultracold atoms designed to measure the quasimomentum distribution. We find that a large fraction of bosons remains trapped at the center of the lattice. Furthermore, interactions during the expansion dramatically change the momentum distribution. Our simulations qualitatively capture most aspects of the experiment.

12:15PM B41.00006 Influence of the Amplitude in Lattice Modulation Spectroscopy , ANDREAS DIRKS, KARLIS MIKELSONS, JIM FREERICKS, Georgetown University, H.R. KRISHNAMURTHY, Indian Institute of Science — Within the Mott-insulating phase of the Hubbard model, linear-response calculations for a periodically modulated optical lattice depth clearly predict a resonance when modulated at a frequency equal to the Hubbard repulsion U. In this work we examine the effect of the amplitude of the lattice depth modulation on the threshold for excitation. Based on a recently developed strong-coupling approach to the non-equilibrium Hubbard model, we report results on the nonlinear regime and discuss effects of the amplitude as compared to the frequency for driving excitations into the upper Hubbard band.

12:27PM B41.00007 Decoherence and heating of two species fermions in optical lattices , SAUBHIK SARKAR, JOHANNES SCHACHENMAYER, STEPHAN LANGER, ANDREW J. DALEY, Department of Physics and Astronomy, University of Pittsburgh — Experiments with ultracold fermionic atoms in optical lattices present a unique way to study strongly interacting many-body quantum systems, including the Fermi-Hubbard model, in a microscopically well-understood environment. A key challenge to explore many interesting quantum phases is to reach sufficiently low temperatures and therefore it is necessary to charecterise and control competing heating processes in experiments. Incoherent scattering of light from the lasers that form the lattices can contribute significantly to the heating. We study the robustness of many-body states to this mechanism, deriving a many-body master equation for two-component fermions and investigating how the heating is influenced by choices in the atomic physics and how it depends on the parameteres in the many-body Hamiltonian.

12:39PM B41.00008 Diffusive Spin Transport of Lattice Fermions in One Dimension , ANDREW SNYDER, THEJA DE SILVA, Binghamton University — We study the long-time spin transport of fermions moving diffusively in a one dimensional lattice due to a directly introduced population imbalance and harmonic trapping potential. We combine the thermodynamic Bethe anzatz technique with the local density approximation to calculate local quantities such as magnetization and polarization. Utilizing Fick's Law, we are able to calculate the ratio of spin current to spin diffusion coefficient for both the weak and strong coupling cases that is driven by the population imbalance. We find spin current is characterized by magnetization moving from regions of low magnetization to high, with spin current being zero through insulating regions. Further, in the weak coupling limit, utilizing the linear response theory and calculating current-current correlation, we calculate local spin diffusion coefficient. The local spin diffusion coefficient shows maxima at all the insulating regions.

12:51PM B41.00009 Interaction-induced transport of ultra-cold atoms in 1D optical lattices[1] , DANIEL GRUSS, Oregon State University, CHIH-CHUN CHIEN, Los Alamos National Laboratory, MASSIMILIANO DI VENTRA, University of California, San Diego, MICHAEL ZWOLAK, Oregon State University — The study of time-dependent, many-body transport phenomena is increasingly within reach of ultra-cold atom experiments. These systems not only allow experimental emulation of solid state systems, but allow us to probe the dynamics of transport at a previously unreachable level of detail. We will discuss computational results for the dynamics of electronic/atomic transport and, in particular, simulation of interacting fermionic atoms via a micro-canonical transport formalism using approximations that go beyond mean-field. We will discuss applications of this in terms of simulating particle currents under the influence of applied current and potentials, differing spin-spin interactions, and inhomogeneous lattice impurities. Finally, we will discuss these results in the context of present-day cold atom experiments.[2]

1:03PM B41.00010 Effect of quantum fluctuations on classical motion near a separatrix in a weakly anharmonic lattice , RAFAEL HIPOLITO, Georgia Tech, VADIM OGANESYAN, CUNY College of Staten Island — We investigate the role of quantum fluctuations in the relaxation of a nonequilibrium interacting system for which the phase space curve of the corresponding classical dynamics lies near a separatrix. Such a system may be realized, for example, in a weakly interacting bosonic system if we initially excite a normal mode which lies in the low quasimomentum sector for which the the system is nearly dispersionless but of nondecay type ($\omega''(q) \lesssim 0$). As an example of such a system, we consider the case of a weakly anharmonic lattice in one dimension, where our results have some relevance to the famous Fermi-Pasta-Ulam problem. In the regime considered, we show that the classical dynamics is effectively dominated by just two normal modes which can be mapped into a single particle problem whose phase space curve lies near a separatrix. We show that for the quantum system the initial number of quanta plays the role of effective $\hbar$. Quantum fluctuations have a dramatic effect on the classical trajectory, causing the system to relax into a steady state where both the time scales associated with the relaxation and the steady state itself are strongly dependent on effective $\hbar$.

1:15PM B41.00011 Emergence of long distance pair coherence through incoherent local environmental coupling , JEAN-SEBASTIEN BERNIER, Department of Physics and Astronomy, University of British Columbia, PETER BARMETTLER, Departement de Physique Theorique, Universite de Geneve, DARIO POLETTI, Singapore University of Technology and Design, CORINNA KOLLATH, Departement de Physique Theorique, Universite de Geneve — We demonstrate that the interplay between a purely local incoherent environmental coupling, effectively heating up the system, and Hamiltonian dynamics generates quantum coherence. For a repulsively interacting fermionic lattice gas initially prepared in a Mott insulating state, coupling a noise field to the local spin density produces coherent fermionic pairs. We show that the formation of pair coherence is approximately diffusive with distance, and is experimentally observed in the pair momentum distribution as the formation of a sharp feature at the zone boundary.

1:27PM B41.00012 Dynamics of spin-1 bosons in an optical lattice , KHAN W. MAHMUD, EITE TIESINGA, Joint Quantum Institute, University of Maryland and NIST — We study spin-mixing and collapse and revival dynamics of spin-1 atoms in an optical lattice. Starting with the ferromagnetic or anti-ferromagnetic superfluid ground state - a sudden raising of the lattice depth creates a non-equilibrium state. Analysis of the oscillations in atom numbers in different spin states and the collapse and revivals in visibility reveals details about the system parameters and the initial superfluid state. For example, in situ number oscillations reveal the spin-dependent interactions, and visibility oscillations reveal the ratio of on-site and spin-dependent interactions, and thus the various scattering lengths in different channels can be determined. To study the interplay of superlfuidity and magnetism, we also examine the oscillations in various observables in the presence of an external magnetic field in the form of quadratic Zeeman energy. The frequency spectrum of the oscillations reveals the discrete energy levels and relative importance of different Fock states in the initial superfluid and magnetic states.

1:39PM B41.00013 Fluctuation-induced dissipation in non-equilibrium moving systems , MOHAMMAD MAGHREBI, MIT, RAMIN GOLESTANIAN, Oxford University, ROBERT JAFFE, MEHRAN KARDAR, MIT — Quantum fluctuations in moving systems lead to nontrivial effects such as dissipation and radiation. We consider moving bodies—a single rotating object or multiple objects in relative motion—and derive the frictional force by using techniques from non-equilibrium statistical physics as well as quantum optics. The radiation to the environment is obtained as a general expression in terms of the scattering matrix which is a powerful analytical tool. We apply our general formulas to several examples of systems out of equilibrium due to their motion.

1:51PM B41.00014 Dynamical Entanglement Growth and Measurement with Cold Atoms or Ions , JOHANNES SCHACHENMAYER, University of Pittsburgh, University of Innsbruck, and Institute for Quantum Optics and Quantum Information, Innsbruck, HANNES PICHLER, PETER ZOLLER, BEN LANYON, University of Innsbruck, and Institute for Quantum Optics and Quantum Information, Innsbruck, ANDREW J. DALEY, University of Pittsburgh — Systems of cold atoms in optical lattices or a string of ions in a linear trap offer the possibility to experimentally study non-equilibrium dynamics of 1D many-body quantum systems with interactions of varying range in a controlled environment. Entanglement is a basic feature of these systems, and the increase of the entanglement entropy between different blocks of a many-body state as a function of time determines whether the long-time evolution of the system can be efficiently simulated on a classical computer. Correspondingly, states with large-scale entanglement offer regimes where quantum simulators could be used to outperform classical simulation. Thus, there is a great interest to produce large-scale entanglement in these types of experiments. Here we present analytical and numerical results on the entanglement entropy growth behavior in 1D lattice systems after a sudden quench of a model parameter, and the dependence of this growth on the range of the interactions. Furthermore, we present how bipartite Rényi entropies can be measured solely by using tunnel couplings and local measurements, tools which are both available in recent experiments with bosons in optical lattices.

2:03PM B41.00015 Non-equilibrium scaling, response and coarsening in the quantum large N vector model[1] , ANUSHYA CHANDRAN, VEDIKA KHEMANI, ARUN NANDURI, S. S. GUBSER, S. L. SONDHI, Princeton University — The out-of-equilibrium dynamics of a quantum system that is suddenly or slowly driven in the vicinity of critical point is conjectured to be universal and can be described in a scaling framework. The long time tails of scaling functions for a quench from the disordered to the ordered phase are of particular experimental interest. We theoretically investigate this in the $O(N)$ vector model as $N \to \infty$ for different spatial dimensions. We demonstrate that the quartic operator that is irrelevant to the equilibrium physics above the upper critical dimension is dangerously irrelevant to the long time dynamics in the scaling limit. We also observe a quantum analogue of the classical process of coarsening in which a correlation length diverges at long times in the thermodynamic limit. Suitably defined linear response measurements offer the tantalizing possibility of directly observing the non-equilibrium scaling functions; we explore these in classical models and Chern insulators as well.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B42 FIAP: Quantum Hall Effect: Edges, Interferometry, & nu = 5/2 Hilton Baltimore Holiday Ballroom 3 - Sriram Ganeshan, University of Maryland

11:15AM B42.00001 Spin and charge distribution symmetry dependence of stripe phases in two-dimensional electron systems confined to wide quantum wells , YANG LIU, DOBROMIR KAMBUROV, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Dept Electrical Engineering, Princeton University — When a spin-split $N \leq 2$ Landau level is half filled, the two-dimensional electron system (2DES) is expected to break the rotational symmetry by forming a unidirectional charge density wave, the so-called stripe phase. The stripes are known to rotate from the "normal" ([110]) direction to the "abnormal" ([1$\bar{1}$0]) direction when the 2DES density is raised above a critical density. We report a study of the evolution of the stripe phase orientation near Landau level filling factors $\nu = 13/2$ and 15/2 when E_F lies in the two, spin-split, $N = 2$ Landau levels of the symmetric subband (the S2↑ and S2↓ levels) while the $N = 0$ Landau levels of the antisymmetric subband are fully occupied. We find that when E_F lies in S2↓ the stripes are always formed along the "normal" direction. But, when E_F lies in the S2↑ level, the orientation of the stripes can rotate to be along the "abnormal" direction at high densities. At a density where the stripe phase at $\nu = 13/2$ is along the "abnormal" direction, we can rotate it back to the normal direction by making the charge distribution asymmetric while keeping the density fixed.

11:27AM B42.00002 Distinguishing Particle-Hole Conjugated Fractional Quantum Hall States Using Quantum Dot Mediated Edge Transport , HSIN-HUA LAI, National High Magnetic Field Laboratory, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University — We first study the edge transport in the $\nu = 1/3$ and $\nu = 2/3$ Fractional Quantum Hall bars mediated by a $\nu = 1$ quantum dot. We conclude that the $\nu = 1/3$ and $\nu = 2/3$ systems show different $1/3$-charged quasi-particle tunneling exponents. When the quantum dot becomes large, its edge states join those of the original Hall bar to reconstruct the edge state configurations. In the disorder-irrelevant phase, the two-terminal conductance of the original $\nu = 1/3$ system vanishes at zero temperature, while that of the $\nu = 2/3$ case is finite. In the disorder-dominated phase, the two-terminal conductance of $\nu = 1/3$ system is $(1/5)e^2/h$ while that of $\nu = 2/3$ system is $(1/2)e^2/h$. We further apply the same idea to the $\nu = 5/2$ system which realizes either Pfaffian or anti-Pfaffian states. By engineering a central $\nu = 3$ quantum dot in the $\nu = 5/2$ Hall bar, we study the charged quasi-particle tunneling effects and conclude that the Pfaffian and anti-Pfaffian states show different quasi-particle tunneling exponents. If the quantum dot is large enough for its edge states joining with those of the original Hall bar, the two-terminal conductance of Pfaffian state can be $G_{Pf} \to 2e^2/h$ while that of anti-Pfaffian state is higher, $G_{aPf} > 2e^2/h$.

11:39AM B42.00003 Intrinsic edge dipole moment of incompressible fractional quantum Hall ground states[1] , YEJE PARK, F.D.M. HALDANE, Princeton University — The edges of incompressible fractional quantum Hall (FQH) fluids have a characteristic dipole moment related to their Hall viscosity, which can be split into two separate contributions: a (trivial) contribution from the Landau orbit (common to all FQH fluids in the same Landau level, and a (non-trivial) guiding-center contribution that depends on the FQH state. Using the model wave functions for (fermonic and bosonic) Laughlin states ($\nu = 1/2$, 1/3, 1/4), and Moore-Read states ($\nu = 2/2$, 2/4) expressed as Jack polynomials, we obtained the guiding-center occupation number distributions $n(k)$ of "Landau-gauge" basis states with k near the edge "$\nu^{-1}k_F$" of a FQH fluid in cylindrical geometries of various circumferences, and verified the "Luttinger" and "edge-dipole" sum rule. The edge-dipole moments of the FQH fluids were expressed as a combination of quantized quantities: electric charge e, "guiding center spin" s and number of fluxes per "composite boson" q in [F. D. M. Haldane, arXiv:0906.1854 (2009)]. Our work provides a numerical verification of the prediction. The edge dipole experiences a force due to the gradient of electric field perpendicular to the edge, and the force is balanced by stress from the "guiding center Hall viscosity".

[1]Supported by DOE DE-SC0002140

11:51AM B42.00004 FQHE interferometer in strong tunneling regime: The role of compactness of edge fields , SRIRAM GANESHAN, University of Maryland, College Park, ALEXANDER ABANOV, DMITRI AVERIN, Stony Brook University — The defining feature of quantum Hall states is the existence of topologically protected massless edge states. These states are believed to be effectively described by a theory of chiral bosons also known as the one-dimensional chiral Luttinger Liquid. The tunneling experiments provide one of the natural ways to probe these edge states. In this work, we consider multiple-point tunneling in the interferometers formed between edges of electron liquids with in general different filling factors in the regime of the Fractional Quantum Hall effect (FQHE). We derive an effective matrix Caldeira-Leggett model for the multiple tunneling contacts connecting the chiral single-mode FQHE edges. We show that the compactness of the Wen-Fröhlich chiral boson fields describing the FQHE edge modes plays a crucial role in defining strong (quasiparticle) tunneling regime. We also show that the compactness condition results in electron periodicity for quasiparticle tunneling with respect to adiabatic variation of flux.

12:03PM B42.00005 Edge properties of principal fractional quantum Hall states in the cylinder geometry , PAUL SOULE, THIERRY JOLICOEUR, Univ of Paris - Sud 11 CNRS — We study fractional quantum Hall states in the cylinder geometry with open boundaries. We focus on principal fermionic $\nu = 1/3$ and bosonic $\nu = 1/2$ fractions in the case of hard-core interactions. The gap behavior as a function of the cylinder radius is analyzed. By adding enough orbitals to allow for edge modes, we show that it is possible to measure the Luttinger parameter of the nonchiral liquid formed by the combination of the two counterpropagating edges when we add a small confining potential. Although we measure a Luttinger exponent consistent with the chiral Luttinger theory prediction for the full hard-core interaction, the exponent remains nontrivial in the Tao-Thouless limit as well as for simple truncated states that can be constructed on the cylinder. If the radius of the cylinder is taken to infinity, the problem becomes a Tonks-Girardeau one-dimensional interacting gas in Fermi and Bose cases. Finally, we show that the Tao-Thouless and truncated states have an edge electron propagator, which decays spatially with a Fermi-liquid exponent, even if the energy spectrum can still be described by a nontrivial Luttinger parameter.

12:15PM B42.00006 Edge spin excitations and reconstructions of spin-polarized and spin-unpolarized quantum Hall liquids , YUHUI ZHANG, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University — We study the effect of electron-electron interaction on the charge and spin structures at the edge of quantum Hall liquids, under three different kinds of confining potentials. Our exact diagonalization calculation for small systems indicates that the low energy excitations of $\nu = 1$ ferromagnetic state are bosonic edge spin waves. Instabilities of $\nu = 1$ ferromagnetic state with altering confinement strength result from the softening of these edge spin waves, and formation of edge spin textures. In $\nu \lesssim 2$ regime, exact diagonalization on edge electron systems indicates that compact Hartree-Fock states with different total spin always become ground states in some regions of parameter space, and the ground states appear in between two compact states are their edge spin waves. The initial $\nu = 2$ instability is toward the compact state with total spin 1. Larger systems are studied using a microscopic trial wave functions, and some quantitative predictions on the edge instabilities for a certain type of confining potential are reached in the thermodynamic limit. In fractional quantum Hall regime, $\nu = 1/3$ polarized and $\nu = 2/3$, $2/5$ unpolarized states' low energy edge states are also obtained by exact diagonalization for small systems.

12:27PM B42.00007 Quantum Hall Line Junctions under In-Plane Magnetic Fields , P. JIANG, National Taiwan Normal University, I. YANG, University of Chicago, W.-H. WANG, S.-C. YU, National Taiwan Normal University, L.N. PFEIFFER, K.W. WEST, K.W. BALDWIN, Lucent Technologies, W. KANG, University of Chicago — Study of tunneling between two antiparallel quantum Hall edge states under the influence of in-plane magnetic field will be presented. Previously quantum Hall line junctions were shown to have highly correlated behavior consistent with formation of coupled Luttinger liquids. Power-law energy dependence observed in the tunneling conductance supports realization of the Luttinger-liquid correlation of the coupled edge states. Under the presence of in-plane magnetic field, the tunnel spectrum is found to evolve with emergence of novel features. Systematic evolution of these features are studied with in-plane fields either parallel or perpendicular to the line junction. We discuss these results in terms of the presence of additional low-excitation modes detected through momentum-resolved tunneling.

12:39PM B42.00008 X-ray edge singularity in the visibility of the Aharonov-Bohm oscillations in a quantum Hall interferometer , IURII CHERNII, IVAN LEVKIVSKYI, EUGENE SUKHORUKOV, University if Geneva — We consider a quantum dot strongly interacting with several quantum Hall edge channels. One of the channels is an arm of an electronic Mach Zender interferometer, and another one is coupled to the dot via weak tunneling. Fluctuations of the charge in the quantum dot lead to dephasing of the interfering electrons. Such processes have been studied extensively, however the effects of backaction were either not considered at all, or taken into account perturbatively in the interaction strength. We show that there are regimes where tunneling itself is mainly induced by the non-equilibrium noise in the interferometer at finite bias. Importantly, this backaction effect is non-perturbative and can not be neglected. The problem of tunneling induced by the non-equilibrium noise demonstrates equivalence to the X-Ray edge singularity problem, and the tunneling rates are found to be a power-low functions of the detuning between the dot energy level and the Fermi energy. Consequently, the visibility of the interference pattern shows a crossover between the two lorentzian-type functions with different effective temperatures at small and large energies. The two temperatures are proportional to the noise temperature with a coefficients depending on the interaction strength.

12:51PM B42.00009 Backaction Dephasing Induced by a Quantum Dot Detector , TOSHIHIRO KUBO, YASUHIRO TOKURA, University of Tsukuba — We theoretically investigate the backaction dephasing by a quantum dot detector (QDD) that couples to the quantum dot embedded in one arm of Aharonov-Bohm (AB) interferometer. We employ the nonequilibrium second-order perturbation theory and provide an analytical expression for the backaction dephasing rate, which characterizes the disturbance induced by coupling with an environment containing QDD. We show that the origin of backaction dephasing is a charge noise of QDD. In the linear transport regime through a QDD, this backaction dephasing induced by charge noise can be explained as a relaxation by an inelastic electron-electron scattering within the framework of Fermi liquid theory. In the low bias voltage regime, the increase or decrease of dephasing rate depends on the QDD energy level, the linewidth functions, and how to apply the bias voltage. Unlike quantum point contact detector, the dephasing rate would be insensitive to the bias voltage in a high bias voltage regime since the charge noise of a QDD is saturated. Moreover, such behaviors can be verified in terms of the visibility of AB oscillations by changing the bias voltage across the QDD.

1:03PM B42.00010 Visibility recovery by strong interaction in an electronic Mach-Zehnder interferometer , SOO-YONG LEE, HYUN-WOO LEE, POSTECH, HEUNG-SUN SIM, KAIST — We study the evolution of a single-electron packet of Lorentzian shape along an edge of the integer quantum Hall regime or in a Mach-Zehnder interferometer, considering a capacitive Coulomb interaction and using a bosonization approach. When the packet propagates along a chiral quantum Hall edge, we find that its electron density profile becomes more distorted from Lorentzian due to the generation of electron-hole excitations, as the interaction strength increases yet stays in a weak interaction regime. However, as the interaction strength becomes larger and enters a strong interaction regime, the distortion becomes weaker and eventually the Lorentzian packet shape is recovered. The recovery of the packet shape leads to an interesting feature of the interference visibility of the symmetric Mach-Zehnder interferometer whose two arms have the same interaction strength. As the interaction strength increases, the visibility decreases from the maximum value in the weak interaction regime, and then increases to the maximum value in the strong interaction regime. We argue that this counter-intuitive result also occurs under other types of interactions.

1:15PM B42.00011 Coupling a quantum Hall droplet to a microwave transmission line , JENNIFER CANO, UCSB, CHETAN NAYAK, UCSB and Microsoft Station Q — Electromagnetically coupling a quantum Hall droplet to a microwave transmission line establishes a realm of new experiments that might provide a more direct measurement of certain physical properties. Specifically, peaks in the absorption spectrum would occur at multiples of the ratio of the edge velocity to the perimeter of the droplet, potentially offering a more precise measurement of the velocity of edge modes than the few existing measurements. If the droplet is at filling fraction 5/2 and deformed to allowing tunneling between edges, additional peaks would emerge corresponding to the velocity of the neutral mode, which has never before been measured. In addition, the set-up could be used as an interferometer in fractional quantum Hall states by observing shifts in the magnitude of the absorption peak at fixed frequency as the number of quasiparticles is varied via the magnetic field. This would be complementary to existing interferometry measurements of fractional statistics.

1:27PM B42.00012 Interactions in quantum Hall edge channels at filling fraction 2[1] , PASCAL DEGIOVANNI, CNRS / ENS Lyon, ERWANN BOCQUILLON, VINCENT FREULON, Laboratoire Pierre Aigrain, ENS Paris, CHARLES GRENIER, Centre de Physique Théorique, Ecole Polytechnique, JEAN-MARC BERROIR, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain, ENS Paris, ANTONELLA CAVANNA, YONG JIN, CNRS / Laboratoire de Photonique et de Nanostructures, GWENDAL FÈVE, Laboratoire Pierre Aigrain, ENS Paris — Coulomb interactions play a major role in one dimensional electronic transport. They modify the nature of the elementary excitations from Landau quasiparticles in higher dimensions to collective excitations in 1D. We report here on the direct observation of the collective neutral and charge modes of the two chiral co-propagating edge channels of opposite spins of the quantum Hall effect at filling factor $\nu = 2$. Generating a charge density wave at frequency f in the outer channel, we measure the current induced by inter-channel Coulomb interaction in the inner channel after a 3 microns propagation length. Varying the driving frequency from 0.7 to 11 GHz, we observe damped oscillations in the induced current that results from the phase shift between the fast charge and slow neutral eigenmodes. Measuring the dispersion relation and dissipation of the neutral mode from provides quantitative information on the scattering of quantum edge magnetoplasmons. We will then comment on the consequences of these results on quasi-particle relaxation and decoherence in the $\nu = 2$ quantum Hall edge channel system.

[1]ANR Grant 1shot (ANR-2010-BLANC-0412)

1:39PM B42.00013 Coherent Terahertz Magneto-Spectroscopy of High-Mobility Two-Dimensional Electron Gases , QI ZHANG, TAKASHI ARIKAWA, Rice Univerisy, WEI PAN, JOHN RENO, Sandia National Laboratory, JOHN WATSON, MICHAEL MANFRA, Purdue University, JUNICHIRO KONO, Rice Univerisy, RICE UNIVERSITY TEAM, SANDIA NATIONAL LABORATORY COLLABORATION, PURDUE UNIVERSITY COLLABORATION — Landau-quantized high-mobility two-dimensional electron gases (2DEG) in GaAs quantum wells provide an ideal platform for studying and controlling the coherence of many-electron states. Here, we study the coherent dynamics of cyclotron resonance (CR) in a 2DEGin the terahertz range. It is well known that Kohn's theorem protects the CR frequency from the influence of electron-electron interactions, but how the coherence of CR decays via electron-electron interactions is an open question. Since the 1980s, studies have focused on CR decoherence time measurements, primarily using incoherent far-infrared spectroscopy, which fails to obtain the true CR linewidth due to the 'saturation effect' in high-mobility systems. By using coherent time-domain magneto-terahertz spectroscopy, we have systematically studied the CR decoherence time in an ultrahigh-mobility 2DEG as a function of both temperature and magnetic field. These results show a clear saturation of the CR decoherence time at low temperature, which decreases monotonically with increasing magnetic field. No filling-factor-dependent oscillations of CR dephasing time have been observed. Possible CR decoherence mechanisms will be discussed in light of these new findings.

1:51PM B42.00014 Influence of Device Geometry on Tunneling in ν=5/2 Quantum Hall Liquid[1] , GUANG YANG, DMITRI FELDMAN, Brown University — Two recent experiments [1,2] measured the temperature and voltage dependence of the tunneling current through a constriction in the ν=5/2 quantum Hall liquid. The results led to conflicting conclusions about the nature of the 5/2 quantum Hall state. The results of Ref. [1] were interpreted as supporting the anti-Pfaffian non-Abelian state while the results of Ref. [2] suggested that the Abelian 331 state was more likely. Several different constriction geometries were used in Refs. [1,2]. We argue that in some of those geometries there is significant unscreened electrostatic interaction between segments of the quantum Hall edge on the different sides of the constriction. The Coulomb interaction affects the tunneling current. After the Coulomb corrections are taken into account, the results from all geometries agree and support the same 5/2 state.

2:03PM B42.00015 Anomalous density dependence of the activation gap of ν =5/2 fractional quantum Hall state at extremely large Landau level mixing , NODAR SAMKHARADZE, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University, GABOR CSATHY, Purdue University — We have conducted a study of the density dependence of ν =5/2 fractional quantum Hall state (FQHS) in the regime of extremely low densities, down to n=4.9x10^10 cm^-2. In the density range accessed in our sample, the Landau level mixing parameter κ spans the so far unexplored range 2.52<κ <2.82. Here we observe an anomalous dependence of the activation gap of ν =5/2 FQHS on the carrier density. We discuss the possible origins of this unexpected behavior. N.S. and G.C. were supported by the NSF grant DMR-0907172 and DMR-1207375. K. West and L. Pfeiffer acknowledge the support of the Princeton NSF-MRSEC and the Moore Foundation.

Session B43 DCP: Focus Session: Multiscale modeling–Coarse-graining in Space and Time II

Hilton Baltimore Holiday Ballroom 2 - Garegin Papoian, University of Maryland at College Park

11:15AM B43.00001 Multiscale simulations of ion channel opening and closing provide insights into the molecular mechanisms of gating , GERHARD HUMMER[1], National Institutes of Health — We develop and implement a multiscale molecular simulation approach to study the opening and closing of a ligand-gated ion channel at atomic resolution. Ligand-gated channels are essential in biological signaling pathways that range from chemical sensing in bacteria to the firing of neurons in humans. On the basis of recently determined crystal structures and with the help of multiscale molecular simulations we study the conformational changes associated with GLIC ion channel gating transition. Starting from a coarse-grained transition pathway constructed on the basis of a multistate elastic network model, we perform string-method molecular dynamics simulations to refine the pathway at full atomic resolution. We find that the channel closes in an iris-like fashion as a result of a two-stage tilting of the pore lining helices. Water plays a central role in the gating transition. We find that the hydrophobic gate of the pore undergoes highly cooperative transitions between a densely filled and an empty state. The subtle tilting of the helices shifts the balance to the dry state, in which a 1.5 nm long hydrophobic stretch of the pore completely empties. By calculating the ionic conductance and the underlying free energy surface, we quantitatively demonstrate that this drying of the hydrophobic constriction, not sterics, is the major determinant of ion conductivity in the GLIC pentameric ion channel.

[1]I thank Prof. Fangqiang Zhu (Department of Physics, Indiana University-Purdue University, Indiana) who carried out the bulk of this work.

11:51AM B43.00002 Multiscale modeling of macromolecular dynamics , CECILIA CLEMENTI, Rice University, Department of Chemistry — The understanding of emerging collective behaviors in biomolecular complexes represents a major challenge in modern biophysics. As a first step toward the study of such processes we have applied multi-resolution nonlinear dimensionality reduction and diffusion analysis to obtain reliable low-dimensional representations and models for the dynamics of apparently high-dimensional complex systems such as proteins in a biological environment. The results clearly show that the proposed methods can efficiently find low dimensional representations of complex processes such as protein folding, and suggest strategies to simplify significantly the study of such processes.

12:27PM B43.00003 Transferability of Coarse Grained Models: a Challenge for Simulation of Phase Transitions or Phase Separation Processes , CHRISTINE PETER, Max Planck Institute for Polymer Research, Mainz — Upon developing a coarse grained (CG) model, representability and transferability limitations are a problem that is inherent to the process of reducing the number of degrees of freedom. In this context, representability refers to the question which structural or thermodynamic properties of a higher resolution reference are reproduced by the CG model, and transferability refers to the question to which extent a CG model is applicable at a state-point that differs from the one where it was parametrized. This is naturally a highly relevant problem in simulations that involve phase transitions or structure formation processes driven by phase separation, for example in liquid crystalline systems or in biomolecular aggregation. I will show with a few examples how one can achieve and rationalize state-point transferability for CG models that have been parameterized in a bottom-up procedure from atomistic reference simulations, for example by choosing an appropriate reference state point.

1:03PM B43.00004 Mesoscopic Dynamics of Biopolymers and Protein Molecular Machines[1] , RAYMOND KAPRAL[2], University of Toronto — The dynamics of biopolymers in solution and in crowded molecular environments, which mimic some features of the interior of a biochemical cell, will be discussed. In particular, the dynamics of protein machines that utilize chemical energy to effect cyclic conformational changes to carry out their catalytic functions will be described. The investigation of the dynamics of such complex systems requires knowledge of the time evolution on physically relevant long distance and time scales. This often necessitates a coarse grained or mesoscopic treatment of the dynamics. A hybrid particle-based mesoscopic dynamical method, which combines molecular dynamics for a coarse-grain model of the proteins with multiparticle collision dynamics for the solvent, will be described and utilized to study the dynamics of such systems. See, C. Echeverria, Y. Togashi, A. S. Mikhailov, and R. Kapral, Phys. Chem. Chem. Phys 13, 10527 (2011); C. Echeverria and R. Kapral, Phys. Chem. Chem. Phys., 14, 6755 (2012); J. M. Schofield, P. Inder and R. Kapral, J. Chem. Phys. 136, 205101 (2012).

1:39PM B43.00005 Multiscale Modeling of Deformation of Glassy Polymers , THOMAS ROSCH, JOHN BRENNAN, SERGEI IZVEKOV, JAN ANDZELM, Army Research Lab — We examine the ability of chemically informed coarse-grained (CG) models to quantitatively describe correct mechanical properties of glassy polymer systems. The force-matching and the structure-matching procedures were used to obtain CG potentials at different levels of resolution. Equilibrium molecular dynamics simulations of amorphous polymers modeled at the all-atom level provided the necessary reference data. This work explores what characteristics are necessary for quantitative agreement of stress-strain curves between scales. For large coarse-graining (17 atoms per CG site of polystyrene) the force-matching procedure produces a potential that does not contain enough attraction to predict the correct elastic properties. Systematic methods were employed to match mechanical properties and their effects on polymer structure were examined. Higher resolution coarse-graining (5-11 atoms per CG site) is better able to reproduce atomistic mechanical data.

1:51PM B43.00006 Force fields for describing the solution-phase synthesis of shape-selective metal nanoparticles , YA ZHOU, The Pennsylvania State University, WISSAM AL-SAIDI, University of Pittsburgh, KRISTEN FICHTHORN, The Pennsylvania State University — Polyvinylpyrrolidone (PVP) and polyethylene oxide (PEO) are structure-directing agents that exhibit different performance in the polyol synthesis of Ag nanostructures. The success of these structure-directing agents in selective nanostructure synthesis is often attributed to their selective binding to Ag(100) facets. We use first-principles, density-functional theory (DFT) calculations in a vacuum environment to show that PVP has a stronger preference to bind to Ag(100) than to Ag(111), whereas PEO exhibits much weaker selectivity. To understand the role of solvent in the surface-sensitive binding, we develop classical force fields to describe the interactions of the structure-directing (PVP and PEO) and solvent (ethylene glycol) molecules with various Ag substrates. We parameterize the force fields through force-and-energy matching to DFT results using simulated annealing. We validate the force fields by comparisons to DFT and experimental binding energies. Our force fields reproduce the surface-sensitive binding predicted by DFT calculations. Molecular dynamics simulations based on these force fields can be used to reveal the role of solvent, polymer chain length, and polymer concentration in the selective synthesis of Ag nanostructures.

2:03PM B43.00007 Enhancing and reversing the electric field at liquid/liquid interfaces , YUFEI JING, GUILLERMO GUERRERO GARCIA, MONICA OLVERA DE LA CRUZ, Department of Materials Science, Northwestern University, Evanston, IL 60208, USA — The ion distribution at the interface between two immiscible electrolyte solutions determines the macroscopic properties of these liquid interfaces. The classical Poisson-Boltzmann theory has been widely used to describe it, even though it neglects the polarization and ion correlations typical of these ionic solutions. Here, we provide an enhanced description of a liquid/liquid interface in the presence of an electric field from first principles–that is, without needing any fitting parameter–including ion correlations, image charges and realistic ion-sizes in Monte Carlo simulations. Our data agree well with experimental excess surface tension measurements for a wide range of electrolyte concentrations, contrasting with the results of the classical Poisson-Boltzmann theory. More importantly, we observe that, in the vicinity of the point of zero charge, the electric field can increase significantly in strength near the liquid interface, or it can even reverse locally, at high salt concentration.

Monday, March 18, 2013 11:15AM - 2:15PM –

Session B44 DBIO GSNP: Focus Session: Population and Evolutionary Dynamics II Hilton Baltimore Holiday Ballroom 1 - Uwe Tauber, Virginia Tech

11:15AM B44.00001 The statistics of genetic diversity in rapidly adapting populations. , MICHAEL DESAI, Harvard University — Evolutionary adaptation is driven by the accumulation of beneficial mutations, but the sequence-level dynamics of this process are poorly understood. The traditional view is that adaptation is dominated by rare beneficial "driver" mutations that occur sporadically and then rapidly increase in frequency until they fix (a "selective sweep"). Yet in microbial populations, multiple beneficial mutations are often present simultaneously. Selection cannot act on each mutation independently, but only on linked combinations. This means that the fate of any mutation depends on a complex interplay between its own fitness effect, the genomic background in which it arises, and the rest of the sequence variation in the population. The balance between these factors determines which mutations fix, the patterns of sequence diversity within populations, and the degree to which evolution in replicate populations will follow parallel (or divergent) trajectories at the sequence level. Earlier work has uncovered signatures of these effects, but the dynamics of genomic sequence evolution in adapting microbial populations have not yet been directly observed. In this talk, I will describe how full-genome whole-population sequencing can be used to provide a detailed view of these dynamics at high temporal resolution over 1000 generations in 40 adapting *Saccharomyces cerevisiae* populations. This data shows how patterns of sequence evolution are driven by a balance between chance interference and hitchhiking effects, which increase stochastic variation in evolutionary outcomes, and the deterministic action of selection on individual mutations, which favors parallel solutions in replicate populations.

11:51AM B44.00002 Metastability and Anomalous Fixation in Evolutionary Games on Scale-Free Networks , MICHAEL ASSAF, Hebrew University of Jerusalem, MAURO MOBILIA, University of Leeds — We study the influence of complex graphs on the metastability and fixation properties of a set of evolutionary processes. In the framework of evolutionary game theory, where the fitness and selection are frequency dependent and vary with the population composition, we analyze the dynamics of snowdrift games (characterized by a long-lived metastable coexistence state) on scale-free networks. Using an effective diffusion theory valid in the weak selection limit, we demonstrate how the scale-free structure affects the system's metastable state and leads to anomalous fixation. In particular, we analytically and numerically show that the probability and mean time to fixation are characterized by stretched-exponential behaviors with exponents depending on the network's degree distribution.

M. Assaf* and M. Mobilia*, PRL 109, 188701 (2012) (* - equal contribution)

12:03PM B44.00003 Unveiling adaptation using high-resolution lineage tracking , JAMIE BLUNDELL, SASHA LEVY, DANIEL FISHER, DMITRI PETROV, GAVIN SHERLOCK, Stanford University — Human diseases such as cancer and microbial infections are adaptive processes inside the human body with enormous population sizes: between $10^6 - 10^{12}$ cells. In spite of this our understanding of adaptation in large populations is limited. The key problem is the difficulty in identifying anything more than a handful of rare, large-effect beneficial mutations. The development and use of molecular barcodes allows us to uniquely tag hundreds of thousands of cells and enable us to track tens of thousands of adaptive mutations in large yeast populations. We use this system to test some of the key theories on which our understanding of adaptation in large populations is based. We (i) measure the fitness distribution in an evolving population at different times, (ii) identify when an appreciable fraction of clones in the population have at most a single adaptive mutation and isolate a large number of clones with independent single adaptive mutations, and (iii) use this clone collection to determine the distribution of fitness effects of single beneficial mutations.

12:15PM B44.00004 Evolutionary dynamics of fluctuating populations with strong mutualism , THIPARAT CHOTIBUT, DAVID NELSON, Department of Physics, Harvard University — Evolutionary game theory with finite interacting populations is receiving increased attention, including subtle phenomena associated with number fluctuations, i.e., "genetic drift." Models of cooperation and competition often utilize a simplified Moran model, with a strictly fixed total population size. We explore a more general evolutionary model with *independent* fluctuations in the numbers of two distinct species [1], in a regime characterized by "strong mutualism." The model has two absorbing states, each corresponding to fixation of one of the two species, and allows exploration of the interplay between growth, competition, and mutualism. When mutualism is favored, number fluctuations eventually drive the system away from a stable fixed point, characterized by cooperation, to one of the absorbing states. Well-mixed populations will thus be taken over by a single species in a finite time, despite the bias towards cooperation. We calculate both the fixation probability and the mean fixation time as a function of the initial conditions and carrying capacities in the strong mutualism regime, using the method of matched asymptotic expansions. Our results are compared to computer simulations.[1] S. Pigolotti et al., http://arxiv.org/abs/1208.4973

12:27PM B44.00005 Range expansions favor the evolution of cooperation in an experimental microbial metapopulation , MANOSHI DATTA, KIRILL KOROLEV, Massachusetts Institute of Technology, IVANA CVIJOVIC, University of Cambridge, CARMEL DUDLEY, JEFF GORE, Massachusetts Institute of Technology — Natural populations frequently undergo range expansions in response to changes in the environment. Recent work suggests that range expansions can have a strong effect on evolution, even leading to the fixation of deleterious alleles that would normally be outcompeted in the absence of migration. However, little is known about how range expansions might influence alleles under frequency- or density-dependent selection. Moreover, there is very little experimental evidence to complement existing theory, since expanding populations are difficult to study in nature. In this study, we have used a yeast experimental system to explore the effect of range expansions on the evolution of cooperative behaviors, which commonly display frequency- and density-dependent selection and are widespread in nature. We found that range expansions favor the evolution of cooperation in two ways: (1) through the enrichment of cooperators at the front of the expanding population, and (2) by allowing cooperators to "outrun" an invading wave of defectors. In this system, cooperation is enhanced through the coupling of population ecology and evolutionary dynamics in expanding populations, providing experimental evidence for a novel mechanism through which cooperative behaviors could be maintained in nature.

12:39PM B44.00006 Slower recovery in space before collapse of connected populations , LEI DAI, KIRILL KOROLEV, JEFF GORE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA. — Slower recovery from perturbations near a tipping point and its indirect signatures in fluctuation patterns have been suggested to alert catastrophes in a wide variety of systems. Recent studies of populations in the field and in the laboratory have used time-series data to confirm some of the theoretically predicted early warning indicators, such as an increase in recovery time or in the size and timescale of fluctuations. However, the performance of warning signals in spatially extended systems remains to be examined empirically. Here we use spatially extended yeast populations, an experimental system displaying a fold bifurcation, to evaluate early warning signals based on spatio-temporal fluctuations and to identify a novel warning indicator in space. We found that two leading indicators based on fluctuations increased before collapse of connected populations; however, the magnitude of increase was smaller than that observed in isolated populations, possibly because local variation is reduced by dispersal. Furthermore, we propose a generic indicator based on deterministic spatial patterns, "recovery length". As the spatial counterpart of recovery time, recovery length is defined as the distance for connected populations to recover from perturbations in space (e.g. a region of poor quality). In our experiments, recovery length increased substantially before population collapse, suggesting that the spatial scale of recovery can provide a superior warning signal before tipping points in spatially extended systems.

12:51PM B44.00007 Competitive Exclusion in Microbial Communities , CHARLES FISHER, PANKAJ MEHTA, Department of Physics, Boston University — The competitive exclusion principle of ecology suggests that two or more species cannot coexist in a community while living off of the same resources. Therefore, only species that occupy different niches can coexist. The process of community assembly is also heavily influenced by neutral drift due to stochastic birth, death and immigration of species. Currently, there is no consensus on the relative importance of "niche" and "neutral" processes in community assembly. We develop a stochastic birth-death-immigration model with competition for resources to examine the relative importance of these processes in microbial communities, and search for signatures of competitive exclusion in a large dataset of microbial community compositions containing relative species abundance data for thousands of environments. In addition, we discuss the role of metabolism in defining microbial niches.

1:03PM B44.00008 Quantifying genetic diversity under a broad spectrum of deleterious mutations , BENJAMIN GOOD, MICHAEL DESAI, Harvard University — Recent studies have shown that selection against deleterious mutations may play a major role in shaping observed patterns of sequence variation in natural populations. However, our understanding of these patterns remains limited, since selection creates correlations along the genome that are difficult to disentangle from each other. Previous theoretical work has focused on the qualitative effects of selection on sequence diversity, using simplified models in which all selected mutations have the same fitness cost. Yet is known that deleterious mutations follow a wide distribution in most organisms, so it is necessary to extend our theoretical predictions to this more general case before we can make quantitative connections with existing data. The evolutionary dynamics of this regime are complicated: extant mutant lineages represent large, correlated fluctuations away from the background expectation, which hinders efforts to apply existing methods based on deterministic or "mean-field" approximations. Here, we will describe recent progress towards this goal, which is based on a "coarse-graining" of the underlying distribution of fitnesses in the population.

1:15PM B44.00009 Cooperative Antibiotic Resistance in a Multi-Drug Environment , EUGENE YURTSEV, LEI DAI, JEFF GORE, Massachusetts Institute of Technology — The emergence of antibiotic resistance in bacteria is a significant health concern. A frequent mechanism of antibiotic resistance involves the production of an enzyme which inactivates the antibiotic. By inactivating the antibiotic, resistant cells can "share" their resistance with other cells in the bacterial population, suggesting that it may be possible to observe cooperation between strains that inactivate different antibiotics. Here, we experimentally track the population dynamics of two *E. coli* strains in the presence of two different antibiotics. We find that together the strains are able to grow in antibiotic concentrations that inhibit growth of either of the strains individually. We observe that even when there is stable coexistence between the two strains, the population size of each strain can undergo large oscillations. We expect that our results will provide insight into the evolution of antibiotic resistance and the evolutionary origin of phenotypic diversity and cooperative behaviors.

1:27PM B44.00010 Stochastic Loss of an Occasionally-Essential Function , ELIZABETH JERISON, MICHAEL DESAI, Harvard University — Many biological functions are useful only in specific circumstances. For example, hundreds of single-gene deletions in yeast increase growth rate in some laboratory conditions. During periods of disuse, these genes are vulnerable to disruption or loss via random mutation and genetic drift. Yet they are maintained in natural populations, suggesting that they must be useful at least occasionally. Here we quantify the risk of loss of such occasionally-important functions. We focus on predicting how the statistics of environmental change determine the mean time to loss of the function. Our results suggest a refinement to the Savageau 'use-it-or-lose-it' principle of regulation, and put theoretical lower bounds on how often these functions must be necessary to the organism, in order to be maintained.

1:39PM B44.00011 Rarely clicking Muller's ratchets , STEPHAN EULE, JAKOB METZGER, MPI for Dynamics and Self-Organization, Göttingen — In populations of finite size, weakly deleterious mutations can fix by chance. This phenomenon has been termed Muller's ratchet and one click of the ratchet refers to the loss of the fittest class of individuals with the fewest mutations. Despite the simplicity of the classical mathematical model of Muller's ratchet, surprisingly little is known in the biologically relevant regime where a click of the ratchet is a rare event. Here we show numerically that in this regime the rate of the ratchet strongly depends on the applied microscopic formulation (Wiright-Fisher/Moran) of the model, thus challenging the widely used diffusion approximation. Furthermore by employing a WKB-approximation in a simplified model, we obtain analytical results for the click rate, which agree well with the click rate of the full ratchet of the corresponding microscopical model.

1:51PM B44.00012 Evolution of Bacterial Suicide[1] , MARTIN TCHERNOOKOV, Physics Department, Emory University, ILYA NEMENMAN, Departments of Physics and Biology and Computational and Life Sciences Initiative, Emory University — While active, controlled cellular suicide (autolysis) in bacteria is commonly observed, it has been hard to argue that autolysis can be beneficial to an *individual* who commits it. We propose a theoretical model that predicts that bacterial autolysis is evolutionarily advantageous to an *individual* and would fixate in physically structured environments for stationary phase colonies. We perform spatially resolved agent-based simulations of the model, which predict that lower mixing in the environment results in fixation of a higher autolysis rate from a single mutated cell, regardless of the colony's genetic diversity. We argue that quorum sensing will fixate as well, even if initially rare, if it is coupled to controlling the autolysis rate. The model does not predict a strong additional competitive advantage for cells where autolysis is controlled by quorum sensing systems that distinguish self from nonself. These predictions are broadly supported by recent experimental results in *B. subtilis* and *S. pneumoniae*.

2:03PM B44.00013 Experimental Insights into Collective Effects in Eukaryotic Cell Proliferation in Dilute Suspensions , CARL FRANCK, IGOR SEGOTA, ARIANA STRANDBURG-PESHKIN, XIAO-QIAO S. ZHOU, ARCHANA RACHAKONDA, BENJAMIN YAVITT, CATHERINE J. LUSSENHOP, SUNGSU LEE, KEVIN THARRATT, AMRISH DESHMUKH, ELISABETH SEBESTA, MYRON ZHANG, SHARON LAU, SARAH BENNEDSEN, DAVID FRANCK, VIYATH FERNANDO, JUNSEOK OH, Cornell Univ. — Physicists can look to dilute suspensions of apparently solitary cells in suspension for elegant realizations of multicellular behavior. In contrast to our earlier work (Phys. Rev. E v. 77, 041905 (2008)) with the amoeba Dictyostelium discoideum we are discovering that the vital intercellular communications responsible for the well-known but poorly understood slow to fast transition in a growing culture as a function of time might be due to the passage of chemical messages between transient cell clusters or throughout the entire system as opposed to binary collisions. In considering the observed variation in proliferation rates we have been surprised to discover that for best growth cultures are much more dependent on incubator geometry than previously suspected.

Monday, March 18, 2013 11:15AM - 2:03PM –

Session B45 DBIO: Focus Session: Structure and Dynamics of Biomembranes II Hilton Baltimore Holiday Ballroom 4 - Mu-Ping Nieh, University of Connecticut

11:15AM B45.00001 Effect of Protein Crowding: Multivalent Protein Binding Induces a New Phase State in Lipid Membranes , TONYA KUHL, University of California, Davis — It is well known that lipid membrane properties change as a function of composition and phase state, and that protein-lipid interaction can induce changes in the membrane's properties and biochemical response. This talk demonstrates that multivalent binding of proteins to putative membrane receptors can induce structure changes and a new phase state in lipid membranes. These molecular level changes are precisely characterized using grazing incidence X-ray diffraction. Protein binding is shown to perturb lipid packing within lipid monolayers and bilayers resulting in topological defects and the emergence of a new orientationally textured lipid phase. In bilayers this altered lipid order is transmitted from the receptor laden exterior membrane leaflet to the inner leaflet, representing a potential mechanism for lipid mediated outside-in signaling by multivalent protein binding.

11:51AM B45.00002 Stabilization of composition fluctuations in mixed membranes by hybrid lipids , SAMUEL SAFRAN, BENOIT PALMIERI, Weizmann Institute of Science — A ternary mixture model is proposed to describe composition fluctuations in mixed membranes composed of saturated, unsaturated and hybrid lipids. The asymmetric hybrid lipid has one saturated and one unsaturated hydrocarbon chain and it can reduce the packing incompatibility between saturated and unsaturated lipids. A methodology to recast the free-energy of the lattice in terms of a continuous isotropic field theory is proposed and used to analyze composition fluctuations above the critical temperature. The effect of hybrid lipids on fluctuations domains rich in saturated/unsaturated lipids is predicted. The correlation length of such fluctuations decreases significantly with increasing amounts of hybrids even if the temperature is maintained close to the critical temperature. This provides an upper bound for the domain sizes expected in rafts stabilized by hybrids, above the critical temperature. When the hybrid composition of the membrane is increased further, a crossover value is found above which "stripe-like" fluctuations are observed. The wavelength of these fluctuations decreases with increasing hybrid fraction and tends toward a molecular size in a membrane that contains only hybrids.

12:03PM B45.00003 Self-assembly of colloidal rafts , PRERNA SHARMA, Brandeis University, THOAMS GIBAUD, Ecole Normale Supérieure de Lyon, ANDREW WARD, ZVONIMIR DOGIC, Brandeis University — Interactions between nanometer-sized particles or molecules suspended in a bulk fluid are well understood. However, when such particles are embedded in a membrane, the inter-particle potential is significantly modified by membrane mediated forces and gives rise to novel phase behavior. Visualizing and manipulating such inclusions in a lipid bilayer is difficult due to the nanometer length scales involved. Here, we use a model system of micron sized colloidal membranes doped with molecules shorter or longer than that of the bulk. Surprisingly, the dopant molecules form self-limited finite size clusters. These clusters further self-organize into a wide variety of higher order structures such as hexagonal and square lattice arrays, lamellar patterns and saddle shaped surfaces. Understanding the phase behavior and measuring repulsive forces between such clusters may have implications for the similar mechanisms that operate in conventional lipid bilayers.

12:15PM B45.00004 Mechanism of lipid bilayer penetration by mixed monolayer-protected gold nanoparticles , REID VAN LEHN, PRABHANI ATUKORALE, MIT, RANDY CARNEY, FRANCESCO STELLACCI, EPFL, DARRELL IRVINE, ALFREDO ALEXANDER-KATZ, MIT — Recently, gold nanoparticles (AuNPs) protected by a binary mixture of hydrophobic and hydrophilic alkanethiol ligands were observed to spontaneously penetrate cellular membranes via a non-specific mechanism. Penetration was observed even at low temperatures and in the presence of endocytotic inhibitors, implying that AuNPs crossed the membrane by a non-endocytotic process. Furthermore, penetration was shown to depend on the amphiphilicity and nanoscale morphology of the protecting monolayer. In this work, we use a variety of simulation techniques to elucidate the mechanism of lipid bilayer penetration and compare our results to experiments with lipid vesicles. We show that these AuNPs can stably embed within lipid bilayers by "snorkeling" charges out of the bilayer core; the stability of such a state is a function of particle size, the composition of the protecting monolayer, and other environmental conditions. We use detailed simulations to analyze structural changes in the surrounding lipids and show that the energy barrier for embedding is considerably reduced in the presence of bilayer defects. We expect that these results will enable the design of novel drug delivery carriers and biosensors.

12:27PM B45.00005 ABSTRACT WITHDRAWN –

12:39PM B45.00006 Dynamics and Self-Assembly of Nanoparticles on Biomembranes[1] , RUPAK BHATTACHARYA, VISHAL MAINGI, SUBBARAO KANCHI, Department of Physics, IISc Bangalore, BAGUL RAHUL SURESH, Department of Organic Chemistry, IISc Bangalore, N JAYARAMAN, Department of Organic Chemistry, IISc Bangalore, PRABAL MAITY, Department of Physics, IISc Bangalore, K.G AYAPPA, Department of Chemical Engineering, IISc Bangalore, JAYDEEP BASU, Department of Physics, IISc Bangalore — We have recently been investigating the diffusion mediated self-assembly of various types of Dendrimers on supported DMPC lipid bilayer. Atomic Force Microscopy is used to study the pattern formation for PETIM dendrimers of different core composition as well as of generations. Extensive studies have been carried out using different concentration and different packing of lipid molecules constituting the lipid bilayer. Interestingly Oxygen Core dendrimer forms regular circular patterns on membranes whereas the Nitrogen Core dendrimer do not. A fully atomistic Molecular Dynamics simulation with implicit water clearly shows the evidence of domain formation for O-core dendrimers on bilayer, which is absent in the other one. Different generation for Oxygen core dendrimers forms patterns with a pore inside. The reduction of the diameter of these patterns with decreasing packing of lipid molecules indicates the possible role of lipid molecules in aggregation process. Further study using Confocal Fluorescence Correlation Spectroscopy is underway to correlate this type of membrane mediated pattern formation with underlying lipid diffusion.

12:51PM B45.00007 Cholesterol Translocation in a Phospholipid Membrane , AMIT CHOUBEY, RAJIV KALIA, Collaboratory for Advanced Computing and Simulations, USC, NOAH MALMSTADT, Mork Family Department of Chemical Engineering and Materials Science, USC, AIICHIRO NAKANO, PRIYA VASHISTHA, Collaboratory for Advanced Computing and Simulations, USC — Cholesterol (CHOL) molecules play a key role in modulating the rigidity of cell membranes, and controlling intracellular transport and signal transduction. Using all-atom molecular dynamics and the parallel replica approach, we study the process of CHOL interleaflet transport (flip-flop) in a dipalmitoylphosphatidycholine (DPPC)–CHOL bilayer, the effect of this process on mechanical stress across the bilayer, and the role of CHOL in inducing molecular order in the respective bilayer leaflets. The simulations are carried out at physiologically relevant CHOL concentration (30%), temperature 323 K and pressure 1 bar. CHOL flip-flop events are observed with a rate constant of 3×10^4 s^{-1}. Once a flip-flop event is triggered, a CHOL molecule takes an average of 73 nanoseconds to migrate from one bilayer leaflet to the other.

1:03PM B45.00008 Simulating liquid-liquid phase separation and lipid transport on the Anton special purpose machine , EDWARD LYMAN, Department of Physics and Astronomy and Department of Chemistry and Biochemistry, University of Delaware, LOGAN SANDAR, Department of Physics and Astronomy, University of Delaware, ALEXADER SODT, RICHARD W. PASTOR, Laboratory of Computational Biology, National Heart, Lung, and Blood Institute — We present simulation data for a bilayer composed of a ternary mixture of cholesterol, dioloeoyl phosphatidylcholine and dipalmitoyl phosphatidylcholine. The composition is chosen to be in the two-phase region and the temperature in the vicinity of the miscibility transition. Using the Anton special purpose computer to generate continuous trajectories longer the ten microseconds—which admits complete mixing of the lipids—we observe robust liquid-liquid phase coexistence. The time-and ensemble-averaged mean squared displacement (MSD) displays anomalous scaling on timescales less than 50 nsec and normal diffusion on longer timescales. The short-time anomalous scaling is explained by a mode-coupling argument[Flenner et al Phys Rev E 79:011907(2009)]. The per-lipid MSD's suggest that a few lipids remain associated with the liquid ordered domain for the duration of the simulation, suggesting a possible mechanism for anomalous transport on experimentally accessible timescales.

1:15PM B45.00009 Interaction of Ionic Liquids with Lipid Biomembrane: Implication from Supramolecular Assembly to Cytotoxicity , BENXIN JING, NAN LAN, Y. ELAINE ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame, Notre Dame, Indiana 46556, United States — An explosion in the research activities using ionic liquids (ILs) as new "green" chemicals in several chemical and biomedical processes has resulted in the urgent need to understand their impact in term of their transport and toxicity towards aquatic organisms. Though a few experimental toxicology studies have reported that some ionic liquids are toxic with increased hydrophobicity of ILs while others are not, our understanding of the molecular level mechanism of IL toxicity remains poorly understood. In this talk, we will discuss our recent study of the interaction of ionic liquids with model cell membranes. We have found that the ILs could induce morphological change of lipid bilayers when a critical concentration is exceeded, leading to the swelling and tube-like formation of lipid bilayers. The critical concentration shows a strong dependence on the length of hydrocarbon tails and hydrophobic counterions. By SAXS, Langmuir-Blodgett (LB) and fluorescence microscopic measurement, we have confirmed that tube-like lipid complexes result from the insertion of ILs with long hydrocarbon chains to minimize the hydrophobic interaction with aqueous media. This finding could give insight to the modification and adoption of ILs for the engineering of micro-organisms.

1:27PM B45.00010 The Effect of Tension on Phase Transitions and Domains in Phospholipid Membranes , MARIA SANTORE, University of Massachusetts Polymer Science, DONG CHEN, University of Massachusetts Physics — The relevance phase transitions in phospholipid membranes to the effect of confinement on phase transitions and to the structure-function relationship in biological membranes has driven decades of scientific study of the behavior of model membranes. A primary focus of these studies has been the impact of temperature. We argue here, however, that tension can have a profound impact on transitions, suppressing domain formation, or shifting the nature of the domains themselves. While Clausius-Clapeyron predicts depression of a melting transition as small as 1/3 C for every mN/m of applied tension, the presence of a triple point or similar features can lead to the formation of different domains altogether. We provide here dramatic demonstrations of these behaviors in the form of fluorescence microscopy images in systems with controlled tension.

1:39PM B45.00011 Confinement of 5CB Between Lyotropic Bilayers , CORY DOLBASHIAN, RIZWAN MAHMOOD, Slippery Rock University, TOMMASO BELLINI, University of Milano, Italy, NOEL CLARK, University of Colorado, Boulder — We report phase behavior of mixtures of 5CB (4-Cyano-4'-Pentyl-1, 1'-biphenyl), a calamitic thermotropic liquid crystal, with mixtures of the lyotropic double tailed cationic surfactant DDAB (diodecyldimethylammonium-bromide) and water. These mixtures had a fixed ratio of DDAB to water (75% / 25%) and 5CB concentrations ranging from 10% to 85%. Our preliminary phase diagram suggests transition from isotropic to lamellar phase having higher birefringence at higher DDAB concentration. We have also observed low vale of birefringence at lower DDAB concentration suggesting swelling of bilayers.

1:51PM B45.00012 Bilayer thickness mismatch controls domain size in biomimetic membranes , FREDERICK A. HEBERLE, Oak Ridge National Laboratory, ROBIN S. PETRUZIELO, Cornell, JIANJUN PAN, PAUL DRAZBA, University of Tennessee, NORBERT KUČERKA, NRC, Canada, Comenius Univ., Slovakia, ROBERT F. STANDAERT, ORNL, Univ. of Tenn, GERALD W. FEIGENSON, Cornell, JOHN KATSARA, ORNL, Univ. of Tenn., NRC, Canada — In order to promote functionality, cells may alter the spatial organization of membrane lipids and proteins, including separation of liquid phases into distinct domains. In model membranes, domain size and morphology depend strongly on composition and temperature, but the physicochemical mechanisms controlling them are poorly understood. Theoretical work suggests a role for interfacial energy at domain boundaries, which may be driven in part by thickness mismatch between a domain and its surrounding bilayer. However, no direct evidence linking thickness mismatch to domain size in free-standing bilayers has been reported. We describe the use of Small Angle Neutron Scattering (SANS) to detect domains in simplified lipid-only models that mimic the composition of plasma membrane. We find that domain size is controlled by the degree of acyl chain unsaturation of low-melting temperature lipids, and that this size transition is correlated to changes in the thickness mismatch between coexisting liquid phases.

Session B46 SPS: SPS Undergraduate II Hilton Baltimore Holiday Ballroom 5 - Crystal Bailey, American Physical Society

11:15AM B46.00001 Redesign of an AC Magnetic Susceptometer for Measurements in Smaller Samples[1] , ANDRES VARGAS, RYAN FUKUDA, SMITHA SUNNY, PEI-CHUN HO, Department of Physics, California State University, Fresno — A new AC magnetic susceptometer was created for the purpose of measuring the magnetic properties of smaller samples, such as nanoparticles that are currently being synthesized in our lab. The susceptometer consists of a primary coil, a secondary coil, and a sample holder. The primary coil is the outer component of the susceptometer, which provides a magnetic field when current is applied due to Ampere's Law. Inside of the primary coil lies the secondary coil, which has two oppositely wound solenoids; they are oppositely wound to reduce background signal. The sample holder lies inside of the secondary coil with the sample. All of these go inside of a beryllium copper casing for protection. We tested the susceptometer by looking for the ferromagnetic phase transition of an 11 mg Gd sample. A $\sim 100\mu$A AC current was applied to the primary coil, which created a magnetic field that polarized the magnetic moments in the sample. This induced a voltage on the secondary coil, which is proportional to the magnetic susceptibility. We measured the temperature dependency of the induced voltage from 10 K to 300 K. The results showed a sharp increase in the induced voltage around 293K, which agrees with the known ferromagnetic transition of Gd.

11:27AM B46.00002 Electrospun fibers of PLA/P3HT blends for device and sensor applications[1] , WILLIAM SERRANO, NICHOLAS PINTO, University of Puerto Rico - Humacao — The thermoplastic aliphatic polyester, poly (lactic acid) (PLA) is a biodegradable polymer that is sometimes used in implant screws for bone repair. Our focus was to fabricate fibers of this polymer and its blends with p-doped poly (3-hexylthiophene)-(P3HT) in order to extend its use to devices and/or sensors. PLA/P3HT fibers were prepared in air at room temperature using the electrospinning technique that is cheap, fast and reliable. Scanning Electron Microscope images of the fibers reveal that the presence of P3HT does not affect the fabrication of PLA fibers at low or high polymer concentrations in chloroform, retaining the same morphological structure of pure PLA fibers. The fiber diameters were in the range 1-10 microns. A slight increase in fiber formation results with the addition of P3HT, most likely due to a reduction of the solution surface tension. Results of the electrical characterization of this material will be presented.

11:39AM B46.00003 AC Circuit Measurements with a Differential Hall Element Magnetometer[1]

MATTHEW W. CALKINS, B. SCOTT NICKS, PEDRO A. QUINTERO, MARK W. MEISEL, Department of Physics, University of Florida — As the biomedical field grows, there is an increasing need to quickly and efficiently characterize more samples at room temperature. An automated magnetometer was commissioned to do these room temperature magnetic characterizations. This magnetometer, which is inspired by a Differential Hall Element Magnetometer,[2] uses two commercially available Hall elements wired in series. One Hall element measures the external magnetic field of a 9 T superconducting magnet and the other measures the same external field plus the field due to the magnetization of the sample that sits on top of the Hall element. The difference between these two Hall elements is taken while a linear stepper motor sweeps through the external magnetic field. The linear motor and data acquisition are controlled by a LabVIEW program. Recently, the system was outfitted for AC circuit measurements and these data will be compared to DC circuit data. In addition, the lowest signal to noise ratio will be found in order to deduce the smallest amount of sample needed to register an accurate coercive field.

11:51AM B46.00004 Low Temperature Probe for Measuring Anisotropic Magnetotransport[1]

, GALIN DRAGIEV, DANIEL GRANT, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Certain materials display a change in resistance when a magnetic field is applied on them. This resistance change is called magnetoresistance (MR). The value of MR may also depend on the direction of the magnetic field relative to the crystal structure of the material, which is called anisotropic MR (AMR). We built a probe which allows us to measure the AMR of a sample in a temperature range of 1.2 K to 300K in magnetic fields of up to 9 tesla. The probe design allows the angle between the magnetic field and a particular direction of the sample to be changed over almost the entire solid angle of 4π. In particular, this probe lets us measure the AMR of a sample with magnetic anisotropy when the magnetic field is applied either along the hard or easy axes, or somewhere in between. The probe allows us to change the orientation of the sample while it is inside the low temperature cryostat. We will present our data on hole-doped manganese oxide (manganite) thin films and discuss the possible origins of AMR in these materials.

12:03PM B46.00005 Probing Quantum Turbulence in He II with a MEMS Oscillator[1]

, ALEKSANDER LEVENTAL, JOSH BAUER, MIGUEL GONZALEZ, PAN ZHENG, YOONSEOK LEE, University of Florida, HO BUN CHAN, The Hong Kong University of Science and Technology — Micrometer scale mechanical oscillators based on MEMS technology have been developed for the study of quantum fluids and have been tested successfully at ultra low temperatures. Our recent low temperature test [1] in which the device was immersed in the superfluid phase of ^{4}He revealed striking behavior below 400 mK: nonlinear and hysteretic resonance at high excitations. The observed phenomenon is thought to be related to vortices and quantum turbulence and warrants a systematic investigation for better understanding. We constructed an experimental set-up that allows us to cool a MEMS device in liquid ^{4}He down to 50 mK at pressures up to 25 bar. We will discuss our new set-up and present our preliminary results performed at saturated vapor pressure.

12:15PM B46.00006 Exploration of Quartz Tuning Forks as Potential Magnetometers for Nanomagnets[1]

, B. SCOTT NICKS, MATTHEW W. CALKINS, PEDRO A. QUINTERO, MARK W. MEISEL, Department of Physics, University of Florida — A change in the resonance frequency, $f_0 \approx 32$ kHz, of quartz tuning forks is expected when nano-sized magnetic particles or films are applied to a fork that is then exposed to a variable magnetic field. This work explores the feasibility of using these forks, once removed from their protective canisters, as potentially inexpensive magnetometers operating at room temperature in fields up to 2 T, and eventually up to 9 T, by analyzing the responses of loaded forks in such a field. However, the forks are also dependent on subtle variations of the ambient temperature, and the magnetic leads may present a background signal that must be subtracted. Preliminary results are encouraging, but better understanding of the noise sources must be made for these forks to be used as envisioned.

[1]Supported, in part, by the NSF via DMR-1156737 (UF Physics REU Program) and DMR-1202033 (MWM). We acknowledge early contributions to this work by Philip D. Javernick (UF Physics REU 2011).

12:27PM B46.00007 Toward CN-VFET logic circuits[1]

, STEPHEN GILBERT, BO LIU, MITCHELL MCCARTHY, EVAN DONOGHUE, ANDREW RINZLER, University of Florida, Department of Physics — Gate field modulation of the Fermi level in the low density of electronic states carbon nanotubes provides a new control mechanism for modulating the Schottky barrier between the nanotubes and a semiconductor to control charge injection across their interface. This has been exploited in the recently developed carbon nanotube-enabled vertical field effect transistor (CN-VFET) comprised of a bottom gate, dielectric layer, dilute nanotube source electrode, semiconducting channel layer, and drain electrode situated in a collinear, vertical stack. Since the channel length in this architecture is simply the thickness of a thin film, the naturally short channel lengths can overcome the relatively low mobility of organic semiconductors to source higher on-state currents or potentially improve operating speeds. Prototype logic gates using such organic transistors have yet to be demonstrated. As a step in this direction we have fabricated organic CMOS inverters utilizing a p-type and an n-type CN-VFET. The device fabrication, materials used, performance and progress toward a CN-VFET ring oscillator will be discussed.

12:39PM B46.00008 Pressure Dependence of MEMS Oscillator Quality Factor[1]

, JOSHUA BAUER, University of Florida, SARAH GEIGER[2], Millersville University, MIGUEL GONZALEZ, PAN ZHENG, YOONSEOK LEE, University of Florida — This paper details a study in which the pressure dependence of the quality factor and resonance frequency of a micro-electro-mechanical device is examined. The results obtained will aid in the understanding of the effects of slide film damping in various gasses on oscillators operating at micrometer length scales. The device utilized was a capacitively driven plate oscillator positioned 1.25μm above a silicon substrate. The dominant damping mechanism for this geometry is slide film damping from the gaseous film between the oscillating plate and substrate. The mechanical resonance of the device was characterized as a function of pressure from 6 mTorr to 1 atm in air. We observed three distinct damping regimes in the quality factor. In addition to the characterization performed in air, pressure dependences in helium and argon were also examined at pressure ranges of 6.5 mTorr to 5 Torr and 750mTorr to 760 Torr, respectively.

12:51PM B46.00009 Intrinsic Localized Modes in nonlinear two-dimensional electrical lattices , J.F. STORMES, L.Q. ENGLISH, Dickinson College, F. PALMERO, University of Seville, Spain, P.G. KEVREKIDIS, University of Massachusetts, DICKINSON COLLEGE COLLABORATION, UNIVERSITY OF SEVILLE COLLABORATION, UNIVERSITY OF MASSACHUSETTS COLLABORATION — We report on the generation of stationary and traveling intrinsic localized modes (ILMs), also called discrete breathers or discrete solitons, in two dimensions in damped-driven electrical lattices. ILMs are spatially localized eigenmodes that arise due to the nonlinearity of the system, not due to spatial impurities. Since solitons are generally unstable in two dimensions, the existence of these ILMs relies on the discreteness of the lattice. We show experimentally that depending on the frequency and amplitude of the spatially uniform driving, different numbers of ILMs can be induced in both square and hexagonal lattices. In lattices that allow ILM motion, we furthermore study the interaction of such modes.

1:03PM B46.00010 Thermal effects of laser illumination on coated quartz crystal microbalance surfaces[1] , BENJAMIN KELLER, KEELEY STEVENS, LIMING PAN, JACQUELINE KRIM, North Carolina State University — Prior work on the thermal sensitivity of quartz crystal microbalances (QCM) has shown them to be powerful tools, capable of measuring milli-Kelvin temperature impulses while also presenting a well-understood response to steady state heating [1]. This has been demonstrated for physical contact to the QCM surface via a STM tip with a temperature differential [2]; here we present a novel application wherein a laser is focused onto the coated QCM, thus applying a non-contact thermal pulse. By applying variable length (second to minute) exposures from a laser source we can isolate the thermal shock, time decay and gross heating effects. The system is sensitive to the coating used, showing significant differences in heating for absorbative and reflective coatings. This method is unique in that the QCM measures energy lost into the substrate, unlike standard techniques which focus primarily on material efficiency. This has potential to characterize various coatings used in solar cells and thermal collectors, as well as in photovoltaic materials.

1:15PM B46.00011 Spectrum, symmetries, and dynamics of Heisenberg spin-1/2 chains , KIRA JOEL, DAVIDA KOLLMAR, LEA SANTOS, Yeshiva University — Quantum spin chains are prototype quantum many-body systems. They are employed in the description of various complex physical phenomena. Here we provide an introduction to the subject by focusing on the time evolution of Heisenberg spin-1/2 chains with couplings between nearest-neighbor sites only. We study how the anisotropy parameter and the symmetries of the model affect its time evolution. Our predictions are based on the analysis of the eigenvalues and eigenstates of the system and then confirmed with actual numerical results.

1:27PM B46.00012 High temperature series expansion and the exact solution study of the 1/5 depleted square lattice Ising model[1] , SIMEON HANKS, TRINANJAN DATTA, Augusta State University , JAAN OITMAA, The University of New South Wales — The critical behavior of the 1/5 depleted square-lattice Ising model with nearest neighbor ferromagnetic interaction has been investigated by means of both a high-temperature series expansion and an exact solution. The critical point in the coupling constant has been accurately determined with a series expansion up to order eighteen in the high temperature expansion parameter. For the exact solution we use a set of decoration transformations to recast the original model in terms of a set of nearest neighbor, next-nearest neighbor, and four spin interaction Ising model. This is followed by a transformation to a staggered 8-vertex model. As the vertex weights satisfy the free-fermion condition the free energy and critical point are obtainable by standard methods.

1:39PM B46.00013 Developing an Embedded Atom Method Potential for Copper , BEN STORTENBECKER, BRIAN DEMASKE, VASILY ZHAKHOVSKY , IVAN OLEYNIK, University of South Florida — A new embedded-atom method (EAM) interatomic potential for copper has been developed in order to improve upon the predictive power of atomistic simulations under extremes of pressures and temperatures induced by shock compression and ultrashort laser irradiation. Several candidate potentials were fit to a database consisting of *ab initio* cold pressure tensor components calculated for a wide range of hydrostatic and uniaxial deformations as well as experimental properties near equilibrium conditions. The close relationship between the stress tensor and interatomic forces under naturally-occurring material states ensures the accuracy of the potential without the need for a large number of fitting points. After fitting, the candidates were then screened against the experimental melting point in order to select a single best potential. This final potential will be verified against the experimental melting line, liquid-vapor coexistence curve, and the shock Hugoniot.

1:51PM B46.00014 Surface-induced reduction of the spin coherence times of nitrogen-vacancy centers in diamond , JEFFREY M. MOORE, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa — The exceptionally long room-temperature spin coherence times of nitrogen-vacancy (NV) centers in diamond indicate their potential utility for quantum information processing. The remarkable sensitivity of the spin dynamics of NV centers to electric and magnetic fields, and to strain, also suggests these centers can be used in novel sensors. The sensitivity and spatial resolution of such a sensor will depend on the depth of the NV center below the diamond surface. Local relaxation of the atomic positions near the diamond surface, however, will strain the NV center and consequently reduce its spin coherence time. We evaluate this effect by calculating the strain near a (001) diamond surface using density functional theory. The strain for a specific NV-center depth was evaluated using the linearized augmented plane wave (LAPW) method and the Perdew-Burke-Ernzerhof (PBE) exchange correlation functional within the WIEN2k density functional code. The effect of the resulting strain values on the spin coherence times were determined using a low-energy effective Hamiltonian for the NV-center energies and wave functions, and their strain dependence. This work was supported by an AFOSR MURI.

2:03PM B46.00015 Density of States of Type-II Superconductors in High Magnetic Field and Low Temperatures[1] , RENZO VILLAZON, OWEN LEHMER, JULIAN IRWIN, SASHA DUKAN, Goucher College, Baltimore, MD 21204 — In high magnetic fields and at low temperatures, electronic energies are quantized in the form of Landau levels. The inclusion of Landau level quantization in the superconducting pairing (both diagonal and off-diagonal) leads to gapless points on the Fermi surface. Within this theory, the density of states of a type-II superconductor in the range of magnetic fields $0.2B_{c2} < B < B_{c2}$ is calculated. The influence of disorder on the density of states is investigated for a range of impurity concentrations and scattering potential strengths. We compare our theoretical predictions to experimental results for superconductor YNi_2B_2C and find that our model is reliable at high magnetic fields but has limited applicability at lower fields.

Session B47 DBIO DMP: Invited Session: Physical Organizing Principles of Biomineral Formation Hilton Baltimore Holiday Ballroom 6 - Susan N. Coppersmith, University of Wisconsin

11:15AM B47.00001 Phase transitions and their energetics in calcite biominerals , PUPA GILBERT, University of Wisconsin - Madison — Biominerals include mollusk shells and the skeletons of algae, sponges, corals, sea urchins and most other animals. The function of biominerals are diverse: mechanical support, attack, defense, grinding, biting, and chewing, gravitational and magnetic field sensing, light focusing, and many others. The exquisite nanostructure of biominerals is directly controlled by the organisms, which have evolved to master the chemico-physical aspects of mineralization. By controlling the inorganic precursor nanoparticle size, packing, and phase transitions, organisms efficiently fill space, produce tough and hard structures, with micro- or macroscopic morphology optimized for their functions. Specifically, this talk will address two key questions: Q: How are the beautiful biomineral morphologies achieved? A: Using amorphous precursor phases, with phase transitions kinetically regulated (retarded) by proteins. Q: How do organisms co-orient their single-crystalline biominerals? A: Controlling the propagation of crystallinity one nanoparticle at a time, not atom-by-atom.

11:51AM B47.00002 Bottom-up molecular models of hierarchical mineralized tissues: Structure, mechanics, biology , MARKUS J. BUEHLER, Massachusetts Institute of Technology — Biological materials are intriguing examples of advanced materials, which are synthesized, controlled and used for an astonishing variety of purposesstructural support, force generation, mass transport, catalysis, or energy conversion. By incorporating concepts from biology and engineering, computational modeling has led the way in identifying the core principles that link the molecular structure of biomaterials at scales of nanometers to macroscopic scales through hierarchical structures. Here we review case studies of a range of mineralized tissues, focused on bottom-up models and analyses of the structure and mechanics of mineralized tissues. We report an atomistic model of collagen, bone and describe the process of mineralization and the interplay of different hierarchical levels. Combined with experimental studies, such *in silico* models allow us to simulate disease, understand catastrophic failure of tissues, and enable us to translate concepts from the living world into material designs that blur the distinction between the living and non-living systems.

12:27PM B47.00003 Reverse engineering biological crystal growth , DERK JOESTER, Northwestern University — No abstract available.

1:03PM B47.00004 Bio-Inspired Approaches to Crystals with Composite Structures[1] , FIONA MELDRUM, University of Leeds — Advances in technology demand an ever-increasing degree of control over material structure, properties and function. As the properties of monolithic materials are necessary limited, one route to extending them is to create a composite by combining contrasting materials. The potential of this approach is beautifully illustrated by the formation of biominerals where organic macromolecules are combined with brittle minerals such as calcite to create crystals with considerable fracture toughness. This talk will discuss how bio-inspired approaches can be used to generate single crystals with composite crystals through a simple one-pot method. By precipitating calcite crystals in the presence of "occlusion species" ranging from latex particles, to organic and inorganic nanoparticles and finally small molecules we demonstrate that high amounts of foreign species can be incorporated through control over the additive surface chemistry, and that this can lead to an enhancement of the mechanical properties of the calcite. Occlusion of 20 nm anionic diblock copolymer micelles was achieved at levels of over 13 wt%, and the properties of the resuktant composite calcite crystals were measured using a range of techniques including IR spectroscopy, high resolution powder XRD and high resolution TEM. Incorporation of these macromolecules leads to crystals with structures and mechanical properties similar to those of biominerals. With sizes in the range of some intracrystalline proteins, the micelles act as "pseudo-proteins", thereby providing an excellent model system for investigation of the mechanism of macromolecule insertion within biominerals. Extension of these studies to the incorporation of small molecules (amino acids) again demonstrated high levels of incorporation without any change in the crystal morphology. Further, occlusion of these small molecules within the calcite lattice again resulted in a significant increase in the hardness of the calcite, a result which appears to derive from an increase in lattice strain on molecular occlusion. Finally, the generality of this strategy is demonstrated by its extension to the incorporation of inorganic particles such as magnetite and gold within calcite, leading to the formation of inorganic-inorganic composites.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C1 DCMP: Invited Session: Spin-Orbit-Controlled Ground States in Single-Crystal Iridates Ballroom I - Lance De Long, University of Kentucky

2:30PM C1.00001 Pressure and Doping Effects in Layered Iridates , GANG CAO, University of Kentucky — No abstract available.

3:06PM C1.00002 Tuning the Spin-Orbit Coupled Ground State of Iridates with Pressure , DANIEL HASKEL, Argonne National Laboratory — The electronic ground state of the novel magnetic insulators $BaIrO_3$ [1] and Sr_2IrO_4 [2] is probed at ambient and high-pressure conditions using x-ray absorption and magnetic circular dichroism measurements. A spin-only description of the magnetic ground state is ruled out, spin-orbit entanglement in 5*d*states resulting in comparable orbital (L_z) and spin (S_z) contributions to the localized magnetic moments despite the presence of strong crystal fields and band effects in Ir *5d* states. Pressures of $\sim$ 5 GPa and 20 GPa quench the "weak" ferromagnetic ordering in $BaIrO_3$ and Sr_2IrO_4, respectively, despite robust local moments and insulating behavior remaining at these pressures, confirming the Mott character of the insulating gap. The expectation value of the angular part of the S-O interaction, $<\mathbf{L}\bullet\mathbf{S}>$, extrapolates to zero at 80–90 GPa in Sr_2IrO_4 where an increased bandwidth strongly mixes J_{eff} =1/2, 3/2 states and S-O interactions no longer dominate the electronic ground state. The likely appearance of a single, metallic band at a pressure of $\sim$ 1 Mbar (100 GPa) provides an exciting backdrop for searches of superconductivity at high pressures [3]. Work at Argonne is supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC-02-06CH11357.

3:42PM C1.00003 Twisted Hubbard Model for Sr_2IrO_4: Magnetism and Possible High Temperature Superconductivity , T. SENTHIL, Massachusetts Institute of Technology — Sr_2IrO_4 has been suggested as a Mott insulator from a single $J_{eff} = 1/2$ band, similar to the cuprates. However this picture is complicated by the measured large magnetic anisotropy and ferromagnetism. Based on a careful mapping to the $J_{eff} = 1/2$ (pseudospin-1/2) space, we propose that the low energy electronic structure of Sr_2IrO_4 can indeed be described by a SU(2) invariant pseudospin-1/2 Hubbard model very similar to that of the cuprates, but with a "twisted" coupling to external magnetic field (a g-tensor with a staggered antisymmetric component). This perspective naturally explains the magnetic properties of Sr_2IrO_4. We also derive several simple facts based on this mapping and the known results about the Hubbard model and the cuprates, which may be tested in future experiments on Sr_2IrO_4. In particular we propose that (electron-)doping Sr_2IrO_4 can potentially realize high-temperature superconductivity.

4:18PM C1.00004 Exotic Physics from Doping a Strongly Spin-Orbit Coupled Mott Insulator

, YUE CAO, University of Colorado at Boulder — Doping a Mott insulator, as in the case of high T_c cuprates, has given rise to many exotic physics in the doping diagram, such as the pseudogap, Fermi arc and vortex phase. An important topic in these strongly correlated systems is to distinguish the properties that are intrinsic to the Mott physics from those that are materials specific. Recent studies of Sr_2IrO_4, whose Mottness requires strong spin orbit coupling, provide a new venue to look into the topic, where the spin, orbital, charge and lattice degrees of freedom interact. Using ARPES we studied the evolution of the electronic structure of Sr_2IrO_4 with both Rh and La doping. We show that the Rh substitution acts as immobile effective local holes, without a strong renormalization of the overall band structure, while La acts as an electron dopant. Particularly interesting is the lightly hole-doped regime, which showcases some of the same exotic physics as seen in the cuprates, including pseudogaps and Fermi arcs. By observing the scattering rate evolution as a function of energy and temperature, we confirm the non-Fermi liquid nature of the Fermi arc.

4:54PM C1.00005 Magnetic and crystal structures of the honeycomb lattice Na_2IrO_3 and single layer Sr_2IrO_4[1]

, FENG YE, Oak Ridge National Laboratory — $5d$ based iridates have recently attracted great attention due to the large spin-orbit coupling (SOC). It is now recognized that the SOC that competes with other relevant energies, particularly the on-site Coulomb interaction U, and have driven novel electronic and magnetic phases [1-3]. Combining single crystal neutron and x-ray diffractions, we have investigated the magnetic and crystal structures of the honeycomb lattice Na_2IrO_3 [4]. The system orders magnetically below 18.1 K with Ir^{4+} ions forming zigzag spin chains within the layered honeycomb network with ordered moment of 0.22 μB /Ir site. Such a configuration sharply contrasts the Neel or stripe states proposed in the Kitaev-Heisenberg model. The structure refinement reveals that the Ir atoms form nearly ideal 2D honeycomb lattice while the IrO_6 octahedra experience a trigonal distortion that is critical to the ground state. The results of this study provide much-needed experimental insights into the magnetic and crystal structure crucial to the understanding of the exotic magnetic order and possible topological characteristics in the $5d$-electron based honeycomb lattice. Neutron diffraction experiments are also performed to investigate the magnetic and crystal structure of the single layer iridate Sr_2IrO_4, where new structural information and spin order are obtained that is not available from previous neutron powder diffraction measurement.

Session C2 DCMP: Invited Session: Coulomb Drag and Exciton Condensation in Semiconductor and Graphene Double Layers

Ballroom II - Michael Lilly, Sandia National Laboratories

2:30PM C2.00001 Exciton Transport and Perfect Coulomb Drag[1]

, DEBALEENA NANDI, California Institute of Technology — Exciton condensation is realized in closely-spaced bilayer quantum Hall systems at $\nu_T = 1$ when the total density in the two 2D electron layers matches the Landau level degeneracy. In this state, electrons in one layer become tightly bound to holes in the other layer, forming a condensate similar to the Cooper pairs in a superconductor. Being charge neutral, these excitons ought to be free to move throughout the bulk of the quantum Hall fluid. One therefore expects that electron current driven in one layer would spontaneously generate a "hole" current in the other layer, even in the otherwise insulating bulk of the 2D system. We demonstrate precisely this effect, using a Corbino geometry to defeat edge state transport. Our sample contains two essentially identical two-dimensional electron systems (2DES) in GaAs quantum wells separated by a thin AlGaAs barrier. It is patterned into an annulus with arms protruding from each rim that provide contact to each 2DES separately. A current drag geometry is realized by applying a drive voltage between the outer and inner rim on one 2DES layer while the two rims on the opposite layer are connected together in a closed loop. There is no direct electrical connection between the two layers. At $\nu_T = 1$ the bulk of the Corbino annulus becomes insulating owing to the quantum Hall gap and net charge transport across the bulk is suppressed. Nevertheless, we find that in the drag geometry appreciable currents do flow in each layer. These currents are almost exactly equal magnitude but, crucially, flow in opposite directions. This phenomenon reflects exciton transport within the $\nu_T = 1$ condensate, rather than its quasiparticle excitations. We find that quasiparticle transport competes with exciton transport at elevated temperatures, drive levels, and layer separations. This work represents a collaboration with A.D.K. Finck, J.P. Eisenstein, L.N. Pfeiffer and K.W. West.

3:06PM C2.00002 Coulomb Drag and Magnetotransport in Graphene Double Layers[1]

, EMANUEL TUTUC, The University of Texas at Austin — Graphene double layers, a set of two closely spaced graphene monolayers seperated by an ultra-thin dielectric, represent an interesting electron system to explore correlated electron states. We discuss the fabrication of such samples using a layer-by-layer transfer approach, the electron transport in individual layers at zero and in a high magnetic field, and Coulomb drag measurements. Coulomb drag, probed by flowing a drive current in one layer, and measuring the voltage drop in the opposite layer provides a direct measurement of the electron-electron scattering between the two layers, and can be used to probe the electron system ground state. Coulomb drag in graphene, measured as a function of both layer densities and temperature reveals two distinct regimes: (i) diffusive drag at elevated temperatures, above 50 K, and (ii) mesoscopic fluctuations-dominated drag at low temperatures [1, 2]. A second topic discussed here is a technique that allows a direct measurement of the Fermi energy in an electron system with an accuracy independent of the sample size, using a graphene double layer heterostructure. The underlying principle of the technique is that an interlayer bias applied to bring the top layer to the charge neutrality point is equal to the Fermi energy of the bottom layer, which in effect renders the top graphene layer a resistively detected Kelvin probe [3]. We illustrate this method by measuring the Fermi velocity, Landau level spacing, and Landau level broadening in monolayer graphene. Work done in collaboration with S. Kim, I. Jo, J. Nah, D. Dillen, K. Lee, B. Fallahazad, Z. Yao, and S. K. Banerjee.

3:42PM C2.00003 Interaction phenomena and Coulomb drag in graphene-based heterostructures[1]

, ANDRE GEIM, University of Manchester — Double-layer graphene heterostructures with boron nitride as a thin insulating barrier allow us to achieve a strongly interacting regime such that the two Dirac liquids effectively nest within the same plane but can be tuned and measured independently. The experiment reveals many unexpected features that are related to strong excitonic effects and mutual polarization of the graphene layers, which will be discussed in this talk.

[1]In collaboration with Dr. Leonid Ponomarenko and Dr. Roman Gorbachev.

4:18PM C2.00004 Interlayer Coherence and Transport in Quantum Hall Bilayers and Dirac Materials , DMYTRO PESIN, University of Utah — I will discuss two phenomenological descriptions of low-current transport in bilayer quantum Hall system with exciton condensates [1], one based on a Landauer-Buttiker description of Andreev scattering at contacts to coherent bilayers, and one based on a simplified single-parameter p-ology description of the weak to strong interlayer coupling crossover. The Andreev scattering phenomenology is intended to apply when the condensate is well developed and is used to predict current-voltage relationships for a variety of two-contact geometries. I will also apply this formalism to circumstances in which the tunnel current exceeds its critical value and the condensate is time-dependent. The p-ology approach will establish the universal development of large longitudinal drags, even in homogeneous coherent samples, as the condensate weakens and the Hall drag is reduced. Further, I will discuss the interaction-enhanced coherence in layered Dirac systems: two graphene or topological insulator surface-state layers, and the estimates of its strength based on the imaginary-axis gap equations in the random phase approximation [2]. Using a self-consistent treatment of dynamic screening of Coulomb interactions in the gapped phase, I will show that the excitonic gap can reach values on the order of the Fermi energy at strong interactions. The gap will turn out to be a discontinuous function of the interlayer separation and effective fine structure constant, revealing a first-order phase transition between effectively incoherent and interlayer coherent phases.

4:54PM C2.00005 Energy-driven Couomb Drag in Graphene , L.S. LEVITOV, MIT — No abstract available.

Monday, March 18, 2013 2:30PM - 6:06PM –

Session C3 DMP: Invited Session: Metamaterials Ballroom III - David Cahill, University of Illinois

2:30PM C3.00001 James C. McGroddy Prize for New Materials Lecture: Transformation optics shapes metamaterials , JOHN PENDRY, Imperial College London — Metamaterials offer a huge range of new electromagnetic properties: negative refraction, spatial inhomogeneity to name only two. To exploit the possibilities offered in this new world we need a new design tool. Maxwell's equations are exact at the classical level but lack transparency; Snell's law is elegantly visual, an aid to the imagination, but fails to account for many vital aspects of electromagnetism. Transformation optics retains an intuitive appeal, replacing the rays of Snell's law with the field lines of Maxwell whose equations is represents exactly.

3:06PM C3.00002 James C. McGroddy Prize Talk , DAVID SMITH, Duke University — No abstract available.

3:42PM C3.00003 James C. McGroddy Prize Talk - Photonic Metamaterials: Review, Challenging and Opportunities[1] , COSTAS SOUKOULIS, Ames Lab/Iowa State University, USA & IESL-FORTH, Greece — In the last decade, a new area of photonic research has emerged, that has given the ability to produce materials with entirely novel electromagnetic properties. Known as metamaterials (MMs) for their ability to take beyond conventional materials. Clearly, the field of MMs can develop mould-breaking technologies for a plethora of applications, where control over light (or more generally electromagnetic radiation) is a prominent ingredient–among them telecommunications, solar energy harvesting, biological and THz imaging and sensing, optical isolators and polarizers. In this talk, I give an introduction into this emerging field, review recent progress (chiral and 3D MMs, bringing gain to MMs, and what is a good conductor for use in MMs and in plasmonics and Casimir forces) and highlight remaining challenges and opportunities.

4:18PM C3.00004 Three-dimensional Chiral Plasmonic Oligomers , MARIO HENTSCHEL, 4th Physics Institute and Research Center SCoPE, University of Stuttgart — We demonstrate chiral optical response in stacked arrangements of plasmonic nanostructures. We show that three-dimensional arrangements of plasmonic "meta-atoms" only exhibit a chiral optical response if similar plasmonic "atoms" are arranged in a handed fashion as we require resonant plasmonic coupling. Moreover, we demonstrate that such particle groupings, similarly to molecular systems, possess the capability to encode their three-dimensional arrangement in unique and well-modulated spectra, making them ideal candidates for a three-dimensional chiral plasmon ruler. Furthermore, we discuss the onset of a broadband chiral optical response in the wavelength regime between 700 nm and 3500 nm upon charge transfer between the nanoparticles. We show in experiment and simulation that this response is due to the ohmic contact between adjacent particles which causes a strong red-shift of the fundamental mode. The geometrical shape of the resulting fused particles allows for efficient excitation of higher order modes. Calculated spectra and field distributions confirm our interpretation and show a number of interacting plasmonic modes. Finally, we will discuss plasmonic diastereomers which consist of multiple chiral centers. We find that the chiral optical response of the composite molecules can be traced back to the properties of the constituting building blocks. We demonstrate that the optical response of complex chiral plasmonic systems can be decomposed and understood in terms of fundamental building blocks, offering simple and straightforward design rules for future applications such as chiral optical elements and enantiomer sensors.

4:54PM C3.00005 TBD , XIANG ZHANG, University of California-Berkeley — No abstract available.

5:30PM C3.00006 TBD , MARTIN WEGENER, Karlsruhe Institute of Technology — No abstract available.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C4 FIAP: Invited Session: Industrial Physics Forum: Frontiers in Nanomanufacturing

Ballroom IV - Robert Celotta, National Institute of Standards and Technology

2:30PM C4.00001 Frontiers of Nanomanufacturing: An Overview , JAMES LIDDLE, Center for Nanoscale Science and Technology, NIST — Nanomanufacturing in its current state encompasses a huge range of materials, products and processes at different levels of maturity and scale. The common thread uniting these disparate activities is that the cost of the methods used in manufacturing - including metrology - must be consistent with both the price the products command and the size of the available market to be economically viable. In this talk I will give examples of how the complexity of the final product and its value dictate what type of nanomanufacturing approach is appropriate, using semiconductor manufacturing as a baseline against which to compare the production of items such as carbon nanocomposites, nanophotonic structures and DNA constructs. In particular, I will describe the need for and progress towards new metrology techniques that can provide nanoscale information, but do so at rates consistent with the high-volume manufacturing of low-cost products.

3:06PM C4.00002 New Computing Devices and the Drive toward Nanometer-scale Manufacturing , THOMAS THEIS, IBM Research (on assignment to Semiconductor Research Corp.) — In recent decades, we have become used to the idea of exponentially compounding improvements in manufacturing precision. These improvements are driven in large part by the economic imperative to continuously shrink the devices of information technology, particularly the Complementary Metal Oxide Semiconductor (CMOS) field-effect transistor. However, CMOS technology is clearly approaching some important physical limits. Since roughly 2003, the inability to reduce supply voltages according to constant-field scaling rules, combined with economic constraints on areal power density and total power, has forced designers to limit clock frequencies even as devices have continued to shrink. New channel materials, new device structures, and novel circuits cannot fundamentally alter this new status quo. The device physics must change in a more fundamental way if we are to realize fast digital logic with very low power dissipation. The continued vitality of the information technology revolution and the continued push of manufacturing precision toward nanometer dimensions, will depend on it. Fortunately, there is no shortage of new digital switch concepts based on physical principles which avoid the fundamental voltage-scaling limit of the field-effect transistor. The Nanoelectronics Research Initiative (NRI) is a consortium of leading semiconductor companies established in 2005 to guide and fund fundamental research at U.S. universities with the goal of finding the "next switch" to replace the CMOS transistor for storing and manipulating digital information. The National Institute of Standards and Technology (NIST) and the National Science Foundation (NSF) have partnered with NRI to fund this research. To date, NRI has funded the exploration of many novel device concepts, and has guided research comparing the capabilities of these devices. Although no single device has yet emerged as a clear winner with the potential to eclipse the field-effect transistor, results are sufficiently promising that member companies have recently renewed their commitment to NRI. Based on the learning to date, a vision for the next five years of research has emerged.

3:42PM C4.00003 Atomic-Scale Electronics , MICHELLE SIMMONS, University of New South Wales — Down-scaling has been the leading paradigm of the semiconductor industry since the invention of the first transistor in 1947. However miniaturization will soon reach the ultimate limit, set by the discreteness of matter, leading to intensified research in alternative approaches for creating logic devices. We will present single atom transistors where we can measure both the charge and spin of individual dopants and discuss long term architectures to exploit their unique characteristics.

4:18PM C4.00004 Nanoscale construction with DNA , SHAWN DOUGLAS, UCSF — The programmability of DNA makes it an attractive material for constructing intricate nanoscale shapes. One method for creating these structures is DNA origami, in which a multiple-kilobase single-stranded "scaffold" is folded into a custom nanoscale shape by interacting with hundreds of short oligonucleotide "staple" strands. I will talk about our efforts to realize demand-meeting applications of this method, including our recent development of nanoscale devices to mimic cell-signaling stimulation carried out by our own immune systems.

4:54PM C4.00005 Manufacturing for Terawatt-Scale Energy Applications[1] , HARRY ATWATER, California Institute of Technology — Future energy conversion devices will make extensive use of nanostructured materials that must be manufactured at a scale compatible with terawatt-scale deployment. Specifically, future ultrahigh efficiency photovoltaic devices and modules will likely have little in common with today's photovoltaic technology but instead will be essentially complex optical integrated circuits with microscale and nanoscale critical dimensions for efficient optical spectrum splitting, light absorption and carrier transport. The challenge for nanomanufacturing is to realize the fabrication of these sophisticated device architectures with nanoscale features in high-volume low-cost commodity fabrication processes. I will describe examples of practical and scalable approaches to large-scale nanophotonic fabrication using recent advances in the research and commercial development. One example is epitaxial liftoff of thin-film single-crystal Si and III–V compound semiconductor absorbers, and layer-transfer printing techniques for single crystal film assembly of lifted film structures. Another is substrate conformable soft-imprint lithography provides a scalable method for the synthesis of low-cost large-area arrays of nano-patterned light-trapping structures or structures with engineered optical density of states. It is now well established that soft-imprint lithography has a deep-subwavelength resolution, maintained over a large area. Directions for future research and applications to other energy technologies will be surveyed.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Materials for Energy Applications 301 - Richard Hennig, Cornell University

2:30PM C5.00001 Computational materials design for energy applications[1] , VIDVUDS OZOLINS, Department of Materials Science and Engineering, University of California, Los Angeles, California 90095-1595, USA — General adoption of sustainable energy technologies depends on the discovery and development of new high-performance materials. For instance, waste heat recovery and electricity generation via the solar thermal route require bulk thermoelectrics with a high figure of merit (ZT) and thermal stability at high-temperatures. Energy recovery applications (e.g., regenerative braking) call for the development of rapidly chargeable systems for electrical energy storage, such as electrochemical supercapacitors. Similarly, use of hydrogen as vehicular fuel depends on the ability to store hydrogen at high volumetric and gravimetric densities, as well as on the ability to extract it at ambient temperatures at sufficiently rapid rates. We will discuss how first-principles computational methods based on quantum mechanics and statistical physics can drive the understanding, improvement and prediction of new energy materials. We will cover prediction and experimental verification of new earth-abundant thermoelectrics, transition metal oxides for electrochemical supercapacitors, and kinetics of mass transport in complex metal hydrides.

[1]Research has been supported by the US Department of Energy under grant Nos. DE-SC0001342, DE-SC0001054, DE-FG02-07ER46433, and DE-FC36-08GO18136.

3:06PM C5.00002 Design and synthesis of a crystalline LiPON electrolyte[1] , N.A.W. HOLZWARTH, KEERTHI SENEVIRATHNE, CYNTHIA S. DAY, ABDESSADEK LACHGAR, Wake Forest U., MICHAEL D. GROSS, Bucknell U. — In the course of a computation study of the broad class of lithium phosphorus oxy-nitride materials of interest for solid electrolyte applications, Du and Holzwarth,[2] recently predicted a stable crystalline material with the stoichiometry Li_2PO_2N. The present paper reports the experimental preparation of the material using high temperature solid state synthesis and reports the results of experimental and calculational characterization studies. The so-named SD-Li_2PO_2N crystal structure has the orthorhombic space group $Cmc2_1$ with lattice constants a=9.0692(4) Å, b=5.3999(2) Å, and c=4.6856(2) Å. The structure is similar but not identical to the predicted structure, characterized by parallel arrangements of anionic phosphorus oxy-nitride chains having planar P−N−P−N backbones. Nitrogen 2pπ states contribute to the strong bonding and to the chemical and thermal stablility of the material in air up to 600° C and in vacuum up to 1050° C. The measured Arrhenius activation energy for ionic conductivity is 0.6 eV which is comparable to computed vacancy migration energies in the presence of a significant population of Li^+ ion vacancies.

[1]Supported by NSF grant DMR-1105485 and by a grnat from the Wake Forest University Center for Energy, Environment, and Sustainability.

3:18PM C5.00003 Proton Diffusion Model for High-Throughput Calculations , PANDU WISESA, TIM MUELLER, Department of Materials Science and Engineering, Johns Hopkins University — Solid oxide fuel cells (SOFCs) have many advantages over other fuel cells with high efficiency, myriad fuel choices, and low cost. The main issue however is the high operating temperature of SOFCs, which can be lowered by using an electrolyte material with high ionic conductivity, such as proton conducting oxides. Our goal is to identify promising proton-conducting materials in a manner that is time and cost efficient through the utilization of high-throughput calculations. We present a model for proton diffusion developed using machine learning techniques with training data that consists of density functional theory (DFT) calculations on various metal oxides. The built model is tested against other DFT results to see how it performs. The results of the DFT calculations and how the model fares are discussed, with focus on hydrogen diffusion pathways inside the bulk material.

3:30PM C5.00004 Atomistic level description of phase diagram of gas clathrate hydrates with complex gas compositions[1] , R. BELOSLUDOV, H. MIZUSEKI, IMR, Tohoku University, Y. KAWAZOE, NIHC, Tohoku University, O. SUBBOTIN, V. BELOSLUDOV, Nikolaev Institute of Inorganic Chemistry, SB RAS — An approach has been realized that allows us to construct a p-T phase diagrams of various gas hydrates, three-dimensional hydrogen-bonded water structures in which water molecules arrange themselves in a cage-like (host) structure around gas (guest) molecules, with complex gas compositions [1-2]. In order to evaluate the parameters of weak interactions, a TDDFT formalism and LDA technique entirely in real space have been implemented for calculations of vdW dispersion coefficients for atoms within the all-electron mixed-basis approach. The combination of both methods enables one to calculate thermodynamic properties of clathrate hydrates without resorting to any empirical parameter fittings. Using the proposed method it is possible not only confirm the existing experimental data but also predict the unknown region of thermodynamic stability of clathrate hydrates, and also propose the gas storage ability as well as the gas composition for which high-stability region of clathrate hydrates can be achieved. The proposed method is quite general and can be applied to the various non-stoichiometric inclusion compounds with weak guest-host interactions.

3:42PM C5.00005 Materials for Alternative Energies: Computational Materials Discovery and Crystal Structure Prediction , CHRIS WOLVERTON, Northwestern University — Many of the key technological problems associated with alternative energies may be traced back to the lack of suitable materials. The materials discovery process may be greatly aided by the use of computational methods, particular those atomistic methods based on density functional theory. In this talk, we present an overview of recent work on energy-related materials from density-functional based approaches. We have developed novel computational tools which enable accurate prediction of crystal structures for new materials (using both Monte Carlo and Genetic Algorithm based approaches), materials discovery via high-throughput, data mining techniques, and automated phase diagram calculations. We highlight applications in the area of Li battery materials and hydrogen storage materials.

4:18PM C5.00006 Multigap Semiconducting ferroelectric perovskites , LAI JIANG, ILYA GRINBERG, FENGGONG WANG, PETER DAVIES, ANDREW RAPPE, University of Pennsylvania — The energy conversion efficiency of a solar cell is directly related to the band gap of the material. By doping ferroelectric perovskites with Bi^{5+} on the B-site, we propose low band-gap materials suitable for bulk photovoltaic effect and related solar applications.Our DFT calculations indicate that the low-lying $6s$ empty states of the electronegative Bi atom produce empty isolated bands in the gap of the parent materials, effectively lowering the band gap by 1$\sim$2eV in various perovskites. Ferroelectricity (and therefore inversion symmetry breaking) weakens but survives upon doping, which enables the "shift current" mechanism for photocurrent generation, while the decreased band gap helps absorb low energy photons in the visible range. Furthermore, the existence of multiple band gaps allows for solar conversion devices with efficiency beyond the traditional Shockly-Queisser limit, in which successive photon excitations result in carriers with higher energy than a single-step excitation would achieve.

4:30PM C5.00007 Search for highly absorbing thin-film photovoltaic absorbers in the system Cu-V-VI from first principles calculations[1] , LIPING YU, University of Colorado at Boulder/National Renewable Energy Laboratory, ROBERT S. KOKENYESI, DOUGLAS A. KESZLER, Oregon State University, ALEX ZUNGER, University of Colorado at Boulder — To enable high-efficiency solar conversion, thin-film absorbers need to have strong absorption of photons across the solar spectrum. While the $CuInSe_2$-like materials have strong absorption, their measured rise in absorption near the band gap necessitates the use of rather thick films. This thickness, coupled with the relatively low abundance of In, potentially limits the scalability of this technology to the terawatt scale. Here we screen and assess absorption properties of $\sim$40 earth-abundant Cu-V-VI (V = P,As,Sb,Bi) materials, based on the recently proposed selection metric of "Spectroscopic Limited Maximum Efficiency" (SLME) [PRL. 108, 068701 (2012)]. This metric depends explicitly on calculated absorption spectra and accounts for different types of optical transitions near the absorption threshold. According to the SLME values calculated from 1st-principles quasiparticle GW theory, we propose five Cu-V-VI candidate thin-film absorber materials that have optical absorption stronger than $CuInSe_2$, which can be ascribed to the enhancement of the density of states near the conduction band maximum. The finding leads to refined design principles in support of the continuing quest for optimal absorber materials.

[1]Supported by the U.S. DOE, EFRC Center for Inverse Design.

4:42PM C5.00008 Accurate surface ionization potentials and electron affinities of semiconductors and insulators, a step toward water splitting predictions[1] , VLADAN STEVANOVIC, Colorado School of Mines, STEPHAN LANY, National Renewable Energy Laboratory, ALEX ZUNGER, University of Colorado Boulder — Design of semiconductors for water splitting requires knowledge of the position of band edges relative to the water redox potential. This can be achieved by predicting materials' ionization potentials (IPs) and electron affinities (EAs). We recently developed a predictive method combining different electronic structure techniques, which is able, as will be demonstrated, to reproduce IPs and EAs of a broad range of materials including standard semiconductors (GaAs, ZnO, CdS,...) and transition metal compounds (TiO2, MnO,...). Achieved accuracy is within 0.1-0.2 eV from the measured photoemission data. We use GGA(+U) to calculate the electronic structure of bulk systems and their surfaces leading to the alignment of the bulk GGA(+U) band edges with the vacuum. The many-body, quasiparticle GW method is used to calculate shifts of the bulk band edges with respect to the underlying GGA(+U) formalism. Combining GGA(+U) and GW results in accurate IPs and EAs. In the case of transition metal compounds additional external d-potentials are included in the selfconsistent GW cycle to account for the inaccurate position of the transition metal d-orbitals relative to s and p-orbitals, leading to accurate IPs and EAs also in these, for the electronic structure methods problematic, cases.

[1]Work supported as part of the Center for Inverse Design, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences

4:54PM C5.00009 First principle studies of doping effects on the electronic and geometric structures of graphitic C3N4 , SEBASTIAN ZULUAGA, SERGEY STOLBOV, University of Central Florida — Layered carbon nitride g-C3N4 is a promising material as a photo-anode for the H production from water. By doping, the band gap (2.7 eV) can be tuned to the value optimal for efficient absorption of visible light irradiation. We present here our first principle computational study of the effects of doping with B, P and S on the geometric and electronic structures of g-C3N4 and compare them to experimental results. We have evaluated within density functional theory the energetics of various doping scenarios in terms of both thermodynamics and kinetics, and selected the energetically most favorable structures. Our calculations reveal important details of valence charge density redistribution upon the doping. The doping effect on the electronic density of states (DOS), in particular on band gap width, has been evaluated using an accurate GW method. We find the DOS to strongly depend on the doping geometry. The detailed analysis of the projected DOS provides significant insight into the mechanism underlying modification of the electronic structure upon doping.

5:06PM C5.00010 Stabilizing and enhancing activity of Ag as a catalyst for oxygen redaction reaction on hydrogen fuel cell cathodes[1] , SERGEY STOLBOV, MARISOL ALCANTARA ORTIGOZA, University of Central Florida — Progress in searching for cost-effective and highly active catalysts for the oxygen reduction reaction (ORR) on hydrogen fuel cell cathodes is hindered by the fact that only a few elements (expensive and scarce Pt, Ir, Au) do not dissolve in the reaction environment (acidic medium at the expected operating potential +0.8 to +1.0 V vs SHE). Yet, in this work, we explore silver as an active element for the ORR catalysts. Although the dissolution potential (DP) of elemental Ag is 0.8 V, we rely on our finding [1] that binding of a metal monolayer (ML) to a reactive substrate can significantly increase its DP. Using our approach [1], we select Ag/Ru/W, Ag/Nb, and Ag/Ta as promising candidates for the ORR catalysts (where Ag and Ru are MLs). Our evaluation of DP within density functional theory (DFT) shows that, indeed, in the selected structures, DP of Ag significantly increases as compared to that of Ag(111) and, in the case of Ag/Nb, even exceeds that of Pt. The ORR free-energy diagrams calculated within DFT suggest that the above systems are more active toward ORR than Pt. We thus predict here three highly active and truly cost-effective ORR catalysts. [1] S. Stolbov, M. Alcantara Ortigoza, J. Phys. Chem. Letts. 3, 463 (2012).

5:18PM C5.00011 Two dimensional N-containing carbon materials for oxygen reduction reaction , YEXIN FENG, ZHENPENG HU, LIXIN ZHANG, School of Physics, Nankai University — Seeking Pt replacement catalysts for cathode oxygen reduction reaction (ORR) is very important for the application of some new energy technologies like fuel cells and lithium-air batteries. N-doped graphene and carbon nitride sheets are two kinds of promising materials. For the N-doped graphene, it is found that nitrogen clusters other than isolated substitutionals are the active sites for oxygen reduction. Clusters with three or four N atoms are found to be the most active. Codoping boron (or Fe, Co) can effectively stabilize these high energy clusters while keep the cluster's high activity. For the carbon nitride sheets, in the C:N ratio range of 2.0-3.0, they are stable enough and can potentially catalyze the oxygen reduction as efficiently as Pt. It is revealed that the concentration of nitrogen can tune the Fermi level of the material and thus the catalytic property. The catalytic sites are located at those carbon atoms with special configurations rather than the nitrogen atoms. These results are helpful in designing N-containing carbon materials for ORR.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C6 DMP: Focus Session: Hexagonal BN, Graphene, and Graphene Oxide Synthesis II

302 - Saikat Talapatra, Southern Illinois University at Carbondale

2:30PM C6.00001 Growth of Single-Layer Graphene Using Alcohol Catalytic Chemical Vapor Deposition on Cu Substrate , XIAO CHEN, PEI ZHAO, BO HOU, ERIK EINARSSON, SHOHEI CHIASHI, SHIGEO MARUYAMA, Department of Mechanical Engineering, The University of Tokyo — CVD on metal substrates has been proved to be effective in the synthesis of graphene. Compared with commonly used carbon sources methane and ethylene, ethanol is safe and easy to use, thus is advantageous as an alternative graphene growth precursor. Here we report a systematic work of graphene growth on Cu substrate using ethanol precursor. Typically, Cu films were exposed to 100 sccm ethanol flow at 100 Pa and 1000°C for 20 seconds to yield a continuous single-layer graphene film. Characterization using SEM and Raman spectroscopy indicated that the graphene films were homogeneous and of high quality. We conducted a parametric study to prove that high-quality graphene could be grown when the reaction temperature is 900 to 950°C and the pressure is lower than 100 Pa. Moreover, graphene growth at lower pressure showed a strong tendency to be self-limiting, resulting in only single-layer graphene even with longer CVD duration (30 min).

2:42PM C6.00002 Tailoring Graphene Morphology and Orientation on Cu(100), Cu(110), and Cu(111) , ROBERT JACOBBERGER, MICHAEL ARNOLD, University of Wisconsin-Madison — Graphene CVD on Cu is phenomenologically complex, yielding diverse crystal morphologies, such as lobes, dendrites, stars, and hexagons, of various orientations. We present a comprehensive study of the evolution of these morphologies as a function of Cu surface orientation, pressure, H_2:CH_4, and nucleation density. Growth was studied on ultra-smooth, epitaxial Cu films inside Cu enclosures to minimize factors that normally complicate growth. With low H_2:CH_4, Mullins-Sekerka instabilities propagate to form dendrites, indicating transport limited growth. In LPCVD, the dendrites extend hundreds of microns in the 100, 111, and 110 directions on Cu(100), (110), and (111) and are perturbed by twin boundaries. In APCVD, multiple preferred dendrite orientations exist. With increasing H_2:CH_4, the dendritic nature of growth is suppressed. In LPCVD, square, rectangle, and hexagon crystals form on Cu(100), (110) and (111), reflecting the Cu crystallography. In APCVD, the morphology becomes hexagonal on each surface. If given ample time, every growth regime yields high-quality monolayers with D:G Raman ratio <0.1. The understanding gained here provides a framework to rationally tailor the graphene crystal morphology and orientation.

2:54PM C6.00003 Van der Waals MBE growth of graphene on dielectric substrates[1] , SHENG WANG, ULRICH WURSTBAUER, Columbia University, NY, JORGE M. GARCIA, Instituto de Microelectrónica de Madrid. CNM. CSIC. Spain, LARA FERNANDES DOS SANTOS, LEI WANG, ANTONIO LEVY, JUNGSIK PARK, CORY R. DEAN, Columbia University, NY, LOREN N. PFEIFFER, Princeton University, NJ, JAMES HONE, ARON PINCZUK, Columbia University, NY — Graphene growth on dielectric substrates has potential to enable new kinds of devices and applications. We explore graphene growth by direct deposition of carbon on different dielectric substrates in a MBE environment. Here we consider h-BN and sapphire substrates. The quality of fabricated graphene layers depends on growth conditions such as carbon deposition rate, substrate temperature and total amount of deposited carbon. Characterizations by spatially resolved Raman spectra and AFM images suggest the formation of high quality graphene. On h-BN substrates, single layer growth occurs as nano-domains. On sapphire, large area growth happens with monolayer thickness fluctuations. These results are consistent with a van der Waals growth mode of graphene on dielectric substrates.

3:06PM C6.00004 Kink kinetics of graphene growth on Ir(111) , PAUL C. ROGGE, Department of Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Lab, SHU NIE, KEVIN F. MCCARTY, NORMAN C. BARTELT, Sandia National Laboratories, Livermore, CA, OSCAR D. DUBON, Department of Materials Science and Engineering, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Lab — Graphene growth of aligned domains on Ir(111) and Ru(0001) is controlled by the attachment of clusters of carbon adatoms. Here we study the growth of rotational variants on Ir(111) and show that the growth is dependent on both cluster attachment and kink kinetics. We simultaneously measure the growth velocity of individual facets and the local concentration of carbon adatoms. The faceted domains tend to lie along the equilibrium zigzag or armchair direction. As the carbon adatom concentration increases, the facets deviate from their equilibrium orientation. This increases the kink density, allowing faster growth. The kink density is a function of the carbon adatom supersaturation. We will discuss how these findings account for the different growth velocities between aligned and rotated domains. This work was supported by the Director, Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, of the U.S. Department of Energy Contract No. De-Ac04-94AL85000 (SNL). 3:18PM C6.00005 Unoccupied states on Graphene/Cu(111) system[1] , SHENGMIN ZHANG, XUEFENG CUI, CONG WANG, HRVOJE PETEK[2], University of Pittsburgh, Department of Physics and Astronomy — Based on the Graphene/Cu(111) system we prepared by the chemical vapor deposition method, we explored the surface states and image potential states by two photon photoemission (2PPE) and angle-resolved photoemission using ultrashort laser pulses. Graphene on the Cu(111) surface can be recognized through 2PPE spectra, based on the theoretical band structure, which showed clear angle dispersions under different wavelength measurements. In addition, the surface state of Cu(111) could also be observed in the 2PPE spectra, and under some certain wavelength, there is a strong resonance of the surface state on Cu(111) and the image potential state on Graphene. With the angle-resolved photoemission, the effective masses of the surface state and image potential state were obtained by simply fitting the dispersion curves.

3:30PM C6.00006 In situ observation of the graphene domain shape on Ni(111) single crystal films , MEIFANG LI, Brown University, JIEBING SUN, Michigan State University, JAMES HANNON, RUDOLF TROMP, IBM T.J. Watson Research Center, ERIC CHASON, Brown University — Graphene has great potential application in electronics due to its high carrier mobility. Graphene can be grown via chemical vapor deposition (CVD) on many metal surfaces, with Cu and Ni being the most studied. Ni(111) is particularly interesting because graphene is epitaxial and is strongly bound to the substrate. As we show, the epitaxial relationship strongly influences the domain shape. Here we describe in situ LEEM experiments to determine the equilibrium shape of graphene domains grown via dissolution and segregation at elevated temperature. We used a novel "real space diffraction" method, coupled with diffracted intensity calculations, to determine the crystallographic orientation of the graphene domains relative to the Ni(111) substrate. We find that the equilibrium shape supports zig-zag edges. However, the domain shape is triangular, rather than hexagonal, indicating that only one type of zig-zag edge is favored.

3:42PM C6.00007 Electrical Transport Properties of Chemically Reduced Graphene Oxide Thin Films , BALEESWARAIAH MUCHHARLA, Southern Illinois University Carbondale, NARAYANAN THARANGATTU NARAYANAN, KAUSHIK BALAKRISHNAN, PULICKEL AJAYAN, Rice University, SAIKAT TALAPATRA, Southern Illinois University Carbondale, SOUTHERN ILLINOIS UNIVERSITY-CARBONDALE TEAM, RICE UNIVERSITY COLLABORATION — We will report on synthesis and electrical characterization of reduced graphene oxide (rGO) obtained from graphene oxide (GO) in ascorbic acid. Electrical transport on thin film devices made from these samples was investigated in a wide range (50 K to 400 K) of temperature. We find that the between the temperature range (150 K to 400 K) these samples show Arrhenius-like temperature dependence. At low temperatures, (50 K to 150 K) variable range hopping (VRH) transport of electrons in a two-dimensional electron system was observed for these samples. The effect of magnetic field on the electrical transport on these materials will presented and discussed.

3:54PM C6.00008 Electrical Characterization of Graphene Flakes Synthesized Using Liquid Phase Exfoliation of Graphite in Isopropyl Alcohol , SAIKAT TALAPATRA, BALEESWARAIAH MUCHHARLA, MITCHELL CONNOLLY, ANDREW WINCHESTER, SUJOY GHOSH, Southern Illinois University Carbondale, SWASTIK KAR, Northeastern University, Boston, SOUTHERN ILLINOIS UNIVERSITY CARBONDALE TEAM, NORTHEASTERN UNIVERSITY, BOSTON COLLABORATION — Liquid-phase exfoliation processes for synthesis of nano structures is often a simpler route to get functional nanomaterials in large scale. Here we will report on the synthesis of graphene flakes using exfoliation of bulk graphite in isopropyl alcohol. We will also present electrical characterization of thin film devices made from these exfoliated flakes. Temperature dependence of resistance performed for 10K $<$T $<$300K shows a slow linear increase in resistance with decrease in temperature. Behavior of thin film devices made from these exfoliated flakes under electrochemical gating environment will be presented and discussed.

4:06PM C6.00009 Transport properties of high-quality reduced graphene oxide , M. ENZELBERGER, Lehrstuhl für Experimentalphysik, Universität Erlangen, S. EIGLER, Department of Chemistry and Pharmacy, and Institute of Advanced Materials and Processes (ZMP), Universität Erlangen, P. HOFFMANN, Lehrstuhl für Experimentalphysik, Universität Erlangen, S. GRIMM, A. HIRSCH, Department of Chemistry and Pharmacy, and Institute of Advanced Materials and Processes (ZMP), Universität Erlangen, P. MÜLLER, Lehrstuhl für Experimentalphysik, Universität Erlangen — Chemical production of graphene, especially reducing graphene oxide has gained a lot of interest in recent years. Yet the transport properties of such materials are usually not compatable to those of graphene. We have found a way to overcome this problem using a modification of the standard Hummer's method. Single flakes of reduced graphene oxide have been investigated. The graphene oxide was deposited onto a SiO_2/Si substrate and subsequently reduced using hydrogen iodine. The resulting reduced graphene oxide samples were patterned by electron beam lithography. We have characterized the quality of the samples by combining Raman spectroscopy and Hall mobility measurements in magnetic fields up to 14 T and temperatures down to 0.3 K. High-quality samples had a Raman D/G ratio of better than 1 and showed Hall mobilities exceeding 1000 cm^2/Vs. This is nearly two orders of magnitude higher than what is known for standard reduced graphene oxide. The best samples even show Shubnikov-de Haas oscillations and Hall plateaus. S. Eigler, Christoph Dotzer, Andreas Hirsch, Michael Enzelberger, Paul Müller, *Chem. Mater.,* **24** 1276 (2012)

4:18PM C6.00010 Probing Charge Migration in Progressively Reduced Graphene Oxide using Electrostatic Force Microscopy , SIBEL EBRU YALCIN, Los Alamos National Laboratory, CHARUDATTA GALANDE, Rice University, HISATO YAMAGUCHI, GAUTAM GUPTA, Los Alamos National Laboratory, PULICKEL AJAYAN, Rice University, ANDREW DATTELBAUM, STEPHEN DOORN, ADITYA MOHITE, Los Alamos National Laboratory — The discovery of graphene and tremendous attention it took in the last few years led to the discovery of graphene oxide (GO) for the large scale production of graphene. GO provides an ideal platform to manipulate and control its chemical structure, optoelectronic properties and ionic conductivity for a wide range of applications. Therefore, it is critical to understand the physical and electrical properties of GO that are highly dependent on the density and nature of functional groups. Here, using electrostatic force microscopy (EFM), we inject charge and directly probe the charge migration as the GO is progressively reduced (RGO). EFM results on GO flakes indicate that the injected charge is completely localized within the plane of GO. However, with the increasing degree of reduction, the injected charge rapidly delocalizes over a few microns until it ends up at the edge of the flakes. The results suggest that as we go from GO to RGO, there are more percolating pathways of sp2 that are formed that act as conduits for charge migration. Our results are consistent with the observed photoluminescence quenching on GO flakes measured as a function of reduction from GO to RGO.

4:30PM C6.00011 ABSTRACT WITHDRAWN –

4:42PM C6.00012 Probing Interfacial Processes on Graphene Surface by Mass Detection[1] , NURBEK KAKENOV, COSKUN KOCABAS, Bilkent University — In this work we studied the mass density of graphene, probed interfacial processes on graphene surface and examined the formation of graphene oxide by mass detection. The graphene layers were synthesized by chemical vapor deposition method on copper foils and transfer-printed on a quartz crystal microbalance (QCM). The mass density of single layer graphene was measured by investigating the mechanical resonance of the QCM. Moreover, we extended the developed technique to probe the binding dynamics of proteins on the surface of graphene, were able to obtain nonspecific binding constant of BSA protein of graphene surface in aqueous solution. The time trace of resonance signal showed that the BSA molecules rapidly saturated by filling the available binding sites on graphene surface. Furthermore, we monitored oxidation of graphene surface under oxygen plasma by tracing the changes of interfacial mass of the graphene controlled by the shifts in Raman spectra. Three regimes were observed the formation of graphene oxide which increases the interfacial mass, the release of carbon dioxide and the removal of small graphene/graphene oxide flakes.

4:54PM C6.00013 Evolution of Thermally Annealed Graphitic Amorphous Carbon toward Graphene: Structure, Vibrational Dynamics, Electron Emission and Band Gap , JR DENNISON, JODIE GILLESPIE, Utah State University, STERLING SMITH, General Atomics — Standard structural models of graphitic amorphous carbon (g-C)—a ubiquitous form of disordered carbon present in the production of graphenes, nanotubes, fullerenes, diamond films, and graphite—postulate that g-C is composed primarily of sp^2-bonded nearly planar rafts with a structural distribution of carbon rings with 4 to 8 atoms. An embedded ring approach is used to model vibrational dynamics for planar disordered materials and determine the structural evolution of thermally annealed g-C, based on fits to Raman spectra of g-C annealed to temperatures ranging from 22 °C to 1050 °C. This vibrational model assumes that constituent atoms of a material are arranged in n-membered planar rings embedded in the effective medium, a continuous random network of atoms. From the relative intensities of the different frequency peaks resulting from in-plane normal modes, our procedures provide quantitative ring statistics for the structure of g-C. Unannealed g-C is found to have many 5- and 7-membered rings, but the fraction of 6-membered rings increases with annealing temperature consistent with the known result that g-C evolves to nanocrystalline graphite under high T annealing. The structural model is used to explain measurements of the band gap and electron emission of g-C as it is thermally annealed toward a graphene-like structure.

5:06PM C6.00014 Gold Decorated Graphene for Rapid Dye Reduction and Efficient Electro Catalytic Oxidation of Ethanol , R.S. SAI SIDDHARDHA, LAKSHMAN KUMAR V, Sri Sathya Sai Institute of Higher Learning, A. KANIYOOR, IITMadras, R. PODILA, Clemson University, V.S. MUTHU KUMAR, K. VENKATARAMANIAH, Sri Sathya Sai Institute of Higher Learning, S. RAMAPRABHU, IITMadras, A. RAO, Clemson University, S.S. RAMAMURTHY, Sri Sathya Sai Institute of Higher Learning, India, CLEMSON UNIVERSITY TEAM, SRI SATHYA SAI INSTITUTE OF HIGHER LEARNING TEAM, IITMADRAS TEAM — A well known disadvantage in fabrication of metal-graphene composite is the use of surfactants that strongly adsorb on the surface and reduce the performance of the catalyst. Here, we demonstrate a novel one pot synthesis of gold nanoparticles (AuNPs) by laser ablation of gold strip and simultaneous decoration of these on functionalized graphene derivatives. Not only the impregnation of AuNPs was linker free, but also the synthesis by itself was surfactant free. This resulted in *in-situ* decoration of pristine AuNPs on functionalized graphene derivatives. These materials were well characterized and tested for catalytic applications pertaining to dye reduction and electrooxidation. The catalytic reduction rates are 1.4×10^2 and 9.4×10^2 times faster for Rhodamine B and Methylene Blue dyes respectively, compared to earlier reports. The enhanced rate involves synergistic interplay of electronic relay between AuNPs and the dye, also charge transfer between the graphene system and dye. In addition, the onset potential for ethanol oxidation was found to be more negative $\sim$ 100 mV, an indication of its promising application in direct ethanol fuel cells.

5:18PM C6.00015 Colloidal Stability of Graphene Oxide Nanosheets in Aqueous Solutions , JANICE WYNN GUIKEMA, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD, YUNG-LI WANG, KAI LOON CHEN, Department of Geography and Environmental Engineering, Johns Hopkins University, Baltimore, MD — Carbon-based nanomaterials are increasingly used in commercial products as well as in research and industrial applications. Due to its extraordinary properties, graphene has attracted intense research interest and has been demonstrated in many potential applications including solar cells, conductive ink, and transistors. Graphene oxide has also been studied extensively and has been used to produce biocompatible antibacterial paper. Chemical reduction of graphene oxide is commonly used to produce inexpensive graphene in large quantities. With the increasing use of graphene and graphene oxide in consumer products, these nanomaterials may inevitably be released to aqueous systems, resulting in potential risk to environmental ecosystems and human health. The fate and mobility of graphene and its oxides in aquatic systems is dependent on their colloidal stability. We will discuss our study of the early-stage aggregation kinetics of graphene oxide in aqueous solutions. We prepared a suspension of single-layer graphene oxide nanosheets in water and used time-resolved dynamic light scattering to study the influence of electrolytes and pH on the aggregation kinetics of the nanosheets. Atomic force microscopy was employed to further examine the graphene oxide nanosheets.

Session C7 DMP: Focus Session: Graphene Devices III 303 - Monica Allen, Harvard University

2:30PM C7.00001 Rectification at graphene-semiconductor interfaces[1] , ARTHUR HEBARD, Department of Physics, University of Florida, Gainesville FL 32611-8440 — It is now widely recognized that interface between graphene and many semiconductors forms Schottky barriers with rectifying properties. Our work in this area at the University of Florida began in 2009 with our discovery that bulk semimetal graphite when simply pressed against Si, GaAs and 4H-SiC semiconductor substrates readily formed Schottky barriers. Since graphite comprises Bernal-stacked layers of graphene, then the outermost layer, a single sheet of graphene, in contact with the semiconductor plays a major role in the formation of the Schottky barrier. In this talk we follow up on this early work and report on the unusual physics and promising technical applications associated with the formation of Schottky barriers at the interface of graphene and conventional semiconductors. Much of the phenomenology is similar to what is seen with graphite/semiconductor Schottky barriers but with the additional advantages that graphene is flexible, transparent and has a Fermi energy that can be more easily tuned either positively or negatively with respect to the neutrality point by electric fields or chemical doping. Our junctions are fabricated by mechanically transferring chemical vapor deposited graphene onto n-type Si, GaAs, 4H-SiC or GaN semiconductor substrates and takes advantage of the strong van der Waals attraction that is accompanied by charge transfer across the interface and the formation of a rectifying (Schottky) barrier. Using current-voltage (I-V), capacitance-voltage (C-V) and Raman measurements we find that thermionic emission theory in conjunction with the Schottky-Mott model within the context of bond-polarization theory provides a surprisingly good description of the electrical properties. We will discuss a number of applications including diode operation to temperatures as high as 550 K, hole doping and associated Fermi level shifts induced by overcoating the graphene with a transparent layer of polymer (TFSA), and demonstration of solar cells with power conversion efficiencies approaching 9%.

3:06PM C7.00002 Surface functionalization on graphene through chlorination , XU ZHANG, YI SONG, ALLEN HSU, KI KANG KIM, JING KONG, MIT EECS, MILDRED DRESSELHAUS, MIT EECS & MIT Physics, TOMAS PALACIOS, MIT EECS — Since graphene is an all-surface material, surface functionalization provides effective methods to engineer its electronic properties. Here, we demonstrate that exposure of graphene devices to chlorine plasma in an electron cyclotron resonance (ECR) plasma etcher is an effective way to decrease its sheet resistance, engineer its C/Cl ratio and control the interaction between chlorine and carbon atoms.. First, conductivity of chlorinated graphene increases, due to the hole doping induced by the chlorine plasma. This is further confirmed by the Hall-effect measurements: the hole concentration increased from about 5×10^{12} cm^{-2} to around 1.3×10^{13} cm^{-2}. Meanwhile, mobility decreases from about 2500 cm^2/Vs to 1000 cm^2/Vs, which is still very attractive compared to strained silicon films. The sheet resistance of graphene also decreases, which is an overall result of the competition between the decreased mobility and the increased carrier concentration. Raman spectrum analysis on chlorinated graphene samples treated under different RF bias indicated that the interaction between graphene and chlorine underwent three different scenarios under different RF bias conditions: van der Waals bonding, covalent bonding and defects creation. Finally, by tuning the RF bias and treatment time, we can control the C/Cl ratio effectively.

3:18PM C7.00003 Theory of nanoscale friction on chemically modified graphene , JAE-HYEON KO, YONG-HYUN KIM, Graduate School of Nanoscience and Technology, KAIST — Recently, it is known from FFM experiments that friction force on graphene is significantly increased by chemical modification such as hydrogenation, oxidization, and fluorination, whereas adhesion properties are altered marginally [1]. A novel nanotribological theory on two-dimensional materials is proposed on the basis of experimental results and first-principles density-functional theory (DFT) calculations. The proposed theory indicates that the total lateral stiffness that is the proportional constant of friction force is mostly associated with the out-of-plane bending stiffness of two-dimensional materials. This contrasts to the case of three-dimensional materials, in which the shear strength of materials determines nanoscale friction. We will discuss details of DFT calculations and how to generalize the current theory to three dimensional materials. [1] S. Kwon, J.-H. Ko, K.-J. Jeon, Y.-H. Kim and J. Y. Park, Nano Lett., dx.doi.org/10.1021/nl204019k (2012).

3:30PM C7.00004 Watering Graphene for Devices and Electricity , WANLIN GUO, JUN YIN, XUEMEI LI, ZHUHUA ZHANG, Nanjing University of Aeronautics and Astronautics — Graphene bring us into a fantastic two-dimensional (2D) age of nanotechnology, which can be fabricated and applied at wafer scale, visible at single layer but showing exceptional properties distinguished from its bulk form graphite, linking the properties of atomic layers with the engineering scale of our mankind. We shown that flow-induced-voltage in graphene can be 20 folds higher than in graphite, not only due to the giant Seebeck coefficient of single layer graphene, but also the exceptional interlayer interaction in few layer graphene. Extremely excitingly, water flow over graphene can generate electricity through unexpected interaction of the ions in the water with the graphene. We also find extraordinary mechanical-electric-magnetic coupling effects in graphene and BN systems. Such extraordinary multifield coupling effects in graphene and functional nanosystems open up new vistas in nanotechnology for efficient energy conversion, self-powering flexible devices and novel functional systems.

3:42PM C7.00005 High efficiency graphene solar cell by chemical doping[1] , XIAOCHANG MIAO, SEFAATTIN TONGAY[2], MAUREEN K. PETTTERSON, KARA BERKE, ANDREW G. RINZLER, Department of Physics, University of Florida, Gainesville, Florida 32611, United States, BILL R. APPLETON, Nanoscience Institute for Medical and Engineering Technologies, University of Florida, Gainesville, Florida 32611, United States, ARTHUR F. HEBARD, Department of Physics, University of Florida, Gainesville, Florida 32611, United States — We demonstrate single layer graphene/n-Si Schottky junction solar cells that under AM1.5 illumination exhibit a power conversion efficiency (PCE) of 8.6%. This performance, achieved by doping the graphene with bis(trifluoromethanesulfonyl)amide (TFSA), exceeds the native (undoped) device performance by a factor of 4.5 and is the highest PCE reported for graphene-based solar cells to date. Current–voltage, capacitance–voltage, and external quantum efficiency measurements show the enhancement to be due to the doping-induced shift in the graphene chemical potential that increases the graphene carrier density (decreasing the cell series resistance) and increases the cell's built-in potential (increasing the open circuit voltage) both of which improve the solar cell fill factor.

3:54PM C7.00006 Novel highly conductive graphene-based materials , MONICA CRACIUN, IVAN KHRAPACH, THOMAS BOINTON, FREDDIE WITHERS, DMITRY POLYUSHKIN, WILLIAM BARNES, SAVERIO RUSSO, University of Exeter — The development of future flexible and transparent electronics relies on novel materials, which are mechanically flexible, lightweight and low-cost, in addition to being electrically conductive and optically transparent. Currently, tin doped indium oxide (ITO) is the most wide spread transparent conductor in consumer electronics. The mechanical rigidity of this material limits its use for future flexible electronic applications. We report novel graphene-based transparent conductors obtained by intercalating few-layer graphene (FLG) with ferric chloride (FeCl3). Through a combined study of electrical transport and optical transmission measurements we demonstrate that FeCl3 enhances the electrical conductivity of FLG by two orders of magnitude while leaving these materials highly transparent [1]. We find that the optical transmittance in the visible range of FeCl3-FLG is typically between 88% and 84%, whereas the resistivity is as low as 8.8 Ω. These parameters outperform the best values found in ITO (i.e. resistivity of 10 Ω at an optical transmittance of 85%), making therefore FeCl3-FLG the best candidate for flexible and transparent electronics.

4:06PM C7.00007 Catalytic activity of transition metal-N_4 moieties in graphene toward the oxygen reduction reaction: A DFT study[1] , WALTER ORELLANA, Universidad Andres Bello — The search for non-precious metal cathode catalysts for the oxygen reduction reaction (ORR) that replace platinum in proton exchange membrane fuel cells is one of the main challenges toward the use of hydrogen as clean energy for transportation. Most current works on ORR catalysts focuses on N-coordinated iron in a carbon matrix. Although the nature of the active site is still a mystery, different carbon-supported Fe-N_x active sites have been proposed. In this work, The O_2 dissociation after the interaction with the metal center of M-N_4 moieties in graphene (with M = Mn, Fe, and Co) are addressed by density functional theory calculations. Both, saddle points and minimum energy paths for the ORR in the allowed spin channels have been identified. Our results show that the Mn-N_4 center in graphene exhibits the lowest activation barrier in all spin channel, less than 1 eV, suggesting improved ORR activity, while for Fe-N_4 and Co-N_4 they range between 1.2 and 1.6 eV. Our calculations suggest that the O_2 dissociation would proceed through different spin channel which would increase the reaction rate, particularly for Mn-O_2 and Fe-O_2 moieties. We also investigate energetically favorable routes to incorporate the M-N_4 centers in graphene.

4:18PM C7.00008 ABSTRACT WITHDRAWN –

4:30PM C7.00009 Simulating DNA sequencing using graphene nanopores: a QM/MM Non-equilibrium Green's function approach , ALEXANDRE ROCHA, Institute for Theoretical Physics, Universidade Estadual Paulista (UNESP), Sao Paulo, Brazil, GUSTAVO TROIANO, MAURÍCIO COUTINHO-NETO, Centro de Ciências Naturais e Humanas, Universidade Federal do ABC, Santo Andre, Brazil, RALPH SCHEICHER, Uppsala University, Uppsala, Sweden — Graphene is both the thinnest possible membrane and presents exceptional electronic transport properties. This combination could pave the way for applications in devices where high selectivity single molecule detection is required, for example for sequencing DNA. In this work we will present theoretical electronic transport calculations of a possible DNA sequencing device based on graphene nanopores. We consider both single and double layer graphene. The simulations were performed using a QM/MM method which allows us to treat the graphene sheet containing the nanopore and a segment of DNA within the pore via ab initio density functional theory (QM) whereas the effects of the water molecules, the counter-ions and the remainder of the DNA strand are taken into consideration using a classical potential (MM), in such a way that thousands of atoms can be taken into consideration. The arrangement is allowed to evolve in order to sample the configuration space of different basis, and the electronic transport properties along graphene - from a sample of the frames - are subsequently calculated using non-equilibrium Green's functions taking into consideration the solvent effects in the simulation. The effects of the solvent, counter ions and of different stacked basis will be discussed.

4:42PM C7.00010 Graphene Nanopores for Single-Molecule DNA Sequencing , AARON KUAN, Harvard School of Engineering and Applied Sciences, DAVID HOOGERHEIDE, Harvard Department of Physics, PING XIE, Oxford Nanopore Technologies, DANIEL BRANTON, Harvard Department of Molecular and Cellular Biology, JENE GOLOVCHENKO, Harvard Department of Physics and Harvard School of Engineering and Applied Sciences — We fabricate a nanopore in a suspended single-layer graphene membrane, which serves as a barrier between two aqueous DNA reservoirs. This nanopore device can detect the electrophoretic passage of single or double stranded DNA through transient ionic current blockades caused by DNA obstruction of the pore. Furthermore, a graphene pore, which has atomic thickness, should allow discrimination of different DNA base pairs by ionic current measurements alone. This base discrimination can become the basis of a single-molecule, ultrafast DNA sequencing scheme. We demonstrate the fabrication and evaluate the performance of these graphene nanopore devices.

4:54PM C7.00011 Scalable Arrays of DNA-decorated Graphene Chemical Vapor Sensors , NICHOLAS KYBERT, GANG HEE HAN, MITCHELL LERNER, A.T. CHARLIE JOHNSON, University of Pennsylvania — Chemical vapor sensors based on biomolecular functionalization of graphene field effect transistor arrays are demonstrated. Novel photolithographic methods were developed to fabricate high quality transistors from CVD-grown graphene. Atomic Force Microscopy was used to verify that the graphene surface remained uncontaminated and was thus suitable for controlled chemical functionalization. Single-stranded DNA was chosen as the functionalizing biomolecule due to its affinity to a wide range of target molecules as well as its π-π stacking interaction with graphene, which allowed functionalization with minimal impact on the transistor mobility. The resulting sensor arrays showed analyte and DNA sequence dependent responses down to parts-per-billion level concentrations. By using large arrays of differently functionalized devices, we distinguished chemically similar analytes and determined electronic signatures indicative of their presence.

5:06PM C7.00012 Graphene Nanopres for DNA Fingerprinting[1] , TOWFIQ AHMED, Los Alamos National Laboratory, ALEXANDER V. BALATSKY, Los Alamos National Laboratory and Nordic Institute of Theoretical Physics (Nordita), J.T. HARALDSEN, Los Alamos National Laboratory, IVAN K. SCHULLER, M. DI VENTRA, University of California, San Diego, K.T. WIKFELDT, Nordic Institute of Theoretical Physics (Nordita) — The recent progress in nanopore experiments with transverse current is important for the development of fast, accurate and cheap fingerprinting techniques for single nucleotide. Despite its enormous potential for the next generation DNA sequencing technology, the presence of large noise in the temporal spectrum of transverse current remains a big challenge for getting highly accurate interpretation of data. In this paper we present our *abinitio* calculations, and propose graphene based device for DNA fingerprinting. We calculate transmission current through graphene for each DNA base (A,C,G,T). As shown in our work, a proper time-series analysis of a signal provides a higher quality information in identifying single bio-molecule is translocating through the nanopores.

5:18PM C7.00013 Electrochemistry of Graphene Edge Embedded Nanopores , SHOUVIK BANERJEE, JIWOOK SHIM, JOSE RIVERA, XIAOZHONG JIN, DAVID ESTRADA, VITA SOLOVYEVA, XIUQUE YOU, JAMES PAK, ERIC POP, NARAYANA ALURU, RASHID BASHIR, University of Illinois at Urbana Champaign — We demonstrate a stacked graphene- Al_2O_3 dielectric nanopore architecture to investigate electrochemical activity at graphene edges. It has proven to be difficult to isolate electrochemical activity at the graphene edges from those at the basal planes [1]. We use 24 nm of Al_2O_3 to isolate the graphene basal planes from an ionic fluid environment. Nanopores ranging from 5 to 20 nm are formed by an electron beam sculpting process to expose graphene edges. Electrochemical measurements at isolated graphene edges show current densities as high as 1.2×10^4 A/cm^2, 300x greater than those reported for carbon nanotubes [2]. Additionally, we modulate nanopore conductance by tuning the graphene edge electrochemical current as a function of the applied bias on the embedded graphene electrode. Our results indicate that electrochemical devices based on graphene nanopores have promising applications as sensitive chemical and biological sensors, energy storage devices, and DNA sequencing.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C8 DMP: Complex Structured Materials: Transport and Optical Characterization of Dichalcogenides 307 - Nuh Gedik, Massachusetts Institute of Technology

2:30PM C8.00001 Transport Measurements of Multi-terminal MoS2 Devices , Y. YANG, H.O.H. CHURCHILL, B.W.H. BAUGHER, P. JARILLO-HERRERO, Massachusetts Institute of Technology — We report progress on the fabrication and measurement of multi-terminal devices based on few-layer MoS2. By using different contact metal recipes, we describe efforts to significantly decrease contact resistance and gain access to the intrinsic transport properties of MoS2. We measured four-terminal resistance of monolayer, bilayer, and trilayer MoS2 with Ohmic contacts to obtain the intrinsic field-effect mobility of these materials on SiO2 substrates at temperatures down to 4 K. We also probed Hall transport of MoS2 and extracted the temperature dependence of its Hall mobility.

2:42PM C8.00002 High mobility ambipolar MoS_2 field-effect transistors , WENZHONG BAO, XINGHAN CAI, DO HUN KIM, MICHAEL FUHRER, University of Maryland, CENTER FOR NANOPHYSICS AND ADVANCED MATERIALS, UNIVERSITY OF MARYLAND TEAM — Unlike graphene, single and multilayer MoS2 have a 1-1.8eV band gap, which makes MoS2 an promising candidate for future semiconducting industry. However many groups have observed poor charge carrier mobility for thin MoS_2 crystals deposited on silicon dioxide substrates. Here we report on MoS_2 field effect transistors on SiO_2 and on polymethyl methacrylate (PMMA) dielectric. We measure the conductivity in a four-probe configuration as a funcation of carrier density controlled by the back gate electrode. For multilayer MoS_2 on SiO_2, the mobility is on order 10-60 cm^2/Vs, and independent of thickness (5-80 nm), and most devices exhibit unipolar n-type behavior. In contrast, multilayer MoS_2 on PMMA shows mobility increasing with thickness, up to 500cm^2/Vs (electrons) and 400 cm^2/Vs (holes) at thickness $\sim$50 nm. We observe activated temperature dependence of the resistance consistent with optical phonon scattering-limited resistance in the highest mobility devices. The dependence of the mobility on thickness for thicknesses up to 70 nm is unexpected, and points to a long-range dielectric effect of the bulk MoS_2 in increasing mobility.

2:54PM C8.00003 The effect of the dielectric environment on electrical and optical properties of monolayer molybdenum disulfide , DHIRAJ PRASAI, ALEX WYNN, A.K.M. NEWAZ, KIRILL BOLOTIN, Department of Physics and Astronomy, Vanderbilt University — Monolayer molybdenum disulfide (MoS_2) is a two-dimensional atomic crystal characterized by a direct band gap, strong electron-electron and spin-orbit interactions. Electron transport in currently available monolayer MoS_2 devices is dominated by strong Coulomb scattering limiting carrier mobility to $<$ 200 cm^2/Vs. Here, we explore possible routes towards increasing carrier mobility in MoS_2. First, we investigate suspended ($\sim$200nm above Si/SiO_2) monolayer MoS_2 devices by combining electron beam lithography and an isotropic sacrificial etching of the underlying substrate. Second, we explore the mobility of MoS_2 devices fabricated on highly uniform hexagonal boron nitride (h-BN) crystals as a substrate material. Initial results indicate an order of magnitude increase in the electrical mobility using both approaches. Finally, we study MoS_2 devices embedded in a dielectric material with high dielectric constant and explore the interrelation between carrier mobility and dielectric constant.

3:06PM C8.00004 Phonon Softening and Bandgap Engineering in Strained Monolayer MoS_2[1] , HIRAM CONLEY, KIRILL BOLOTIN, Department of Physics and Astronomy, Vanderbilt University — By straining monolayer MoS_2 with a 4 point bending apparatus, both phonon softening and a shrinking band gap were observed. Raman spectrum demonstrates phonon softening for both bi and single layer MoS_2 flakes, with a breaking of the E^1_{2g} degeneracy at large strain. Photoluminescence data shows that the band gap of single layer MoS_2 decreases by 50 meV per % strain. The direct band gap of bilayer MoS_2 decreases by the same rate as for monolayer MoS_2 while the indirect band gap of bilayer MoS_2 decrease by 120 meV % strain. This work clearly demonstrates that MoS_2's band gap and phonons are tunable by strain engineering suggesting a possibility of devices with mechanically tunable optical and electrical properties.

[1]NSF CAREER grant DMR-1056859

3:18PM C8.00005 Electrical Control of Optical Properties of a Two Dimensional Material, Monolayer Molybdenum Disulfide (MoS_2) , A.K.M. NEWAZ, D. PRASAI, J.I. ZIEGLER, D. CAUDEL, Vanderbilt University, S. ROBINSON, Belmont University, R.F. HAGLUND, K.I. BOLOTIN, Vanderbilt University — Materials with electrically controllable optical properties are long sought for uses in diverse applications ranging from electro-optical modulators to display screens. Here we demonstrate electrical control of photoluminescence quantum yield and absorption coefficient in the visible range for a different two-dimensional crystal, monolayer molybdenum disulfide (MoS_2). We investigate electrical gating of photoluminescence and optical absorption in monolayer MoS_2 configured in field effect transistor geometry. We observe an hundredfold increase in photoluminescence intensity and an increase in absorption at ~ 660 nm in these devices when an external gate voltage is decreased from +50 V to -50 V, while the photoluminescence wavelength remains nearly constant. In contrast, in bilayer MoS_2 devices we observe almost no changes in photoluminescence with gate voltage. We propose that the differing responses of the monolayer and bilayer devices are related to the interaction of the excitons in MoS_2 with charge carriers.

3:30PM C8.00006 Excited-state interactions in monolayer MoS_2/graphene heterostructures , CYRIELLE ROQUELET, Department of Physics and Chemistry, Columbia University, New York 10027, HEATHER HILL, Department of Physics, Columbia University, AREND VAN DER ZANDE, FAN ZHANG, JAMES HONE, Department of Mechanical Engineering, Columbia University, LOUIS E. BRUS, Department of Chemistry, Columbia University, TONY F. HEINZ, Department of Physics and Electrical Engineering, Columbia University — Recent progress in the formation of atomically thin 2-dimensional crystals by mechanical exfoliation and other synthetic techniques has led to the availability and study of various 2D materials other than graphene. Among them, molybdenum disulfide (MoS_2) has attracted particular attention. Although an indirect-gap material in the bulk, MoS_2 exhibits a direct gap in its monolayer form. Correspondingly, the material exhibits strong photoluminescence (PL), very sensitive to the environment. With the development of transfer techniques, it is now possible to create stacks of differing atomically thin materials. In this paper we apply this to investigate the influence of adjacent graphene layers on the PL of MoS_2 monolayers. Comparing the PL from MoS_2 on graphene with reference samples, we find that graphene induces strong quenching. Raman measurements of the graphene do not indicate the presence of any significant static charge transfer between layers. This suggests that the graphene layer provides efficient relaxation channels for the photoexcited MoS_2, rather than modifying its intrinsic properties. In this context, we discuss the relative contributions to PL quenching arising from excited-state charge and energy transfer processes.

3:42PM C8.00007 Ultrafast laser spectroscopy of exciton dynamics in CVD-grown monolayer MoS_2 , EDBERT JARVIS SIE, YIHUA WANG, YI-HSIEN LEE, JING KONG, NUH GEDIK, MIT — Recently, much effort has been devoted to the spin-valley interplay in exfoliated monolayer MoS_2, yet the many-body interactions in this material are largely unexplored. In fact, monolayer MoS_2 offers a special platform in the study of many-body effects owing to its 2D nature with a large band gap and a giant exciton binding energy. Here, we use ultrafast laser spectroscopy to study the exciton dynamics of CVD-grown monolayer MoS_2. We observed a strongly non-linear fluence dependent behavior which indicates presence of many-body interactions in this material.

3:54PM C8.00008 MoS_2 Field Effect Transistors with different polarity: study of electrode work functions[1] , ISHA DUBE, ANTHONY K. BOYD, Georgetown University, MARCIO FONTANA, Federal University of Bahia, Salvador, IGOR GAYDUCHENKO, GEORGY FEDOROV, National Research Centre Kurchatov Institute, Moscow, Russia., AMY LIU, MAKARAND PARANJAPE, PAOLA BARBARA, Georgetown University — The transfer characteristics of Molybdenum disulfide (MoS_2) field effect transistors (FETs) depend on the Schottky barrier formed between the metal electrode and the semiconducting MoS_2. We obtained p-type behavior for Pd-contacted MoS_2 FETs and n-type with both Au and Nb [1] contacts. We study the work function of these electrode metals to understand their effect on the Schottky barrier and therefore the polarity of the MoS_2 FETs. The work function of the above metals is measured using a non-contact Kelvin Probe technique under different ambient conditions. We will discuss the observed n-type and p-type behavior of MoS_2 FETs in relation to the measured metal work functions.

4:06PM C8.00009 Electronic Transport through Grain Boundaries in Monolayer Molybdenum Disulfide Grown by Chemical Vapor Deposition , DANIEL CHENET, AREND VAN DER ZANDE, Columbia University, PINSHANE HUANG, Cornell University, YUMENG YOU, TIMOTHY BERKELBACH, Columbia University, GWAN-HYOUNG LEE, Samsung-SKKU Graphene Center (SSGC), Suwon, Korea, DAVID REICHMAN, Columbia University, DAVID MULLER, Cornell University, TONY HEINZ, JAMES HONE, Columbia University — Monolayer molybdenum disulfide is a new direct bandgap semiconductor that has recently received significant attention for its potential utility in two-dimensional electronics. Recent advances in the large-area synthesis of this material by chemical vapor deposition are accelerating the device concept to realization process. However, little is currently known about the effect of growth defects on electronic transport in this material. Here, we have optimized the synthesis process to grow large single crystals up to 120 μm in size with electrical and optical properties comparable or superior to that of exfoliated samples. When these single crystals grow together to form large continuous sheets, the inevitable consequence is the formation of grain boundaries that should have different electrical properties than the bulk. With our ability to rapidly identify well-faceted single crystals and the boundaries between them by optical microscopy, we fabricate field effect transistors to measure the effects of individual grain boundaries on channel conductivity and mobility.

4:18PM C8.00010 Electron-hole transport and photovoltaic effect in gated MoS_2 Schottky junctions[1] , ANTHONY BOYD, Georgetown University, MARCIO FONTANA, Georgetown University, Federal University of Bahia, TRISTAN DEPPE, MOHAMED RINZAN, AMY LIU, MAKARAND PARANJAPE, PAOLA BARBARA, Georgetown University — Atomically thin molybdenum disulfide has emerged as an attractive material for novel nanoscale optoelectronic devices due to its reduced dimensionality and large direct bandgap. Since optoelectronic devices require electron-hole generation/recombination, it is important to be able to fabricate ambipolar transistors to investigate charge transport both in the conduction band and in the valence band. Although n-type transistor operation for single-layer and few-layer MoS_2 with gold source and drain contacts was recently demonstrated..., transport in the valence band has been elusive for solid-state devices. Here we show that a multi-layer MoS_2 channel can be hole-doped by palladium contacts, yielding MoS_2 p-type transistors [1]. When two different materials are used for the source and drain contacts, for example hole-doping Pd and electron-doping Au, the Schottky junctions formed at the MoS_2 contacts produce a clear photovoltaic effect [1].

[1]Work Funded by NSF, DMR 1008242.

4:30PM C8.00011 Electrical control of truly two-dimensional neutral and charged excitons in monolayer $MoSe_2$[1] , JASON ROSS, SANFENG WU, University of Washington, HONGYI YU, University of Hong Kong, NIRMAL GHIMIRE, University of Tennessee, AARON JONES, GRANT AIVAZIAN, University of Washington, JIAQIANG YAN, Oak Ridge National Lab, DAVID MANDRUS, University of Tennessee, DI XIAO, Carnegie Mellon University, DI XIAO, University of Hong Kong, XIAODONG XU, University of Washington — Monolayer transition metal dichalcogenides (TMDs) have emerged as ideal 2D semiconductors with valley and spin polarized excitations expected to enable true valleytronics. Here we investigate $MoSe_2$, a TMD which has yet to be characterized in the monolayer limit. Specifically, we examine excitons and trions (their singly charged counterparts) in the ultimate 2D limit. Utilizing high quality exfoliated $MoSe_2$ monolayers, we report the observation and electrostatic tunability of positively charged (X+), neutral (Xo), and negatively charged (X-) excitons via photoluminescence in FETs. The trion charging energy is large (30 meV), enhanced by strong confinement and heavy effective masses, while the linewidth is narrow (5 meV) at temperatures below 55 K. This is greater spectral contrast than in any known quasi-2D system. Further, the charging energies for X+ and X- to are nearly identical implying the same effective mass for electrons and holes, which supports their recent description as massive Dirac fermions. This work demonstrates that monolayer $MoSe_2$ is an ultimate 2D semiconductor opening the door for the investigation of truly 2D exciton physics while laying the ground work necessary to begin valley-spin polarization studies.

4:42PM C8.00012 The influence of composition and mechanical strain on the optoelectronic properties of transition-metal dichalcogenide monolayers , ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst — Single and few-layer transition-metal dichalcogenides (TMDs) are of significant current interest for nanoscale optoelectronic applications. While these materials have been well characterized in their bulk form, a comprehensive understanding of their properties at the nanoscale is still emerging. We present studies of the quasiparticle band structures and optical properties of MoS_2, $MoSe_2$, $MoTe_2$, WS_2, and WSe_2 monolayers using the GW approximation in conjunction with the Bethe-Salpeter equation (BSE). The inclusion of two-particle excitations in the BSE approach reveals the presence of two strongly bound excitons (A and B) below the quasiparticle absorption onset arising from vertical transitions between a spin-orbit-split valence band and the conduction band. The transition energies for monolayer MoS_2, in particular, are shown to be in excellent agreement with available experiments. Excitation energies for the remaining monolayers are predicted to lie in the range of 1–2 eV. Systematic trends are identified for band gaps, transition energies, and exciton binding energies within as well as across the Mo and W families of dichalcogenides. Finally, we study the influence of homogeneous strains on the optoelectronic properties of TMD monolayers and demonstrate the potential for facile tuning of electronic and optical band gaps. Overall, the results suggest that quantum confinement of carriers within monolayers can be exploited in conjunction with chemical composition and mechanical strains to widely tune the optoelectronic properties of TMDs at the nanoscale.

4:54PM C8.00013 Photoluminescence mapping of grain boundaries in CVD-grown MoS_2 monolayers , YUMENG YOU, AREND VAN DER ZANDE, DANIEL CHENET, Columbia University, New York, NY, PINSHANE HUANG, Cornell University, Ithaca, NY, JAMES HONE, Columbia University, New York, NY, DAVID MULLER, Cornell University, Ithaca, NY, TONY HEINZ, Columbia University, New York, NY — Monolayer MoS_2 is an atomically thin 2-D material with a direct energy gap. Recently, rapid progress has been made in the growth of this material by chemical vapor deposition (CVD). Here we apply photoluminescence (PL) mapping to study monolayer MoS_2 samples prepared by CVD. For appropriate growth conditions, MoS_2 monolayers can be grown that exhibit well-defined boundaries between different crystal domains. Using electron microscopy, we have identified boundaries between crystals of different orientation and between mirror-twin crystals. PL mapping has been found to permit the ready identification of both of these boundaries through shifts in the strength and energy of the emission peaks. This sensitivity renders PL imaging a convenient tool for the identification of grain boundaries that remain hidden in conventional optical microscopy. The strong structural modification of material at a grain boundary extends for only around 1 nm. Thus only slight variation in the PL might be anticipated, given the excitation laser spot size of around 500 nm. We will discuss the possible physical origins of the strong contrast observed in the PL maps, including the role of exciton diffusion to the grain boundaries.

5:06PM C8.00014 Metal Contacts on Semiconducting Two-Dimension Crystals , HAN LIU, ADAM NEAL, YUCHEN DU, PEIDE YE, School of Electrical and Computer Engineering, Purdue University — Semiconducting 2-D crystals, such as MoS_2, WSe_2, are viewed as promising candidates for electronic applications for their high carrier mobility, thermal stability, compatibility to CMOS process, and superior immunity to short channel effects. However, with the difficulty in ion implantation, the metal contacts on 2-D crystals are yet with large contact resistance, thus eliminates further device performance. We study different metal contacts from low work function to high work function metals on MoS_2 and WSe_2 crystals with various thicknesses and discuss the Fermi level pinning at the metal/semiconductor interface. Effective Schottky Barrier Heights (SBHs) are also measured. Molecular doping and dual-side contacts metals are performed as two tentative solutions to reduce the effective SBHs, and high-performance of field effect transistors are achieved by reduced contact resistance.

5:18PM C8.00015 Electronic properties of bilayer mixtures of WS2 and MoS2 with different stackings[1] , HUMBERTO TERRONES, ANA LAURA ELIAS, NESTOR PEREA-LOPEZ, The Pennsylvania State University, HUMBERTO R. GUTIERREZ, University of Louisville, AYSE BERKDEMIR, ANDRES CASTRO-BELTRAN, RUITAO LV, The Pennsylvania State University, FLORENTINO LOPEZ-URIAS, The Pennsylvania State University, IPICYT, TAKUYA HAYASHI, YOONG AHM KIM, MORINOBU ENDO, Shinshu University, MAURICIO TERRONES, The Pennsylvania State University — Besides graphene and hexagonal boron nitride, transition metal chalcogenides (TMC) such as MoS2, WS2, NbS2 and WSe2 also exhibit a layered structure in which the layers weakly interact via Van der Waals forces, and for this reason these materials exhibit excellent lubrication properties. For TMC, the layers are formed by the transition metal atom sandwiched by the sulfur atoms. MoS2 and WS2 in bulk are indirect band gap semiconducting materials. However, an isolated sheet of MoS2 or WS2 becomes a direct gap semiconductor. This particular behavior makes them very attractive in terms of optical properties such as spin polarization, in which the lack of center of inversion of one layer plays a crucial role. Therefore, it is important to study the properties of different configurations of WS2 and MoS2 mixtures bi-layer TMC systems with different stackings. First principles calculations are carried out to study how the indirect and the direct gaps behave, thus shedding light in a new type of bi-layered material.

Session C9 DCOMP: Invited Session: Recent Developments in Density Functional Theory I 308

- Timo Thonhauser, Wake Forest University

2:30PM C9.00001 Aneesur Rahman Prize for Computational Physics Lecture: Addressing Dirac's Challenge[1] , JAMES CHELIKOWSKY, University of Texas at Austin — After the invention of quantum mechanics, P. A. M. Dirac made the following observation: "The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the exact application of these laws leads to equations much too complicated to be soluble. It therefore becomes desirable that *approximate practical methods* of applying quantum mechanics should be developed, which can lead to an explanation of the main features of complex atomic systems..." The creation of "approximate practical methods" in response to Dirac's challenge has included the one electron picture, density functional theory and the pseudopotential concept. The combination of such methods in conjunction with contemporary computational platforms and new algorithms offer the possibility of predicting properties of materials solely from knowledge of the atomic species present. I will give an overview of progress in this field with an emphasis on materials at the nanoscale.

[1]Support from the Department of Energy and the National Science Foundation is acknowledged.

3:06PM C9.00002 Recent Progress in Linear Scaling DFT , DAVID BOWLER, University College London — Linear scaling or O(N) electronic structure codes have been under development for around fifteen years. After an initial explosion of interest, the practical difficulties of implementation and efficiency have led to a slow down in development and applications. In this talk I will present details of recent developments in the massively parallel CONQUEST linear scaling DFT code, and make some comments on the linear scaling field in general. The CONQUEST code is one of the leading O(N) codes, and has demonstrated not only excellent scaling to over two million atoms and many thousands of cores but also practical applications to nanostructures on semiconductor surfaces, and recently to biological systems. I will describe the details of the CONQUEST code, including recent developments in basis functions and parallelisation. I will also discuss recent improvements including constrained DFT, exact exchange and TDDFT, all of which have been implemented with linear scaling.

D. R. Bowler and T. Miyazaki, Rep. Prog. Phys. **75** 036503 (2012).

3:42PM C9.00003 Electron response in van der Waals density functionals , PER HYLDGAARD, Microtechnology and Nanoscience - MC2, Chalmers University of Technology, 41296 Gothenburg — There is significant interest in density functional theory (DFT) of dispersive or van der Waals (vdW) interactions and in DFT studies of sparse systems where vdW forces contribute to the cohesion and behavior. The Rutgers-Chalmers van der Waals density functional (vdW-DF) method [PRL **92**, 246401 (2004); PRB **76**, 125112 (2007)] is a nonempirical approach to calculate vdW bonding and for DFT characterizations of sparse matter. The vdW-DF framework is defined by a single exchange-correlation density functional that rests on a plasmon-type description for both semilocal components and for a parameter-free evaluation of nonlocal correlation. My talk summarizes a set of vdW-DF studies that seeks to map and analyze details in the vdW-DF electron-response nature. The purpose is in part to extract consequences that can facilitate an experiment-theory comparison that goes beyond binding geometries and energies. The aim is also to seek implications that can help develop the vdW-DF framework. I present an analysis of the relative importance of morphology, screening (image-plane formation), and collective effects in the vdW-DF description of molecular systems. In addition, I compare vdW-DF results with Cu(111) experiments that tests the electron-response behavior in terms of adsorption-induced band shifts, the form of the overall light-molecule physisorption potential, and the corrugation in the kinetic-energy repulsion of molecules at surfaces. Overall, the vdW-DF studies suggest the importance of benchmarking vdW methods across different length scales and by exploring the variation that arise when related structures have a different balance between exchange repulsion and vdW attraction.

4:18PM C9.00004 Time-Resolved Dynamics in Time-Dependent Density Functional Theory: Significance of Non-locality in Space and Time[1] , NEEPA MAITRA, Hunter College and the Graduate Center of the City University of New York — The usual approximations in Time-Dependent Density Functional Theory (TDDFT) have achieved an unprecedented balance between accuracy and efficiency for calculating excitation spectra and response. We show however that these approximations are less successful for time-resolved dynamics beyond the linear response regime. Step and peak structures develop in the exact exchange-correlation potential that have a density-dependence that is non-local both in time and in space, missed by all approximations in use today. The lack of these structures leads to their incorrect predictions of dynamics, such as faster time-scales, and incomplete charge-transfer. [P. Elliott, J.I. Fuks, A. Rubio, N.T. Maitra arXiv:1211.2012; J. I. Fuks, P. Elliott, A. Rubio, N. T. Maitra, arXiv:1211.2849]

4:54PM C9.00005 Improving Density Functionals with Quantum Harmonic Oscillators , ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG — Density functional theory (DFT) is the most widely used and successful approach for electronic structure calculations. However, one of the pressing challenges for DFT is developing efficient functionals that can accurately capture the omnipresent long-range electron correlations, which determine the structure and stability of many molecules and materials. Here we show that, under certain conditions, the problem of computing the long-range correlation energy of interacting electrons can be mapped to a system of coupled quantum harmonic oscillators (QHOs). The proposed model allows us to synergistically combine concepts from DFT, quantum chemistry, and the widely discussed random-phase approximation for the correlation energy. In the dipole limit, the interaction energy for a system of coupled QHOs can be calculated exactly, thereby leading to an efficient and accurate model for the many-body dispersion energy of complex molecules and materials. The studied examples include intermolecular binding energies, the conformational hierarchy of DNA structures, the geometry and stability of molecular crystals, and supramolecular host–guest complexes (A. Tkatchenko, R. A. DiStasio Jr., R. Car, M. Scheffler, Phys. Rev. Lett. 108, 236402 (2012); R. A. DiStasio Jr., A. von Lilienfeld, A. Tkatchenko, PNAS 109, 14791 (2012); A. Tkatchenko, D. Alfe, K. S. Kim, J. Chem. Theory and Comp. (2012), doi: 10.1021/ct300711r; A. Tkatchenko, A. Ambrosetti, R. A. DiStasio Jr., arXiv:1210.8343v1).

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C10 DCMP GMAG: Invited Session: Stabilization and Dynamics of Magnetic Skyrmions

309 - N.P. Onn, Princeton University

2:30PM C10.00001 Emergent Electrodynamics of Skyrmions in Chiral Magnets , CHRISTIAN PFLEIDERER, Technische Universitaet Muenchen — Skyrmions are particle-like states of continuous fields named after the English particle physicist Tony Skyrme. Their existence has long been considered in nuclear matter, quantum Hall systems, liquid crystals, superfluid ^{3}He and ultracold atoms. As their defining property they support a topological winding number of 1. In magnetic materials spin configurations with a non-vanishing topological winding number, driven by the interplay of magnetic anisotropies, dipolar interactions and geometrical frustration, have been known for a long time. This is contrasted by the recent discovery of skyrmion lattices in chiral magnets, i.e., long-range magnetic order in which each magnetic unit cell contains a skyrmion and thus a non-zero winding number. As a practical consequence, the non-zero topological winding number implies that the conduction electrons in the presence of a skyrmion experience changes of Berry phase, that correspond precisely to one quantum of emergent magnetic flux. In transport measurements this leads directly to a topological Hall signal. Moreover, tiny electric current densities are already sufficient to generate a motion of the skyrmions first observed indirectly in neutron scattering. Since each skyrmion supports one quantum of emergent magnetic flux the motion of the skyrmions induces an emergent electric field consistent with Faradays law of induction that may also be observed experimentally. The excellent theoretical description of the skyrmion lattices observed so far in metals, doped semiconductors and insulators suggests that they represent a rather universal phenomenon to be expected in a wide range of systems supporting chiral spin interactions. Taken together with the first insights into their emergent electrodynamics, skyrmion lattices in chiral magnets develop into a new area of condensed matter magnetism offering insights relevant for applications.

3:06PM C10.00002 Extended skyrmion phase in epitaxial FeGe(111) thin films , SUNXIANG HUANG, Johns Hopkins University — Exotic magnetic skyrmions with a new type of topological spin texture have recently been observed in cubic B20 magnets such as MnSi and FeGe [1]. Skyrmions, with a double-twist spin texture carrying a topological charge and a Berry phase in real space, can form long-range ordered structure or behave as solitons [2]. These magnetic skyrmions not only provide a novel route to study the topological nature of magnetic defects but also exhibit spectacular static and dynamic properties such as translational and rotational motion driven by electric current with ultra-low current density. Unfortunately, the skyrmion phase in bulk crystals exists only in a very small region of a few K and a narrow magnetic field range in the phase space. However, theories and some experiments suggest that the skyrmion phase may be greatly expanded in thin films. In this work, we describe the realization of B20 FeGe thin films with greatly expanded skyrmion phase [3]. FeGe has the highest Curie temperature $T_C \approx 280$ K among the B20 skyrmion materials, but FeGe crystals rarely exceed 1 mm. We have succeeded in the epitaxial growth of FeGe(111) thin films on Si(111). We show that the skyrmion states, as revealed by the topological Hall effect and the small angle neutron scattering (SANS), are stabilized in a dramatically larger region in phase space in FeGe films, including the entire temperature range up to T_C, and in a large field range. Furthermore, the properties of the skyrmion phase can be controlled and manipulated by the film thickness. Other aspects of the skyrmion states as revealed by transport and neutron measurements will also be discussed. This work is in collaboration with C. L. Chien and C. Broholm at JHU and L. Debeer-Schmitt and K. Littrell at ORNL.

3:42PM C10.00003 Realization and dynamics of 2D magnetic skyrmions[1] , XIUZHEN YU, The Institute of Physical and Chemical Research — The skyrmion, a vortex-like topological spin texture, can be excited by the external magnetic field (B) in helimagnets [1-6]. The skyrmion lattice was recently confirmed by small-angle scattering neutron observations in a helimagnet MnSi [1] where the skyrmion phase was observed in a narrow window of (T, B)-plane. In contrast with unstable skyrmions in the bulk, by using Lorentz transmission electron microscopy (TEM), we have realized two-dimensional (2D) skyrmion crystal (SkX) over a wider region in (T, B)-plane for thin helimagnets [2-6] which thicknesses are smaller than their helical periods. Furthermore, we have realized the near RT ($\sim$280 K) formation of SkX in a helimagnet FeGe [3]. We have clarified the stability condition for the SkX, i.e. the magnetic-dimension (from 2D to 3D) variation of SkX phase diagram in (T, B)-plane. The skyrmion acts as a magnetic flux owing to its curved spin texture. When an electric current flowing through the skyrmion exceeds a critical current density for depinning, the skyrmion can accept the spin transfer torque to be driven along the current direction. Combining electrical and magnetic control in a microdevice composed of a FeGe thin plate, we have realized nanometric skyrmions under a weak magnetic field (150 mT) and manipulated them with an ultra-low current density ($\sim 5 \times 10^4 \mathrm{A/m^2}$) [6], several orders lower than that required to drive domain walls in conventional ferromagnets [7]. This work has been done in collaboration with Prof. Y. Tokura, Prof. N. Nagaosa, Dr. Y. Matsui, Prof. Y. Onose, Mr. N. Kanazawa, Dr. K. Kimoto, Dr. T. Hara, Dr. T. Nagai, and Ms. W-Z. Zhang.

4:18PM C10.00004 Beller Lectureship: Dynamics of skyrmions under electric current[1] , NAOTO NAGAOSA, University of Tokyo — Current-driven motion of the skyrmions and skyrmion crystal is attracting intense attention because of the very small critical current density, but the microscopic mechanism of their motion is not yet explored. In this talk, I will present a numerical simulation of the Landau-Lifshitz-Gilbert (LLG) equation and an analytic theory, which reveals a remarkably robust and universal current-velocity relation of the skyrmion motion driven by the spin transfer torque unaffected by either impurities or nonadiabatic effect in sharp contrast to the case of domain wall or spin helix. This is due to the peculiar dynamics of skyrmions characterized by inherent absence of the intrinsic pinning and flexible shape-deformation of skyrmions so as to avoid pinning centers. The effect of the constricted geometry will be also discussed. This work has been done in collaboration with J. Iwasaki and M. Mochizuki.

4:54PM C10.00005 Spontaneous atomic-scale magnetic skyrmion lattice in two dimensions , STEFAN HEINZE, Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany — Skyrmions are topologically protected field configurations with particle-like properties that play an important role in various fields of science. They have been predicted to exist also in bulk magnets and in recent experiments it was shown that they can be induced by a magnetic field. A key ingredient for their occurrence is the Dzyaloshinskii-Moriya interaction (DMI) which was found to be strong also for magnetic nanostructures on substrates with large spin-orbit coupling [1]. In these systems the DMI stabilizes spin-spirals with a unique rotational sense propagating along one direction of the surface as observed for ultrathin films [1-3] and atomic chains [4]. Here, we go a step beyond and present an atomic-scale skyrmion lattice as the magnetic ground state of a hexagonal Fe monolayer on Ir(111) [5]. We develop a spin-model based on density functional theory that explains the interplay of Heisenberg exchange, DMI and the four-spin exchange as the microscopic origin of this intriguing magnetic state. Experiments using spin-polarized scanning tunneling microscopy confirm the skyrmion lattice which is incommensurate with the underlying atomic lattice. This work is a collaboration with G. Bihlmayer, S. Blügel, K. von Bergmann, M. Menzel, A. Kubetzka, J. Brede, and R. Wiesendanger.

Session C11 GQI DAMOP: Invited Session: Quantum Communication and Cryptography 310 - Mark Wilde, McGill University and Louisiana State University

2:30PM C11.00001 Limits on classical communication from quantum entropy power inequalities , GRAEME SMITH, IBM Research — Almost all modern communication systems rely on electromagnetic fields as a means of information transmission, and finding the capacities of these systems is a problem of significant practical importance. The Additive White Gaussian Noise (AWGN) channel is often a good approximate description of such systems, and its capacity is given by a simple formula. However, when quantum effects are important, estimating the capacity becomes difficult: a lower bound is known, but a similar upper bound is missing. Here we present strong new upper bounds for the classical capacity of quantum additive noise channels, including quantum analogues of the AWGN channel. Our main technical tool is a quantum entropy power inequality that controls the entropy production as two quantum signals combine at a beam splitter. Its proof involves a new connection between entropy production rates and a quantum Fisher information, and uses a quantum diffusion that smooths arbitrary states towards gaussians.

3:06PM C11.00002 Security of continuous-variable quantum key distribution against general attacks[1] , ANTHONY LEVERRIER, INRIA Rocquencourt — We prove the security of Gaussian continuous-variable quantum key distribution with coherent states against arbitrary attacks in the finite-size regime. In contrast to previously known proofs of principle (based on the de Finetti theorem), our result is applicable in the practically relevant finite-size regime. This is achieved using a novel proof approach, which exploits phase-space symmetries of the protocols as well as the postselection technique introduced by Christandl, Koenig and Renner (*Phys. Rev. Lett.* 102, 020504 (2009)).

3:42PM C11.00003 Fully device-independent quantum key distribution , THOMAS VIDICK, Massachusetts Institute of Technology (MIT) — The laws of quantum mechanics allow unconditionally secure key distribution protocols. Nevertheless, security proofs of traditional quantum key distribution (QKD) protocols rely on a crucial assumption, the trustworthiness of the quantum devices used in the protocol. In device-independent QKD, even this last assumption is relaxed: the devices used in the protocol may have been adversarially prepared, and there is no a priori guarantee that they perform according to specification. Proving security in this setting had been a central open problem in quantum cryptography. We give the first device-independent proof of security of a protocol for quantum key distribution that guarantees the extraction of a linear amount of key even when the devices are subject to a constant rate of noise. Our only assumptions are that the laboratories in which each party holds his or her own device are spatially isolated, and that both devices, as well as the eavesdropper, are bound by the laws of quantum mechanics. All previous proofs of security relied either on the use of many independent pairs of devices, or on the absence of noise.

4:18PM C11.00004 Quantum hacking , VADIM MAKAROV, University of Waterloo — -

4:54PM C11.00005 Complete experimental toolbox for alignment-free quantum communication[1]

, FABIO SCIARRINO, Dipartimento di Fisica, Sapienza Università di Roma — Quantum communication employs the counter-intuitive features of quantum physics for tasks that are impossible in the classical world. It is crucial for testing the foundations of quantum theory and promises to revolutionize information and communication technologies. However, to execute even the simplest quantum transmission, one must establish, and maintain, a shared reference frame. This introduces a considerable overhead in resources, particularly if the parties are in motion or rotating relative to each other. We experimentally show how to circumvent this problem with the transmission of quantum information encoded in rotationally invariant states of single photons. Our approach exploits multiple degrees of freedom of single photons. In particular, the polarization and transverse spatial modes stand out for this purpose. Just as the circular polarization states are eigenstates of the spin angular momentum of light, the helical-wavefront Laguerre-Gaussian modes are eigenmodes of its orbital angular momentum (OAM). We implement photonic qubit invariant under rotation around the optical axis by combining the polarization with OAM properties. By developing a complete toolbox for the efficient encoding and decoding of quantum information in such photonic qubits, we demonstrate the feasibility of alignment-free quantum key-distribution, and perform proof-of-principle demonstrations of alignment-free entanglement distribution and Bell-inequality violation. The core of our toolbox is a liquid crystal device, named "q-plate," that maps polarization-encoded qubits into qubits encoded in hybrid polarization-OAM states of the same photon that are invariant under arbitrary rotations around the propagation direction, and vice versa. The scheme should find applications in fundamental tests of quantum mechanics and satellite-based quantum communication. We will discuss the potential applications of this scheme to real quantum communication network.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C12 DMP: Focus Session: Complex Oxide Interfaces - Polar interfaces I 314 - Mark Rzchowski, University of Wisconsin, Madison

2:30PM C12.00001 Photo-sensitive Transport Properties of the Two-dimensional Electron Gas at $LaAlO_3/SrTiO_3$ Interfaces

, T. HERNANDEZ, SANGWOO RYU, C.W. BARK, C.B. EOM, M.S. RZCHOWSKI, University of Wisconsin-Madison — Photoresistance has been previously well characterized in highly resistive ($> 10^6$ $\Omega/\Box$) $LaAlO_3/SrTiO_3$ heterostructures, showing a decrease in resistance on exposure to light. In some cases insulating heterostructures with $LaAlO_3$ layer below the critical thickness have become conducting on exposure to light. Here we report on the effects of light exposure on much lower sheet resistance ($\sim 10^4$ $\Omega/\Box$) $LaAlO_3/SrTiO_3$ interfaces, which we find to show a non-negligible increase in resistance. This effect is opposite to the behavior of our more resistive samples. We discuss temperature and magnetic field dependence, possible mechanisms for this behavior, and the implications for other transport properties.

2:42PM C12.00002 Ultrafast photoresponse of oxide nanostructures[1]

, LU CHEN, YANJUN MA, MENGCHEN HUANG, University of Pittsburgh, SANGWOO RYU, CHUNG WUNG BARK, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — Photoconductivity has been demonstrated for nanostructures at the interface of $LaAlO_3/SrTiO_3$ and spectral response shows signatures of in-gap states being responsible for photoresponse[2]. However, as a wide bandgap material, $SrTiO_3$ shows large nonlinear optical coefficients. Here we discuss time-resolved measurements for exploring the nonlinearity of photoconductivity in the oxide nanostructures. It is found that a nonresonant $\chi^{(3)}$ process results in the observed tunable localized ultrafast response, as well as optical rectification, which can principally lead to the generation and detection of THz radiation. Due to the nanoscale nature of our device, these results foreshadow the control of THz field at single molecule scales.

2:54PM C12.00003 Real-time characterization of nanostructures written at the $LaAlO_3/SrTiO_3$ interface[1]

, ALEXANDRE GAUTHIER, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Nanostructures can be written on the $LaAlO_3/SrTiO_3$ interface using conductive AFM lithography[2]. These structures can be configured into devices including photodetectors[3] and transistors[4]. Characterization of complex devices requires simultaneous measurements between several pairs of electrodes. We have developed a method to take measurements between all electrodes simultaneously by both measuring and applying a bias at a unique frequency to each electrode. Fourier analysis is then used to separate measured signals by source terminal. This allows us to efficiently characterize multi-terminal devices in real-time, as they are being created. This method will allow for the use of new experimental techniques.

3:06PM C12.00004 Direct Patterning of Oxide Interface with High Mobility 2DEG without Physical Etching

, NIRUPAM BANERJEE, MARK HUIJBEN, GERTJAN KOSTER, GUUS RIJNDERS, University of Twente — Discovery of highly mobile two dimensional electron gas (2DEG) at the atomically engineered interface between two wide band-gap perovskite insulators, SrTiO3 (STO) and LaAlO3 (LAO) has stimulated the research to apply oxide materials in electronic devices such as high mobility electron transistors (HMET). In spite of excellent interfacial transport properties manifested, challenges remained in structuring these heterointerfaces without damaging the STO single crystal. Top-down physical etching process was an unsuitable choice to serve the purpose since it induces substrate conductivity through creation of oxygen vacancies. Here, we will demonstrate development of a novel procedure for fabricating patterned functional interfaces based on epitaxial-lift-off technique. With its help devices incorporating patterned interfaces of LAO-STO was fabricated devoid of any physical etching process performed and temperature dependent magneto transport properties were investigated. The results demonstrated conservation of the high-quality interface properties in the patterned structures enabling future studies of low-dimensional confinement on high mobility interface conductivity as well as interfacial magnetism.

3:18PM C12.00005 Local characterization and charge modification of $LaAlO_3/SrTiO_3$ heterointerface: influence of gas environment , HAERI KIM, DONG-WOOK KIM, Ewha Womans University, SEON YOUNG MOON, SEUNG HYUP BAEK, Korea Institute of Science and Technology, HO WON JANG, Seoul National University — The discovery of high-mobility 2D electron gas (2DEG) at the interface between two band insulators, $LaAlO_3$ and $SrTiO_3$ (LAO/STO) has stimulated researches for both applications and fundamental understanding of the intriguing phenomena. Recent experimental and theoretical studies have elucidated roles of charged surface adsorbates on the modification of the resistance of the LAO/STO system. Thus, manipulation and characterization of the surface charges on the LAO/STO surface can be crucial step for unveiling the mechanism of the peculiar physical phenomena. In this work, we used scanning probe microscopy (SPM) to investigate how the ambient gas, such as H_2/Ar, Ar, and O_2, could influence the work function and resistance of the LAO/STO system. Also, we studied how the SPM tip-induced charge writing affected the surface potential, Vsurf, and resistance of the LAO/STO. Quantitative measurement of the influence of ambient gas and the charge writing on the surface potential led us to develop a model to explain the unique transport properties of the oxide-based 2DEG.

3:30PM C12.00006 Piezoresponse force microscopy imaging of nanostructures created by conductive AFM lithography at oxide heterointerfac[1] , MENGCHEN HUANG, FENG BI, University of Pittsburgh, SANGWOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — Nanoscale control of the metal-insulator transition in 3-unit cell (u.c.) $LaAlO_3/SrTiO_3$ heterostructures using conductive AFM (c-AFM) lithography allows the creation of conductive nanostructures [2]. Piezoelectric effects have recently been observed in planar $LaAlO_3/SrTiO_3$ heterostructures [3], and the piezoresponse differs between the conducting and insulating states of 3-u.c. samples where c-AFM modulates the transition [4]. We have employed piezoresponse force microscopy (PFM) to detect and image the piezoresponse variations of nanostructures created by c-AFM lithography. PFM imaging allows visualization of the nanostructures, expanding capabilities for characterizing and studying individual devices.

3:42PM C12.00007 Parallel conductive-AFM lithography of $LaAlO_3/SrTiO_3$ using 1D multiple-tip array[1] , SHUO LI, MENGCHEN HUANG, FENG BI, University of Pittsburgh, SANGWOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — Nanoscale devices at the $LaAlO_3/SrTiO_3$ interface can be created by metastable charging of the top $LaAlO_3$ surface using a voltage-biased conductive-AFM tip.[2] In order to create scalable nanoelectronic circuits, it will be important to develop a process to allow multiple tips to write nanostructures in parallel. Here we demonstrate a parallel writing scheme using a 1D multiple-tip array. Independent control over the writing process for each tip is achieved by holding the tip array at a fixed potential and varying the voltage applied to individual electrodes.

3:54PM C12.00008 Channel-like conduction in $LaAlO_3/SrTiO_3$ heterointerfaces , BEENA KALISKY, Bar-Ilan University and Stanford University, ERIC SPANTON, HILARY NOAD, JOHN KIRTLEY, CHRISTOPHER BELL, HIROKI SATO, YANWU XIE, YASUYUKI HIKITA, Stanford University, CARSTEN WOLTMANN, GEORG PFANZELT, RAINER JANY, Max-Planck Institute, HAROLD HWANG, Stanford University, JOCHEN MANNHART, Max-Planck Institute, KATHRYN MOLER, Stanford University — $LaAlO_3/SrTiO_3$ (LAO/STO) heterostructures exhibit metallic conduction at the interface. Many studies of LAO/STO properties are done by transport measurements which measure conductance over macroscopic areas of the sample or device. Local information about the electronic transport is crucial to the understanding of such new materials. We use scanning SQUID microscopy to map the magnetic field locally generated by current flowing at the interface in several LAO/STO samples. We find that the conduction is non-homogeneous and channel-like on the scale of microns and that the stripes/channels are related to tetragonal domains formed in the STO below $\sim$ 105K. We will describe the details of this exciting observation and its impact on transport studies of the LAO/STO interface.

4:06PM C12.00009 Investigation of Current Channels at the Interface between Complex Oxide Heterostructures , AARON ROSENBERG, JOHN KIRTLEY, ERIC SPANTON, CHRISTOPHER WATSON, EMILIANO DI GENNARO, Stanford University, UMBERTO SCOTTI DI UCCIO, CARMELA ARUTA, FRANCESCO TAFURI, FABIO MILETTO GRANOZIO, CNR-SPIN, KATHRYN MOLER, Stanford University — The interface between $SrTiO_3$ and $LaAlO_3$, both perovskite oxide insulators, supports metallic and superconducting states under certain conditions. Previous unpublished data by Kalisky et al. shows spatial variation in the current flow in these interfaces, including enhanced conductivity associated with structural domains. The microscopic origin of this variation in conductivity is unknown. We extend the previous work to $LaGaO_3/SrTiO_3$, and $NdGaO_3/SrTiO_3$ interfaces, observe similar stripe-like modulations in the current flow, and study their temperature and frequency dependence. Additionally, we plan to study how the current channels in $LaAlO_3/SrTiO_3$ change under a uniaxial strain. Investigation of these spatial variations may improve our understanding of the relationship between structure and conductivity in complex oxide interfaces.

4:18PM C12.00010 Broadband THz Generation and Detection at 10 nm Scale[1] , YANJUN MA, MENGCHEN HUANG, JEREMY LEVY, U. of Pittsburgh, SANGWOO RYU, CHUNG WUNG BARK, CHANG-BEOM EOM, U. of Wisconsin-Madison — The terahertz region of the electromagnetic spectrum (0.1 THz-10 THz) probes a wealth of information relevant for material, biological, medical and pharmaceutical sciences, as well as applications in chemical sensing and homeland security. To date, there have been no methods capable of controlling THz radiation at scales relevant for single molecules. Here we report the generation and detection of broadband terahertz radiation from 10-nm-scale nanojunctions which are "sketched" at the interface of $LaAlO_3/SrTiO_3$ (LAO/STO) heterostructure with a conductive atomic force microscope (c-AFM) tip. The nonresonant $\chi^{(3)}$ process is characterized for a single nanojunction structure, which is nonlienar electronic response to both the static field cross the junction and the optical field illuminated the junction. The same mechanism can result in the generation and detection of broadband THz radiation. This unprecedented control of terahertz radiation, on a scale of four orders of magnitude smaller than the diffraction limit, creates a pathway toward ultra-high-resolution THz imaging, single-molecule fingerprinting, spectroscopic characterization of catalysts, and other applications.

[1]The authors acknowledge support from AFOSR - FA9550-12-1-0268 (J. L.), AFOSR FA9550-12-1-0342 (C. -B. E.) and the National Science Foundation through grants DMR-1104191 (J. L.) and DMR-1234096 (C. -B. E.).

4:30PM C12.00011 Extraordinary two-dimensional charge transport at Co_2YSi (Y=Mn,Fe)-$SrTiO_3$ Interface[1] , P.K. ROUT, HIMANSHU PANDEY, ANUPAM GULERIA, P.C. JOSHI, Z. HOSSAIN, R.C. BUDHANI[2], Indian Institute of Technology Kanpur, India — We present extraordinary charge transport in epitaxial thin films of Co_2MnSi and Co_2FeSi grown on $SrTiO_3$, which shows remarkably low residual resistivity ($\approx 10^{-7}\Omega$cm), giant residual resistivity ratio (as high as 1680) and high mobility ($\approx 10^4$ $cm^2V^{-1}s^{-1}$). Furthermore, such unusual behavior is not observed in films deposited on other cubic oxide substrates of comparable lattice parameters. The thickness dependent study establishes the presence of an electrically more conducting interfacial layer. We believe that a possible mechanism for the electronic behavior of the interface lies in a significant band bending at the interface in addition to the defects due to redox reaction of energetic particles during film growth. We compare our results with the behavior of recently discovered two dimensional electron gas (2DEG) at $LaAlO_3/SrTiO_3$ interface. The strong magnetic character of Heusler alloys combined with their metallicity adds a new dimension to 2DEG problem and makes it potentially important for spintronics applications.

4:42PM C12.00012 Epitaxial Photoactive $CoO/SrTiO_3$ on Si(001) , ALEX DEMKOV, HOSUNG SEO, THONG NGO, AGHAM POSADAS, SON HOANG, MARTIN MACDANIEL, The University of Texas, DIRK UTESS, DINA TRYIYSO, GLOANLFOUNDRIES, BUDDIE MULLINS, JOHN EKERDT, The University of Texas — Cobalt oxide (CoO) films were grown epitaxially on Si(001) by atomic layer deposition (ALD) using a thin (1.6 nm) buffer layer of strontium titanate (STO) grown by molecular beam epitaxy (MBE). Reflection high-energy electron diffraction, X-ray diffraction, and cross sectional scanning transmission electron microscopy were performed to characterize the crystalline structure of the films. The CoO films were found to be crystalline as-deposited even at the low growth temperature with no evidence of Co diffusion into Si. *In-situ* X-ray photoelectron spectroscopy (XPS) was used to measure the band alignment of the two heterojunctions, CoO/STO and CoO/TiO_2. The experimental band alignment is compared to electronic structure calculations using density functional theory.

4:54PM C12.00013 Two Dimensional Electron Gas and Rashba Effect at the Perovskite Polar Surface of $KTaO_3$, S. SATPATHY, K.V. SHANAVAS, Department of Physics & Astronomy, University of Missouri, Columbia — Using density-functional calculations, we study the formation of the 2DEG and the Rashba effect at the polar surface of the perovskite oxide $KTaO_3$, in which the 2DEG has been recently observed [1]. While the formation of the subbands are similar to the polar interface of $LaAlO_3$/ $SrTiO_3$ [2], we find that atomic relaxations play a significant role here in determining its properties. The relaxations substantially weaken the electric field due to the polar structure, reducing electron density at the surface layer. Quite significantly, we find that the lattice relaxations suppress the surface induced asymmetry in the electronic wavefunctions close to the surface, which can explain the lack of significant Rashba splitting in experiments, despite the presence of heavy elements. With a tight-binding model that includes the asymmetry-controlled hopping, we find that the Rashba effect is present only for bands with certain orbital character, allowing for its possible gate control by tuning the occupancies of the various subbands. Density-functional studies with an applied electric field support these results.

5:06PM C12.00014 2 dimensional electron gas in chemically stable $SrSnO_3/KTaO_3$ interface , HYUKWOO KWON, CHULKWON PARK, KOOKRIN CHAR, Department of physics and astronomy, Seoul National University, MATERIALS & DEVICES PHYSICS LAB. TEAM — Recent 2DEGs are mostly formed at the interface of $LaAlO_3/SrTiO_3$(LAO/STO) system, which is explained by the polar catastrophe mechanism. Because of large propensity of oxygen vacancy formation in $SrTiO_3$, there remains a possibility that the origin of 2DEG of LAO/STO system may stem from extra charge of oxygen vacancy of $SrTiO_3$, not from the polar layer of $LaAlO_3$. In this presentation, we report the realization of 2DEG at the interface of $SrSnO_3/KTaO_3$(SSO/KTO), which is chemically stable due to extremely stable oxygen stoichiometry. This $SrSnO_3/KTaO_3$ heterosturcture was epitaxially grown by puled laser deposition and the interface was found atomically matched by transmission electron microscope and reciprocal space mapping. We measured the magnetic property of SSO/KTO heterostructure and acquired a large ferromagnetic signal, which is unchanged in the temperature range of 4$\sim$300 K by SQUID magnetometer measurement. As $SrSnO_3$ and $KTaO_3$ are non-magnetic materials, this ferromagnetic signal may result from 2DEG at the interface of SSO/KTO. We hope our results can shed lights on the exact mechanism of 2DEGs that are formed at oxide interfaces.

5:18PM C12.00015 Correlation enhanced effective mass of two-dimensional electrons in $Mg_xZn_{1-x}O/ZnO$ heterostructures , YUICHI KASAHARA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, University of Tokyo, YUGO OSHIMA, RIKEN, JOSEPH FALSON, YUSUKE KOZUKA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, University of Tokyo, ATSUSHI TSUKAZAKI, Department of Materials Science, University of Tokyo, MASASHI KAWASAKI, YOSHIHIRO IWASA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, University of Tokyo — $Mg_xZn_{1-x}O/ZnO$ provides extremely clean two-dimensional electron systems (2DESs) that exhibit the integer and fractional quantum Hall effects, as in GaAs-based heterostructures. The uniqueness of $Mg_xZn_{1-x}O/ZnO$, compared with the GaAs-based heterostructures, lies in the fact that such clean 2DESs emerge with effective mass of electrons in ZnO, which is over four times higher than that in GaAs, indicating that the effects of electron correlation are expected to be much more pronounced than their GaAs counterparts. Here we show the results of combined magnetotransport and cyclotron resonance experiments on 2DESs confined in $Mg_xZn_{1-x}O/ZnO$ heterostructures. We have observed a steep enhancement of transport masses (m^*_{tr}) with decreasing carrier density, whereas the effective masses determined by the cyclotron resonance (m^*_{CR}) are independent of the carrier density and are comparable to the effective mass of bulk ZnO. The discrepancies between m^*_{tr} and m^*_{CR} directly gauges the strength of the electron-electron interactions. Therefore, observed enhancement of m^*_{tr}, which exceeds m^*_{CR} by nearly 60%, is a direct consequence the electron-electron interactions. [1] Y. Kasahara et al., Phys. Rev. Lett., Accepted.

Session C13 DMP: Focus Session: Topological Materials - Search for New Materials 315 - Seongshik Oh, Rutgers University

2:30PM C13.00001 Structure and physical properties of Antimony Asenide: a first principle study[1]

, DAT DO, S. D. MAHANTI, Department of Physics and Astronomy, Michigan State University — The group V elements, Sb, As and Bi have attracted renewed attention especially after the discovery of the strong topological insulator $Bi_{1-x}Sb_x$. While the mixing of group V elements are thought to be random, recently, Shoemaker et al., arXiv:1210.1986 [cond-mat.mtrl-sci], using single-crystal and high-resolution synchrotron x-ray diffraction, and neutron and x-ray pair distribution function analysis, show that SbAs has chemical ordering. Here we present a detailed theoretical study of the structure and physical properties of SbAs. Our cluster expansion calculation predicts the existence of the chemical ordering, in agreement with experiment. The electronic structure calculations reveal that SbAs is a semimetal with a pseudo gap. We also discuss the similarities and differences of SbAs with its two end-members Sb and As and the Sb-Bi system (bulk), and compare the surface electronic structures of all these systems.

2:42PM C13.00002 ABSTRACT WITHDRAWN –

2:54PM C13.00003 Driving conventional semiconductors into topological insulating phase

, KAI CHANG, SKLSM, Institute of Semiconductors, Beijing, China, KAI CHANG TEAM, DONG ZHANG TEAM, WENKAI LOU TEAM, M. S. MIAO COLLABORATION — Topological insulator (TI) is a central issue of condensed matter physics and has attracted intensive interests recently. TI is a new state of quantum matter possessing insulating bulk and metallic edges. This novel property is caused by a strong spin-orbit interactions (SOIs) in TIs. Usually the topological insulators are narrow band gap systems containing heavy atoms. This requirement limits the members of TIs and its widespread application heavily. Electric fields can drive topological insulator transition in HgTe quantum wells and induces the intrinsic spin Hall effect [1], and can also be used to control surface magnetism of topological insulators [2,3]. More importantly, that conventional semiconductors can be driven into topological insulating phase utilizing the interface polarization induced electric field [4]. We demonstrate theoretically this possibility in GaN/InN/GaN systems. We are moving toward more commonly used semiconductors, such as Silicon.

3:06PM C13.00004 Nontrivial spin-texture of the surface states in topological crystalline insulator SnTe

, YUNG JUI WANG, HSIN LIN, Northeastern U. (NU), WEI-FENG TSAI, National Sun Yat-sen U., Taiwan, SU-YANG XU, M. Z. HASAN, Princeton U., A. BANSIL, NU — We present a first principles investigation of the nontrivial surface states and their spin-texture in the topological crystalline insulator SnTe[1,2]. The surface state dispersion on the [001] surface is found to support four Dirac-cones centered along the intersection of the mirror plane and the surface plane. The in-plane spin-texture displays helicity and indicates a nontrivial mirror Chern number of -2, distinct from that of -1 in a Z_2 topological insulator such as Bi/Sb. The surface state dispersion and the associated spin-texture are shown to provide an experimental route for determining the presence of a nontrivial Chern number. Work supported by the US DOE.

3:18PM C13.00005 Flat Chern Band in a Two-Dimensional Organometallic Framework[1]

, ZHENG LIU, ZHENG-FEI WANG, University of Utah, JIA-WEI MEI, ETH Zurich, YONG-SHI WU, FENG LIU, University of Utah — By combining exotic band dispersion with nontrivial band topology, an interesting type of band, namely the flat chern band (FCB), has recently been proposed, in which carriers experience strong Coulomb interaction as well as topological frustration that in together spawn unprecedented topological strongly-correlated electronic states, such as high-temperature fractional quantum hall state. Despite the proposal of several theoretical lattice models, however, it remains a doubt whether such a "romance of flatland" could exist in a real material. Here, we present a first-principles design to realize a nearly FCB right around the Fermi level in a two-dimensional (2D) Indium-Phenylene Organometallic Framework (IPOF). Our design in addition provides a general strategy to synthesize topologically nontrivial materials in virtue of organic chemistry and nanotechnology.

3:30PM C13.00006 Self-assembled structurally complex double-layers of 3-HPLN on Cu(111)

, SUMIT BENIWAL, DONNA KUNKEL, Department of Physics and Astronomy, University of Nebraska - Lincoln, Lincoln, NE 68588, JAMES HOOPER, SCOTT SIMPSON, EVA ZUREK, Department of Chemistry, State University of New York at Buffalo, 331 Natural Sciences Complex, Buffalo, NY 14360, AXEL ENDERS, Department of Physics and Astronomy, University of Nebraska - Lincoln, Lincoln, NE 68588 — The self-assembly of 3-Hydroxyphenalenone (3-HPLN) on metal surface has been studied with scanning tunneling microscopy and first principles theory. 3-HPLN belongs to the group of topological ferroelectric organics, where the electric polarization is related to the hydrogen bonds between the molecules. It is observed that the structure of the self-assembled 2D networks is strongly dependent of the substrate material and the preparation conditions. Of particular interest in this presentation is the chiral Kagome lattices of 3-HPLN observed after annealing on Cu(111). A unique feature of the molecular network is the CH-pi bond formation between flat-lying molecules and molecules attached perpendicular to the surface. It will be demonstrated that the addition of a second layer on the first monolayer of 3-HPLN triggers a structural reorganization in the first layer, to form a complex double layer structure that is not merely the addition of two single layers. The chiral pores in the film can serve as a host or a template for metal nanoparticles, such as Fe. The so-obtained hybrid nanostructures might be a useful milestone towards self-asembled metal-organics multiferroics.

3:42PM C13.00007 Topological Insulators: A New Platform for Fundamental Science and Applications

, ARUN BANSIL, Northeastern University — Topological insulators constitute a new phase of quantum matter whose recent discovery has focused world-wide attention on wide-ranging phenomena in materials driven by spin-orbit coupling effects well beyond their traditional role in determining magnetic properties. I will discuss how by exploiting electronic structure techniques we have been able to predict and understand the characteristics of many new classes of binary, ternary and quaternary topologically interesting systems. [1-4] The flexibility of chemical, structural and magnetic parameters so obtained is the key ingredient for exploring fundamental science questions, including novel spin-textures and exotic superconducting states, as well as for the realization of multi-functional topological devices for thermoelectric, spintronics, information processing and other applications. [5-7] I will also highlight new insights that have been enabled through our material-specific modeling of angle-resolved photoemission (ARPES) and scanning tunneling (STS) spectroscopies of topological surface states, including effects of the photoemission and tunneling matrix element, which is well-known to be important for a robust interpretation of various highly resolved spectroscopies. 4:18PM C13.00008 Metal-Insulator Transition in Epitaxial Pyrochlore Iridates $Bi_2Ir_2O_7$ thin Films

, JIUN-HAW CHU, JIAN LIU, DI YI, C. RAYAN-SERRAO, S. SURESHA, XAVI MARTI, Department of Physics and Department of Materials Science and Engineering, University of California, Berkeley, SCOTT RIGGS, MAX SHAPIRO, FISHER IAN, Department of Applied Physics and Geballe Laboratory for Advanced Materials, Stanford University, R. RAMESH, Department of Physics and Department of Materials Science and Engineering, University of California, Berkeley — Recently there is a surge of interest in searching for topological order in correlated electronic systems such as transition metal oxides. The strong spin-orbit interaction of 5d electrons and the geometric frustration in the crystal lattice make the pyrochlore iridate($A_2Ir_2O_7$) an ideal candidate to achieve this goal. Pioneering experiments on bulk polycrystalline and single crystal samples revealed a temperature dependent metal-insulator transition coupled to a long range magnetic order, and the transition temperature can be tuned by either A-site ionic radius or an external pressure. In this talk we present our efforts to understand and control the metal-insulator transition and the underlying electronic structure of pyrochlore iridates via epitaxial $Bi_2Ir_2O_7$ thin films. Bulk $Bi_2Ir_2O_7$ is located at the metallic side of the phase diagram. However as the film's thickness decreases the transport evolves from a metallic to a strongly localized character. Resonant X-ray spectroscopy suggests that the density of states near Fermi level is dominated by the Ir J_eff=1/2 states. Intriguingly, the magnetoresistance shows a linear field dependence over a wide range of fields at low temperatures, which is possibly consistent with the existence of Dirac nodes.

4:30PM C13.00009 Na_2IrO_3 as a Novel Relativistic Mott Insulator with a 340 meV Gap

, RICCARDO COMIN, G. LEVY, I. ELFIMOV, A. DAMASCELLI, Quantum Matter Institute, UBC, Vancouver, Canada, D. STRICKER, J. HANCOCK, D. VAN DER MAREL, Université de Genève, Switzerland, Y. SINGH, Indian Institute of Science Education and Research, Mohali, India, P. GEGENWART, Georg-August-Universitat Göttingen, Germany — We have studied Na_2IrO_3 by ARPES, optics, and band structure calculations in the local-density approximation (LDA). The weak dispersion of the Ir 5d-t_{2g} manifold highlights the importance of structural distortions and spin-orbit coupling (SO) in driving the system closer to a Mott transition. We detected an insulating gap $\Delta_{gap} \simeq 340$ meV which, at variance with a Slater-type description, is already open at 300 K and does not show significant temperature dependence even across $T_N \simeq 15$ K. An LDA analysis with the inclusion of SO and Coulomb repulsion U revealed that, while the prodromes of an underlying insulating state are already found in LDA+SO, the correct gap magnitude can only be reproduced by LDA+SO+U, with $U = 3$ eV. This establishes Na_2IrO_3 as a novel type of Mott-like correlated insulator in which Coulomb and relativistic effects have to be treated on an equal footing.

4:42PM C13.00010 Single surface state at a strongly correlated electronic structure in Na_2IrO_3: a candidate d-electron topological insulator

, QIANG WANG, University of Colorado at Boulder, Los Alamos National Laboratory, YUE CAO, JUSTIN WAUGH, University of Colorado at Boulder, TONGFEI QI, OLEKSANDR KORNETA, GANG CAO, University of Kentucky, DANIEL DESSAU, University of Colorado at Boulder — We have performed angle-resolved photoemission spectroscopy (ARPES) on Na_2IrO_3, a 5d transition metal oxide (TMO) which is a strong insulator with a honeycomb lattice structure and has been theoretically proposed as a candidate for a new class of topological insulators (TIs). The near E_F electronic structure of Na_2IrO_3 was carefully mapped, which shows an overall agreement to the first-principle calculations with spin-orbit (SO) coupling and electron correlation (U), though certain discrepancy remains. Specifically, we found an extra electron-like pocket near the Fermi level with Dirac-cone-like dispersion around Γ point. The further photon energy dependent studies show no k_z-dispersion of this electron-like pocket, and the metal deposition studies show a great enhancement and sharpening of this feature. These results confirm its surface state nature and suggest a possible single topological surface state at the Brillouin zone (BZ) center in Na_2IrO_3.

4:54PM C13.00011 Multiple Topological phase transitions induced by magnetic ordering in $Cd_2Ru_2O_7$[1]

, HONGMING WENG, QUANSHENG WU, ZHONG FANG, XI DAI, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, T03 GROUP, INSTITUTE OF PHYSICS, CHINA TEAM — The magnetic and electronic structures of pyrochlore Ruthenates $Cd_2Ru_2O_7$ are studied by means of first principle calculation. We find that the paramagnetic phase stabilized in high temperature is a three dimensional Z_2 topological insulator. While in low temperature the all-in/all-out type anti-ferromagnetic order appears, which leads to three different topologically non-trivial phase can be stabilized upon cooling, namely the axion insulator, Weyl semi-metal and intrinsic polarization phases. The detailed evolution of both bulk and surface electronic structures as the function of magnetic order parameter are obtained. Based on the above observations we propose several experimental consequences, which can be detected by further experiments.

5:06PM C13.00012 Topological phases in layered pyrochlore oxide thin films along the [111] direction[1] , XIANG HU, The University of Texas at Austin, TX, 78712, ANDREAS RÜEGG, University of California, Berkeley, CA 94720, GREGORY A. FIETE, The University of Texas at Austin, TX, 78712 — We theoretically study a multi-band Hubbard model of pyrochlore oxides of the form $A_2B_2O_7$, where B is a heavy transition metal ion with strong spin-orbit coupling, in a thin film geometry orientated along the [111] direction. Along this direction, the pyrochlore lattice consists of alternating kagome and triangular lattice planes of B ions. We consider a single kagome layer, a bilayer, and the two different trilayers. As a function of the strength of the spin-orbit coupling, the direct and indirect d-orbital hopping, and the band filling, we identify a number of scenarios where a non-interacting time-reversal invariant Z_2 topological phase is expected and we suggest some candidate materials. We study the interactions in the half-filled d-shell within Hatree-Fock theory and identify parameter regimes where a zero magnetic field Chern insulator with Chern number ± 1 can be found. The most promising geometries for topological phases appear to be the bilayer which supports both a Z_2 topological insulator and a Chern insulator, and the triangular-kagome-triangular trilayer which supports a relatively robust Chern insulator phase.

5:18PM C13.00013 Samarium Hexaboride - First True 3D Topological Insulator[1] , STEVEN WOLGAST, ÇAĞLIYAN KURDAK, KAI SUN, JAMES ALLEN, Dept. of Physics, University of Michigan, ZACHARY FISK, Dept. of Physics and Astronomy, University of California, Irvine — Although many important breakthroughs in the study of topological states of matter have been achieved within the last few years, a very important link still remains missing–the experimental discovery of a true 3D topological insulator. Materials currently known to have topological surface states (e.g. $Bi_{1-x}Sb_x$, Bi_2Se_3 and Bi_2Te_3) are also bulk conductors, and thus do not have a well-defined topological index. Recent calculations of the heavy-fermion Kondo insulator Samarium Hexaboride (SmB_6) have predicted the possibility of in-gap topological surface states in this material. Meanwhile, the conjectured existence of a topologically-protected surface state in SmB_6 could resolve many of the long-standing puzzles surrounding its low-temperature transport properties. Here we study the transport properties of SmB_6 with a novel configuration designed to distinguish bulk-dominated conduction from surface-dominated conduction. We find that SmB_6 is a true topological insulator with an insulating bulk and a metallic surface. This discovery resolves the standing puzzles about the strange transport behavior of this material, and it provides the first material in which transport properties of a 3D topological state can be studied.

Session C14 DMP GMAG: Focus Session: Magnetic Oxide Superlattices and Multiferroics 316

- Susanne Stemmer, UC Santa Barbara

2:30PM C14.00001 First-principles study of spin-lattice and spin-phonon couplings in $SrMnO_3/LaMnO_3$ superlattice , YUANJUN ZHOU, KARIN RABE, Rutgers University — We have studied the influence of epitaxial strain on magnetic orderings and the couplings between the spin and optical phonons in $SrMnO_3/LaMnO_3$ superlattices using first principles. We first couple octahedral rotations with structural relaxations in ferromagnetic (FM), A-type antiferromagnetic (A-AFM) and C-type AFM (C-AFM) states, and obtain the sequence of magnetic phases with epitaxial strain. We also find that oxygen octahedral rotations lower the ground state energy but do not destroy the strain induced magnetic phase transitions. Next, the zone-center phonon modes in FM, A-AFM, and C-AFM states are computed using the frozen phonon method. A substantial increase of the coupling strength between the spin and the lowest polar mode is observed for tensile strains. From the analysis of the eigenvectors, the effect is inferred to be the consequence of the enhanced amplitudes of oxygen atoms in the phonon mode. Finally, spin-phonon coupling parameters are computed in a Heisenberg formulism. They reveal the changes in exchange couplings due to specific atomic displacements or phonon modes, as well as the inequality of the out-of-plane exchange couplings across LaO layers and across SrO layers, the latter being the result of the artificial structuring in the superlattice.

2:42PM C14.00002 Charge transfer and magnetism in $(LaNiO_3)_n/(LaMnO_3)_2$ superlattices , JASON HOFFMAN, Argonne National Laboratory, I-CHENG TUNG, Northwestern University, BRITTANY NELSON-CHEESEMAN, MING LIU, JOHN FREELAND, ANAND BHATTACHARYA, Argonne National Laboratory — Interfaces in solids have been an enduring them in materials physics, where dimensionality and proximity effects cooperate to create interfacial states that are distinct from their bulk counterparts. In this work, we investigate the interfacial ferromagnetism induced in the the paramagnetic metal $LaNiO_3$ via proximity to the antiferrmagnetic insulator $LaMnO_3$. We fabricated a series of $(LaNiO_3)_n/(LaMnO_3)_2$ ($2 \leq n \leq 5$) digital superlattices on (001) $SrTiO_3$ substrates using ozone-assisted molecular beam epitaxy. The total superlattice thickness is maintained at $\sim$30 nm by varying the number of superlattice periods. X-ray absorption and x-ray magnetic circular dichroism measurements at the Mn and Ni L-edges confirm the presence of charge-transfer at the $LaNiO_3/LaMnO_3$ interface, with magnetism residing on both Mn and Ni sites. Magnetotransport measurements performed on superlattices with $n \leq 3$ show insulating behavior between 5 K and 300 K, while samples with $n = 4$,5 are metallic. We observe an anomalous Hall effect in the sample with $n = 4$, that vanishes in the more metallic $n = 5$ sample. We discuss possible models for the electronic and magnetic behavior of $LaNiO_3$.

2:54PM C14.00003 Designing ferromagnetism in early transition metal oxides in bulk and superlattice forms[1] , HUNG DANG, ANDREW MILLIS, Department of Physics, Columbia University — The circumstances under which early transition metal oxides could exhibit ferromagnetism are determined using density functional plus single-site dynamical mean field methods. Particular attention is paid to the consequences of the $GdFeO_3$ distortion and other octahedral rotations. Ferromagnetism is favored by the combination of intermediate carrier concentration (formal valence $\sim d^{1.5}$) and large tilt angle. The decrease of $GdFeO_3$ distortion amplitude with hole doping away from d^2 is shown to keep the bulk solid solution $La_{1-x}Sr_xVO_3$ outside of the ferromagnetic regime. In superlattices such as $(LaVO_3)_m(SrVO_3)_1$, carrier concentration and tilt angle may be decoupled, potentially enabling ferromagnetism as suggested by experiment[1].

3:06PM C14.00004 Designing Magnetism in Oxide Superlattices[1]

, ANDREW MILLIS, Department of Physics, Columbia University — Dramatic improvements in pulsed laser deposition and oxide molecular beam epitaxy suggest that it may be possible to create "designer" materials with desired correlated electron properties. This talk presents the results of theoretical studies based on the density functional plus dynamical mean field approximation aimed at determining design rules for creating or optimizing magnetism in oxide superlattices. Among the topics covered will be the physics of long-period antiferromagnetic states in nickelate-based heterostructures and the relation of strain-induced octahedral rotations in creating ferromagnetic states in vanadate-based superlattices. We show in particular how appropriately designed superlattices may lead to structure-doping combinations which do not occur in bulk solid solutions but which can produce high Curie temperature ferromagnetism. Limitations of present theoretical capabilities and opportunities and needs for conceptual, methodological and algorithmic improvements will also be discussed. This work is based in part on collaborations with C. Marianetti, B. Lao and H-T Dang.

[1]Supported by Basic Energy Sciences Division of the US Department of Energy under grant ER-046169

3:42PM C14.00005 Tunable spin-density-wave order in nickelate heterostructures[1]

, A. FRANO, Max Planck Insitute for Solid State Research, E. SCHIERLE, Helmholtz-Zentrum Berlin fuer Materialien und Energie, BESSY II, M. HAVERKORT, Y. LU, M. WU, S. BLANCO-CANOSA, U. NWANKWO, A.V. BORIS, P. WOCHNER, G. CRISTIANI, H.U. HABERMEIER, Max Planck Insitute for Solid State Research, V. HINKOV, Quantum Matter Institute, University of British Columbia, E. BENCKISER, Max Planck Insitute for Solid State Research, E. WESCHKE, Helmholtz-Zentrum Berlin fuer Materialien und Energie, BESSY II, B. KEIMER, Max Planck Insitute for Solid State Research — Antiferromagnetic spin-density-wave (SDW) order in metals has been proposed as the basis for a new generation of spintronic devices. However, SDWs have been observed only in a few materials to-date, and it has proven difficult to systematically control their properties. Using resonant x-ray diffraction, we demonstrate SDW order in epitaxial thin films and superlattices based on metallic RNiO$_3$ with R = La, Nd, Pr. The materials remain highly conductive in the SDW state, and the amplitude of concomitant charge order is dramatically reduced with respect to their bulk analogs. We also show that the SDW polarization is tunable through two independent control parameters – epitaxial strain and dimensional confinement of the conduction electrons. Nickelate heterostructures are thus a powerful new model platform for SDW physics and antiferromagnetic spintronics.

3:54PM C14.00006 Magnetic and orbital order in (RMnO3)n/(AMnO3)2n superlattices[1]

, SHUAI DONG, University of Tennessee, Knoxville; Oak Ridge National Laboratory; Southeast University, China, QINFANG ZHANG, Yancheng Institute of technology, China, ELBIO DAGOTTO, University of Tennessee, Knoxville; Oak Ridge National Laboratory — The magnetic and orbital orders in (RMnO3)n/(AMnO3)2n (R: rare earths; A: alkaline earths, n=1 and 2) superlattices have been studied using both the double-exchange model and density functional theory calculations. For large bandwidth manganites, the A-type antiferromagnetic order is found to be robust when the superlattices are grown on a SrTiO3 substrate, as in recent experiments on (LaMnO3)n/(SrMnO3)2n. In addition, a C-type antiferromagnetic state is predicted for these superlattices when using substrates like LaAlO3 with smaller lattice constants. The physical mechanism for the stabilization of the A- and C- magnetic transitions is driven by the orbital splitting of the x2-y2 and 3z2-r2 orbitals, which is induced by the Q3 mode of Jahn-Teller distortions created by the strain induced by the substrates. If the superlattices were prepared employing narrow bandwidth manganites, several non-homogeneous magnetic profiles are predicted to exist, highlighting the importance of carrying out investigations in this mostly unexplored area of research. [1] S. Dong, Q.F. Zhang, S. Yunoki, J.-M. Liu, and E. Dagotto, Phys. Rev. B in press. (ArXiv: 1211.1943) [2] Q.F. Zhang, S. Dong, B.L. Wang, and S. Yunoki, Phys. Rev. B 86, 094403 (2012).

4:06PM C14.00007 Half-Metallic Ferromagnetism in $LaAlO_3/SrMnO_3$ Nanosheet Superlattices

, FANG HOU, TIAN-YI CAI, SHENG JU, MING-RONG SHEN, Department of Physics, Soochow University, Suzhou, PR China — Based on first-principle density-functional theory, we have revealed a robust half-metallic ferromagnetism in $LaAlO_3/SrMnO_3$ nanosheet supperlattices. Interface electronic reconstruction, where electrons transfer from the $(LaO)^+$ layer to the adjacent $(MnO_2)^0$ layer, is found to lead to the partially occupied e_g orbitals at the Mn sites and the half-metallic state in nn-type superlattice via the Zener double-exchange mechanism. On the other hand, holes transfer from $(AlO_2)^-$ layer to $(SrO)^0$ layer and reside mainly at oxygen sites in $SrMnO_3$, leading to either the preserved G-type AFM ordering in pp-type superlattices or complex magnetic ordering in np-type superlattices. When these systems transist to ferromagnetic ordering by an external magnetic field, an obvious change of electronic states at the Fermi level is found, suggesting a large magnetoresistive effect therein.

4:18PM C14.00008 Magnetoelectric coupling across the BiFeO3/manganite interface

, DI YI, JIAN LIU, UC berkeley, PU YU, Physics Department, Tsinghua University, WEIDONG LUO, Materials Science and Technology Division, Oak Ridge National Laboratory, SURESHA JAGANATHA, National Center for Electron Microscopy, LBNL, GUNEETA BHALLA, UC berkeley, GUNNAR PALSSON, ELKE ARENHOLZ, Advanced Light Source, LBNL, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, RAMAMOORTHY RAMESH, UC Berkeley — Artificially constructed heterointerfaces between strongly correlated systems provide researchers an extensive playground to investigate the novel physics and fascinating states. Recently it has been shown that an exotic magnetoelectric coupling exists at the ferromagnetic manganite La0.7Sr0.3MnO3 (LSMO) and the multiferroic BiFeO3 (BFO) interface, in which the magnetization, the coercive field and exchange bias of LSMO can be controlled by the ferroelectric polarization of BFO. First principle calculations illustrate that different charge screening of polarization lead to different coupling mechanism. To further explore the magnetoelectric coupling, we also investigate the heterostructure between BiFeO3 and half-doped manganite La0.5Ca0.5MnO3 (LCMO). Unlike LSMO which is a ferromagnetic metal, LCMO thin film exhibits a paramagnetic semiconducting behavior in the temperature range we studied, yet the magnetization of LCMO in an applied magnetic field enhanced by a factor of 2 by switching the ferroelectric polarization. X-ray absorption data reveals the different valence states of Mn, consistent with the charge screening model.

4:30PM C14.00009 Engineering the magnonic and spintronic response of $BiFeO_3$ films by epitaxial strain

, MAXIMILIEN CAZAYOUS, P. ROVILAIN, Laboratoire Materiaux et Phenomenes Quantiques, Univ. Paris Diderot (France), J. JURASZEK, Groupe de Physique des Materiaux, Univ. Rouen (France), A.K. ZVEZDIN, Prokhorov General Physics Institute, Russian Academy of Sciences, Moscow (Russia), L. BELLAICHE, Physics Department, University of Arkansas, Fayetteville (Usa), B. DKHIL, Laboratoire SPMS, Ecole Centrale Paris, Chatenay-Malabry (France), A. BARTHELEMY, M. BIBES, Unite Mixte de Physique CNRS/Thales, Palaiseau et Universite Paris-Sud, Orsay (France) — Multiferroics display cross-coupling effects between ferroelectricity and magnetism. $BiFeO_3$ has many properties such as a cycloidal magnetic order in the bulk and conductive domain walls, most related to its ferroelectric order. However its antiferromagnetic properties have not been investigated deeply in thin films. Here we show how the strain engineering can be applied to modify its static and dynamic magnetic properties. We have used Mossbauer and Raman spectroscopies combined with Landau-Ginzburg theory and effective Hamiltonian calculations. We show that the cycloidal spin modulation that exists at low compressive strain is driven towards collinear antiferromagnetism at both tensile and compressive high strain. Morover, we find that the spin excitations are entirely modified with the suppression of the magnon modes as strain increases and that the strain modifies the average spin angle from in-plane to out-of-plane. Our results illustrate the power of strain engineering for designing functional materials on demand.

4:42PM C14.00010 Order Parameter Interaction at Interfaces and Domain Walls in a BiFeO3 Thin Film[1] , YOUNG-MIN KIM, MARK OXLEY, Oak Ridge National Laboratory, ANNA MOROZOVSKA, EUGENE ELISEEV, National Academy of Sciences of Ukraine, PU YU, University of California Berkeley, YING-HAO CHU, National Chiao Tung University, RAMAMOORTHY RAMESH, University of California Berkeley, STEPHEN PENNYCOOK, SERGEI KALININ, ALBINA BORISEVICH, Oak Ridge National Laboratory — Atomic scale studies of the different structural, electronic, and chemical order parameters at domain walls and interfaces are vital for optimization and design of the ferroelectric-based thin film devices. In this study, we use quantitative scanning transmission electron microscopy (STEM) combined with electron energy loss spectroscopy to study atomic-scale phenomena in a multiferroic thin film heterostructures of $BiFeO_3$ (BFO) epitaxially grown on (La,Sr)MnO_3 (LSMO) layer on a $SrTiO_3$ (STO) substrate. We find that charged and uncharged domain walls, as well as interfaces to domain of different polarity, have distinct structural signatures. Charged domain walls are associated with local lattice expansion, suggesting segregation of oxygen vacancies; uncharged domain walls show increased Debye-Waller factors for Bi, suggesting structural frustration. At the LSMO/BFO interface, downward polarization direction is associated with change in local valence state of near-interface Mn cations and lattice expansion.

4:54PM C14.00011 Probing of spontaneous polarization screened by defect-induced free carriers in gallium ferrite thin films , S.H. OH, Ewha Womans University, R.H. SHIN, Ewha Womans University,CNRS-EWHA International Research Center, W. JO[1], Ewha Womans University, C. LEFEVRE, Ewha Womans University,CNRS-EWHA International Research Center, Institute of Physics and Chemistry of Materials of Strasbourg, F. ROULLAND, A. THOMASSN, C. MENY, N. VIART, Institute of Physics and Chemistry of Materials of Strasbourg — Gallium ferrite, GaFeO3 (GFO), is known as a potential multiferroic material with spontaneous polarization and magnetization [1,2]. However, it was difficult to measure the polarization reversal of GFO thin films because conduction electrons screen the polarization switching responsible for ferroelectricity. Therefore, controlling charge conduction of a multiferroic material is key issue. In this study, we investigated the carrier transport behavior and the charge conduction mechanism in epitaxial GFO thin films deposited on metallic oxide-coated single crystal SrTiO3 substrates by pulsed laser deposition. Macroscopic carrier transports result showed that the interface limited model was the dominant conduction mechanism of the large leakage current and the nature of carrier transport at interface between GFO thin films and substrates was demonstrated by band profiles. Local charge conduction of GFO thin films was studied by conducting atomic force microscope. The polarization switching behavior of GFO thin films was showed by polarization-electric field curve and the positive-up-negative-down method. [1] A. Roy et al., J. Phys.: Condens. Matter 23 (2011) 325902. [2] D. Stoeffler, J. Phys.: Condens. Matter 24 (2012) 185502.

5:06PM C14.00012 Interfacial Magnetic Response of $PbZr_{0.2}Ti_{0.8}O_3$ /$La_{0.67}Sr_{0.33}MnO_3$ Heterostructures , SAN-WEN CHEN, HONGYU GUO, University of California San Diego, KARINE DUMESNIL, University H. Poincare - Nancy 1, VALERIA LAUTER, Oak Ridge National Lab, CECILIA SANCHEZ-HANKE, Brookhaven National Lab, EDWIN FOHTUNG, MOSES MARSH, OLEG SHPYRKO, ERIC FULLERTON, SUNIL SINHA, University of California San Diego — There is increasing interest in modifying magnetism by electric fields for both scientific and technological point of view. In a ferromagnetic/piezoelectric composite structure, it is reported that the electric field can alter both the Curie temperature and the magnetization in the ferromagnetic material by inducing charge accumulation or depletion at the interface.[1] To understand the detailed changes in the magnetization profile at the interface, we performed both polarized neutron reflectivity and resonant soft X-ray reflectivity measurements on an epitaxially grown $PbZr_{0.2}Ti_{0.8}O_3$ (PZT)/$La_{0.67}Sr_{0.33}MnO_3$ (LSMO) bilayer. A clear magneto-electric effect was observed below the Curie temperature of LSMO; i.e., the magnetization in LSMO decreases when the electric field was applied. The magnetization depth profile as a function of applied electric field will be presented.

5:18PM C14.00013 Investigation on valences and strains in $La_{0.7}Sr_{0.3}MnO_3/PbZr_{0.2}Ti_{0.8}$ O_3 Heterostructures , JINLING ZHOU, DISHENG CHEN, West Virginia University, ANDREAS SCHOLL, Advanced Light Source, Lawrence Berkeley National Lab, YING-HAO CHU, National Chiao Tung University, MIKEL HOLCOMB, West Virgina University — Magnetoelectric (ME) coupled materials have electric and magnetic properties coexisting and coupled together, promising novel applications. Understanding the coupling mechanisms responsible for this behavior would allow a strategic approach to device design. Our group studies the interfacial properties of the known magnetoelectric system of ferromagnetic $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) and ferroelectric $PbZr_{0.2}Ti_{0.8}$ O_3 (PZT). Through photoemission electron microscopy imagining, ME coupling was confirmed at the interface. X-ray absorption spectroscopy of Mn and Ti was taken across wedged samples of varying ferroelectric and ferromagnetic thicknesses. X-ray microdiffraction was analyzed at different thickness to investigate the strain effect on ME coupling. The effect of thickness and strain on Mn and Ti valences suggest an ideal model for improving interfacial coupling in these systems.

Session C15 GMAG DMP: Focus Session: New Frustrated Models: Theory & Materials 317 - William Ratcliff, National Institute of Standards and Technology

2:30PM C15.00001 Emergent critical phase and Ricci flow in a 2D frustrated Heisenberg model , PETER P. ORTH, Karlsruhe Institute of Technology (KIT), PREMALA CHANDRA, PIERS COLEMAN, Rutgers University, JOERG SCHMALIAN, Karlsruhe Institute of Technology (KIT) — We introduce a two-dimensional frustrated Heisenberg antiferromagnet on interpenetrating honeycomb and triangular lattices [1]. Classically the two sublattices decouple, and "order from disorder" drives them into a coplanar state. Applying Friedan's geometric approach to nonlinear sigma models, we obtain the scaling of the spin-stiffnesses governed by the Ricci flow of a 4D metric tensor. At low temperatures, the relative phase between the spins on the two sublattices is described by a six-state clock model with an emergent critical phase and two Berezinskii-Kosterlitz-Thouless (BKT) phase transitions.

2:42PM C15.00002 Pentagonal Spin Ice , PAULA MELLADO, Department of Engineering and Sciences, Universidad Adolfo Ibañez, GIA-WEI CHERN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico, USA — We study a novel version of spin ice in the Pentagonal lattice from a theoretical perspective. The coexistence of even (z=4) and odd (z=3) coordinated vertices in this network gives rise to a mixed spin ice phase where the honeycomb spin ice rule is realized at the z=3 sites and the usual spin ice with no magnetic charge occurs at the z=4 vertices. As the system cools down a phase with charge order precludes the spin ordered stage. Magnetic excitations that violate ice-rule at the z=4 vertices behave as emergent monopoles whose interaction with the background charges from z=3 sites exhibits novel dynamics.

2:54PM C15.00003 Thermodynamics of Ising Spins on the Star Lattice , DAO-XIN YAO, ZEWEI CHEN, NVSEN MA, Sun Yat-sen University — There is a new class of two-dimensional magnetic materials polymeric iron (III) acetate fabricated recently in which Fe ions form a star lattice. We study the thermodynamics of Ising spins on the star lattice with exact analytic method and Monte Carlo simulations. Mapping the star lattice to the honeycomb lattice, we obtain the partition function for the system with asymmetric interactions. The free energy, internal energy, specific heat, entropy and susceptibility are presented, which can be used to determine the sign of the interactions in the real materials. Moreover, we find the rich phase diagrams of the system as a function of interactions, temperature and external magnetic field. For frustrated interactions without external field, the ground state is disordered (spin liquid) with residual entropy 1.522 . . . per unit cell. When a weak field is applied, the system enters a ferrimagnetic phase with residual entropy ln4 per unit cell. The arXiv version of this work is arXiv:1210.1675.

3:06PM C15.00004 Field-induced multiple-Q phases in a frustrated quantum magnet , YOSHITOMO KAMIYA, CRISTIAN BATISTA, Theoretical Division, T4 and CNLS, Los Alamos National Laboratory — We study a frustrated hard-core boson model inspired by recent experiments on the field-induced quantum phase transition in the S=1 dimer antiferromagnet $Ba_3Mn_2O_8$ for a magnetic field H parallel to the c axis. We calculate the effective interactions in the low-density limit by adding the ladder diagrams and determine the ground state phase diagram near the quantum critical point. The phase diagram is very rich and includes different multiple-**Q** Bose-Einstein condensates (BECs) that combine the six degenerate incommensurate lowest-energy modes $\pm\,\mathbf{Q}_n$ ($1\leq n\leq 3$) at the quantum critical point. The multiple-**Q** states include a lattice of magnetic vortices that emerges out of frustration between the boson-boson interactions.

3:18PM C15.00005 Spin-Density-Wave Order and Slow Dynamics in $Ca_3Co_2O_6$, CRISTIAN BATISTA, YOSHITOMO KAMIYA, Theoretical Division, T4 and CNLS, Los Alamos National Laboratory — We study a frustrated quantum Ising model relevant for $Ca_3Co_2O_6$ that comprises a triangular lattice of weakly coupled ferromagnetic chains [Y. Kamiya and C. D. Batista, PRL **109**, 067204 (2012)]. Our quantum Monte Carlo simulation shows that the chains become ferromagnetic and form a three-sublattice "up-up-down" structure in the lowest temperature regime $T \leq T_{CI}$ due to a quantum effect. In contrast, long-wavelength spin-density-wave (SDW) modulations along the chains are stabilized for $T_{CI}<T<T_c$ in agreement with recent experiments. We also discuss a simple mean-field theory revealing quasi-continuous change of the modulation periodicity as a function of T and implying the existence of metastable states in the SDW phase, which explains the slow low-temperature dynamics that has been observed in $Ca_3Co_2O_6$. The closely related multiferroic materials Ca_3CoMnO_6 and Lu_2CoMnO_6 will also be discussed.

3:30PM C15.00006 Elastic and inelastic neutron scattering studies on $Sr_2FeSi_2O_7$, KAZUKI IIDA, ISRAEL KLICH, SUNGDAE JI, JOOSEOP LEE, NAOYUKI KATAYAMA, TOM JACKSON, SEUNGHUN LEE, Univeristy of Virginia, DORON BERGMAN, California Institute of Technology, SUNG CHANG, NIST Center for Neutron Research, DUC LE, Helmholtz Zentrum Berlin, ENRICO FAULHABER, ASTRID SCHNEIDEWIND, Technische Universitat Munchen, TAEHWAN JANG, YOONHEE JEONG, Pohang University of Science and Technology, SANGWOOK CHEONG, Rutgers University — Evolution of static and dynamic spin correlations in a new multiferroics material $Sr_2FeSi_2O_7$ under an external magnetic field was investigated by elastic and inelastic neutron scattering techniques. An external magnetic field up to $B = 14$ Tesla induces four different magnetic and ferroelectric phases in $Sr_2FeSi_2O_7$. The static magneto-electric coupling can be understood as the p-d hybridization proposed for a related material $Ba_2CoGe_2O_7$. By analyzing the neutron scattering data obtained from a single crystal of $Sr_2FeSi_2O_7$ under magnetic field, we have determined the spin structure and the effective spin Hamiltonian in this material. The spin structure and spin wave excitations show interesting changes as upon ramping up the system enters the field-induced phases for $B > 6.5$ Tesla, which will also be discussed.

3:42PM C15.00007 Spin-lattice coupling and novel magnetic properties in the triangular lattice antiferromagnet Ag_2CrO_2 , MASAAKI MATSUDA, Quantum Condensed Matter Division, Oak Ridge National Laboratory — Spin-lattice coupling plays an important role in selecting the ground state in the geometrically frustrated magnets, since a small amount of structural distortion is sufficient to lift the ground state degeneracy and stabilize a long-range magnetic order. Ag_2CrO_2 consists of insulating triangular lattice planes of CrO_2 (Cr^{3+} ion with S=3/2), which are separated by the metallic Ag_2 layers. Interestingly, the electric transport in the Ag_2 layer is strongly affected by the magnetism in the CrO_2 layer. We performed neutron diffraction experiments on this material and found that a partially disordered state with 5 sublattices abruptly appears at $T_{\rm N}$=24 K, accompanied by a structural distortion [1]. The spin-lattice coupling stabilizes the anomalous state, which is expected to appear only in limited ranges of further-neighbor interactions and temperature. The nonnegligible further-neighbor interactions suggest the existence of the RKKY interaction mediated by the conduction electrons. We have recently performed inelastic neutron scattering experiments and found anomalous magnetic excitations, which cannot be explained simply by the linear spin-wave theory.

4:18PM C15.00008 The Dugganites: A new, frustrated, and potentially multiferroic class of compounds that exhibit rich magnetic behavior , HARLYN SILVERSTEIN, University of Manitoba, ARZOO SHARMA, AVICHAI STOLLER, KANISHA CRUZ-KAN, CHRISTOPHER WIEBE, University of Winnipeg — $Ba_3NbFe_3Si_2O_{14}$ is a multiferroic langasite (s.g. $P321$) wherein the Fe^{3+} atoms (S=5/2) occupy isolated trimers that stack along the c-axis. The spins uniquely order below T_N =26 K, where single domain helicity simultaneously exists with triangular chirality. Preparations of other langasites of this type are possible, so long as Fe^{3+} remains in the trimer site leaving the magnetism relatively unchanged. This is because Fe^{3+} occupies a tetrahedral site, where most other transition metal ions prefer the octahedral site occupied by Nb^{5+}. Building on previous research, we have circumvented this problem by replacing Nb^{5+} with Te^{6+}, which is found exclusively in octahedral coordination. Isostructural compounds $Pb_3TeCo_3A_2O_{14}$ (A=V^{5+}, P^{5+}) and $Pb_3TeMn_3P_2O_{14}$ (where the only magnetic ions are Co^{2+} and Mn^{2+} respectively) have been prepared and studied. Despite being isostructural to $Ba_3NbFe_3Si_2O_{14}$, the dugganites exhibit a rich variety of magnetic behavior, including evidence for multi-k magnetic structural arrangements, long-range coexistence of static and dynamic spins, and spin-spin interactions that potentially exist over 150 unit cells. In at least one dugganite, magnetoelectric coupling was observed at T_N entertaining the possibility that these compounds may also be multiferroic.

4:30PM C15.00009 Magnetic structure and excitations in $BaV_{10}O_{15}$, SACHITH DISSANAYAKE, JOOSEOP LEE, KAZUKI IIDA, University of Virginia, MATTHEW STONE, MASAAKI MATSUDA, Oak Ridge National Laboratory, TOMOMASA KAZITA, TAKURO KATSUFUJI, Waseda University, SEUNGHUN LEE, University of Virginia — Recently, new type of frustrated magnets, $BaV_{10}O_{15}$ and $SrV_{10}O_{15}$, were found to exhibit interesting physics due to the magnetic $V^{2.8+}$ ions with mixed valence. Using elastic and inelastic neutron scattering measurements we have examined the magnetic structure and excitations of $BaV_{10}O_{15}$. Magnetic excitations show highly dispersive two modes along c axis. Furthermore, two excitations are dispersionless along the a-axis. And very interestingly, along the b-axis one excitation is dispersionless while the other is strongly dispersive. Magnetic ground state of $BaV_{10}O_{15}$ was studied using neutron powder diffraction data, which order below 45 K with magnetic wave vector Q_m =(1/2 0 0). Here we present the possible magnetic structures of $BaV_{10}O_{15}$ using representation analysis, which can explain both the magnetic diffraction data and the basic features of the magnetic excitations observed in different directions. Linear spinwave calculations were also performed to shed light in understanding an effective spin hamiltonian for this system.

4:42PM C15.00010 Microscopic modeling of the 3D quantum magnet Cu_2OSeO_3 , OLEG JANSON, MPI CPfS, Dresden, Germany, IOANNIS ROUSOCHATZAKIS, ULRICH ROESSLER, JEROEN VAN DEN BRINK, IFW Dresden, Germany, ALEXANDER TSIRLIN, HELGE ROSNER, MPI CPfS, Dresden, Germany — Unlike most undoped cuprates, the $S = 1/2$ Heisenberg magnet Cu_2OSeO_3 exhibits a ferrimagnetic ground state and sizable magnetoelectric coupling. Recent experiments reported magnetic-field-induced emergence of skyrmions in this material. Based on extensive DFT band structure calculations we evaluate the microscopic magnetic model, including isotropic (Heisenberg) and anisotropic (Dzyaloshinskii-Moriya) terms. We extract five relevant couplings that form a complex, but non-frustrated spin model which can be described as a pyrochlore lattice of magnetic tetrahedra. A peculiar feature of this lattice is the alternation of "strong" (the constituent spins are strongly coupled) and "weak" tetrahedra. Profiting from a separation of the energy scales we develop an effective model, treating strong tetrahedra either as a classical $S = 1$ object or as a coherent quantum superposition of classical states. For the latter case, we find an excellent agreement with the quantum Monte Carlo simulations of the full model and the experimental magnetization and neutron diffraction data. Quite surprising for a 3D model we find distinct manifestations of quantum fluctuations. The developed effective model can be further used to model the field-induced behavior including the formation of skyrmions.

4:54PM C15.00011 Frustration by competing interactions in the highly-distorted double perovskites La_2NaRuO_6 and La_2NaOsO_6 , A.A. ACZEL, Quantum Condensed Matter Division, Oak Ridge National Laboratory, D.E. BUGARIS, Department of Chemistry and Biochemistry, University of South Carolina, L. LI, Department of Materials Science and Engineering, University of Tennessee, J.-Q. YAN, Department of Materials Science and Engineering, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, C. DE LA CRUZ, Quantum Condensed Matter Division, Oak Ridge National Laboratory, H.-C. ZUR LOYE, Department of Chemistry and Biochemistry, University of South Carolina, S.E. NAGLER, Quantum Condensed Matter Division, Oak Ridge National Laboratory — The usual classical behavior of S = 3/2, B-site ordered double perovskites results in simple, commensurate magnetic ground states. In contrast, heat capacity and neutron powder diffraction measurements for the S = 3/2 systems $La_2NaB'O_6$ (B' = Ru, Os) reveal an incommensurate magnetic ground state for La_2NaRuO_6 and a drastically suppressed ordered moment for La_2NaOsO_6. This behavior is attributed to the large monoclinic structural distortions of these double perovskites. The distortions have the effect of weakening the nearest neighbor superexchange interactions, presumably to an energy scale that is comparable to the next nearest neighbor superexchange. The exotic ground states in these materials can then arise from a competition between these two types of antiferromagnetic interactions, providing a novel mechanism for achieving frustration in the double perovskite family. Work at ORNL is supported by the Division of Scientific User Facilities and the Materials Science and Engineering Division, DOE Basic Energy Sciences. Work at the University of South Carolina is supported by the Heterogeneous Functional Materials Research Center, funded by DOE under award number de-sc0001061.

5:06PM C15.00012 Magnetostriction and magnetic texture to 100.75 Tesla in frustrated $SrCu_2(BO_3)_2$, M. JAIME, MPA-CMMS, LANL, Los Alamos, NM, USA, R. DAOU, MPI-CPfS, Dresden, Germany, S.A. CROOKER, F. WEICKERT, A. UCHIDA, MPA-CMMS, LANL, Los Alamos, NM, USA, A.E. FEIGUIN, Dep of Phys & Astr, Univ. of Wyoming, Laramie, WY , USA, C.D. BATISTA, Theory Div, LANL, Los Alamos, NM, USA, H.A. DABKOWSKA, Brockhouse Inst for Mat Res, McMaster Univ, Hamilton, ON, Canada, B.D. GAULIN, Dep of Phys & Astr, McMaster Univ, Hamilton, ON, Canada — $SrCu_2(BO_3)_2$, a spin-1/2 Heisenberg antiferromagnet in the archetypical Shastry-Sutherland lattice, exhibits a rich spectrum of magnetization plateaus and stripe-like magnetic textures in applied fields. The structure of these plateaus is still highly controversial due to the intrinsic complexity associated with frustration and competing length scales. We discover magnetic textures in $SrCu_2(BO_3)_2$ via FBG-optical fiber based magnetostriction and magnetocaloric measurements in fields up to 100.75 T. In addition to observing low-field fine structure with unprecedented resolution, the data also reveal lattice responses at 73.6 T and at 82 T that we attribute, using a controlled density matrix renormalization group approach, to a unanticipated 2/5 plateau and to the long-predicted 1/2 plateau. Research supported by NSF, State of Florida and the US DOE Basic Energy Science project "Science at 100T." ref: M. Jaime et al., $PNAS$ **109**, 120404 (2012).

5:18PM C15.00013 Antiferromagnetism, structural instability and frustration in intermetallic AFe_4X_2 systems[1] , HELGE ROSNER, CHRISTOPH BERGMANN, KATHARINA WEBER, INGA KRAFT, N. MUFTI, Max Planck Institute for Chemical Physics of Solids, Dresden, HANS-HENNING KLAUSS, T. DELLMANN, T. WOIKE, Dresden University of Technology, CHRISTOPH GEIBEL, Max Planck Institute for Chemical Physics of Solids, Dresden — Magnetic systems with reduced dimensionality or frustration attract strong interest because these features lead to an increase of quantum fluctuations and often result in unusual properties. Here, we present a detailed study of the magnetic, thermodynamic, and structural properties of the intermetallic AFe$_4$X$_2$ compounds (A=Sc,Y,Lu,Zr; X=Si,Ge) crystallizing in the ZrFe$_4$Si$_2$ structure type. Our results evidence that these compounds cover the whole regime from frustrated AFM order up to an AFM quantum critical point. Susceptibility χ(T), specific heat, resistivity, and T-dependent XRD measurements were performed on polycrystalline samples. In all compounds we observed a Curie-Weiss behavior in χ(T) at high T indicating a paramagnetic moment of about 3μ_B/Fe. Magnetic and structural transitions as previously reported for YFe$_4$Ge$_2$ occur in all compounds with trivalent A. However, transition temperatures, nature of the transition as well as the relation between structural and magnetic transitions change significantly with the A element. Low T_N's and large θ_{CW}/T_N ratios confirm the relevance of frustration. The results are analyzed and discussed with respect to electronic, structural and magnetic instabilities applying DFT calculations.

Session C16 GMAG DMP: Focus Session: Spin Dynamics and EPR 318 - Stephen Hill, Florida State University and NHMFL

2:30PM C16.00001 Synthesis and Physical Characterization of thin silicondioxide (SiO_2) layers with very high densities of E' centers , K. AMBAL, A. PAYNE, D.P. WATERS, C. WILLIAMS, C. BOEHME, Univ. of Utah — E' centers are paramagnetic (s=1/2) electronic states which are due to silicon dangling bonds in a-SiO_2 [1]. E' centers are able to trap electric charge, which can be detrimental to the performance of silicon based electronic devices. Therefore, most previous studies of E' centers have focused on a-SiO_2 layers with low E' center densities and material preparation techniques that allow to minimize it. Here, we present a study aiming at the opposite, the question of how E' center densities in a-SiO_2 can be maximized and whether E' centers in higher densities still exhibit similar spin dynamics (relaxation rates) in comparison to SiO_2 with low E' center densities. This study has been motivated by the need for a dielectric material containing very high spin densities as needed for single spin detection techniques. It is shown in this study that E' centers can be created at densities above $\sim 10^{19}$ cm^{-3} through exposure of a thin thermal oxide sample to an rf plasma containing Ar at low pressure. Most of the E' centers were found within 20 nm to 30 nm of the SiO_2 surface. While the high E' center densities can be annealed completely at 300 °C, they are very stable at room temperature. Spin relaxation time measurements show that T_2 of high density E' centers does not strongly depend on temperature and T_1 is $\sim$ 600μs at 5K with an increase towards lower densities [1]. At room temperatureT_1 is $\sim$ 160μs, which agrees well with values found in literature for E' centers at low densities [2].

2:42PM C16.00002 Towards force detected single electron spin resonance at room temperature

, C.C. WILLIAMS, A. PAYNE, K. AMBAL, C. BOEHME, University of Utah — Electrically detected magnetic resonance (EDMR) spectroscopy has shown that electron tunneling at or within silicon dioxide layers is strongly dependent on spin-selection rules [1]. Also demonstrated is the detection of single electron tunneling events by electrostatic force with sub-nanometer spatial resolution [2,3]. Here we propose to combine force detected single electron tunneling microscopy with EDMR to demonstrate a new kind of single spin force microscope. This approach has much better sensitivity than magnetic force based single spin microscopes [4], since electrostatic forces are much larger than corresponding magnetic forces. In this method, a paramagnetic state in an oxidized AFM probe tip is brought within tunneling range of a paramagnetic state in an oxide surface [5]. Under appropriate energy conditions, one of the unpaired electrons can randomly tunnel between the two states causing a random telegraph signal (RTS) to appear on the AFM cantilever frequency. Simulations predict that if magnetic resonance conditions are achieved, a measurable change in the RTS signal is detectable at room temperature. The theory and a quantitative simulation of this atomic scale spin resonance measurement will be presented, along with experimentally observed random telegraph signals.

2:54PM C16.00003 Local control of single-electron spin using spin-orbit coupling[1]

, MIGUEL ANGEL RODRIGUEZ-MORENO, Centro de Investigaciones en Semiconductores-ICUAP, LILIA MEZA-MONTES, Instituto de Fisica BUAP, DAVID HERNANDEZ DE LA LUZ, Centro de Investigaciones en Semiconductores-ICUAP — It has been demonstrated that CNOT quantum gates combined with single qubit operations form a universal set for quantum computing. In spin-based quantum qubits both conditions can be achieved by using a double quantum dot with two electrons. This configuration also allows for the realization of a completely electrical control of the spins, provided that hyperfine and spin-orbit interactions exist in the system. In this work, we simulate numerically the dynamics of the spin of two electrons in a double quantum dot. We use a combination of finite differences, direct diagonalization and a time propagator approach in order to solve the time-dependent two-electron Schrödinger equation. The single qubit operation is simulated by bringing the system into a separated charge state and then applying a time-varying electric field locally to one of the dots. It is shown that the spin-orbit coupling induces Rabi oscillations and that the frequency and amplitude of these oscillations can be varied by changing the magnitudes of the electric and static magnetic fields. We also analyze the role of the direction of the static magnetic field; in particular, we determine the variation of the spin dynamics with respect to direction of an in-plane static magnetic field.

3:06PM C16.00004 Analytical description of spin-Rabi oscillation controlled electronic transitions rates between weakly coupled pairs of paramagnetic states with S=(1/2)[1]

, RACHEL GLENN, WILLIAM BAKER, CHRISTOPH BOEHME, MIKHAIL RAIKH, University of Utah — We study theoretically and experimentally the Fourier content, $\mathbf{F}(s)$, of the Rabi oscillations in photoconductivity coming from pairs of spin-$\frac{1}{2}$ localized carriers. Upon increasing the ac drive, the Fourier spectrum evolves from a single peak at $s = \Omega_R$, where Ω_R is the Rabi frequency, to *three* peaks at $s = \Omega_R$, $s = 2\Omega_R$, and at low $s \ll \Omega_R$. The crossover between the two regimes takes place when Ω_R exceeds the broadening, δ_0, of Zeeman levels due to disorder, e.g., hyperfine field. We capture this crossover within the analytical treatment by calculating the shapes of all three peaks at arbitrary relation between Ω_R and δ_0. When the peaks are well-developed their widths are $\Delta s \sim \delta_0^2/\Omega_R$. Good agreement of theory and experiment allowed us to infer the experimental value of δ_0.

3:18PM C16.00005 The quantum to classical transition in atomic scale magnets

, FERNANDO DELGADO, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory (INL), Av. Mestre Jose Veiga, 4715-330 Braga, Portugal — Understanding the emergence of classical behavior in a world governed by quantum mechanics at the microscopic scale is one of the main fundamental open problems in physics. The radical differences between the two behaviors is dramatically represented by quantum systems that are, at the same time, in two classically different states. The quantum to classical transition is empirically linked to the size of the systems and conceptually related to the concept of environmental decoherence [1], but no general and clear rules have been determined. Here we consider it in the context of atomically engineered magnetic nanostructures [2,3] and we address fundamental questions such as the conditions under which a single adatom can behave classically or quantum mechanically. We show that the phase transition depends on the relative strength of its exchange coupling to surface and the renormalized zero-field splitting induced by quantum spin tunneling.

3:30PM C16.00006 Spin Fluctuation and Coherence in Concentrated systems[1]

, JOHAN VAN TOL, Florida State University, National High magnetic Field Laboratory, JINGFANG WANG, Florida State University, Department of Chemistry and Biochemistry, ZHENXING WANG, University of California at Los Angeles, Department of Electrical Engineering, SUSUMU TAKAHASHI, University of Southern California, Department of Chemistry — In materials with a relatively high density of electron spins without direct exchange pathways, the spin decoherence tends to be dominated by dipolar-interaction mediated spin-exchange/diffusion processes. These spin exchange processes will significantly be reduced at high magnetic fields and low temperatures when the spin polarization approaches the saturation limit. We will show some examples of single crystals of molecular magnetic complexes in which the decoherence is measured experimentally at high frequencies, and which form a reference for direct theoretical models that predict the spin decoherence in these systems, and their dependence on orientation, temperature and field.

[1]The National High Magnetic Field is sponsored by the NSF and the State of Florida

3:42PM C16.00007 High Field Electron Paramagnetic Resonance (HFEPR) study on a Mn(IV) monomer

, ASMA AMJAD, ENRIQUE DEL BARCO, University of Central Florida, STEPHEN HILL, Florida State University and National High Magnetic Field Laboratory, Tallahassee, JOHAN VAN TOL, ANDRZEJ OZAROWSKI, National High Magnetic Field Laboratory, Florida State University, Tallahassee, MAHAMMAD ALI, Jadavpur University — In this work we investigated the magnetic anisotropy of a Mn (IV) monomer via axial and rhombic zero field splitting terms D, E. The d^3 ion sits in an octahedral environment in a P 21/c space group. The complex is studied via single crystal and powder HFEPR over a wide range of frequencies 49GHz to 416GHz and temperatures 2 to 60K. The angle dependence at low temperature and frequency (∼88GHz) reveals a minimum of the resonance field, when the long axis of the crystal is along the magnetic field. The same behavior is observed at higher frequency (∼240GHz). Furthermore, pulse EPR experiments in high frequency quasi-optical spectrometer at low temperature (∼1.487K) a spin echo could be observed and we were able to observe the variation of the T_2 times as a function of the magnetic field orientation, and as a function of the temperature.

3:54PM C16.00008 Cavity Perturbation Technique: The Effects of Crystal Size on the EPR Spectra of Fe_8 Single-molecule Magnets[1] , MUHANDIS SHIDDIQ, Dept. of Physics and NHMFL, Florida State University, Tallahassee, FL 32310, USA, CHRISTOPHER C. BEEDLE, NHMFL, Florida State University, Tallahassee, FL 32310, USA, STEPHEN HILL, Dept. of Physics and NHMFL, Florida State University, Tallahassee, FL 32310, USA — The Cavity Perturbation Technique (CPT) is a contact-free technique that measures the change of the characteristics of a cavity resonator upon the introduction of the sample. In this experiment, we study the effect of crystal size with regards to the CPT transmission spectra for a single crystal of the Fe_8 single-molecule magnets. It is interesting to study the interaction between these two resonance systems, i. e. a cavity and a crystal of Fe8. We want to know whether it is a quantum mechanical or a classical interaction. The frequency shift and suppression of the cavity Q value increase linearly with increasing sample size. These observations are in agreement with the theoretical expectation for a classical coupling between the Fe_8 crystal and the cavity. From cavity perturbation theory, these phenomena may be explained by the following classical formula: $\Delta\omega/\omega = -\beta\chi$, where ω is the complex frequency, β is the filling factor that depends on the sample volume and the resonant mode of the cavity, and χ is the complex susceptibility.

4:06PM C16.00009 Single molecule magnets from magnetic building blocks , W. KROENER, Lehrstuhl für Experimentalphysik, Universität Erlangen, Germany, A. PARETZKI, C. CERVETTI, 1. Physikalisches Institut, Universität Stuttgart, Germany, S. HOHLOCH, Institut für Anorganische Chemie, Universität Stuttgart, Germany, S. RAUSCHENBACH, K. KERN, Max Planck Institut für Festkörperforschung, Stuttgart, Germany, M. DRESSEL, L. BOGANI, 1. Physikalisches Institut, Universität Stuttgart, Germany, P. MÜLLER, Lehrstuhl für Experimentalphysik, Universität Erlangen, Germany — We provide a basic set of magnetic building blocks that can be rationally assembled, similar to magnetic LEGO bricks, in order to create a huge variety of magnetic behavior. Using rare-earth centers and multipyridine ligands, fine-tuning of intra and intermolecular exchange interaction is demonstrated. We have investigated a series of molecules with monomeric, dimeric and trimeric lanthanide centers using SQUID susceptometry and Hall bar magnetometry. A home-made micro-Hall-probe magnetometer was used to measure magnetic hysteresis loops at mK temperatures and fields up to 17 T. All compounds show hysteresis below blocking temperatures of 3 to 4 K. The correlation of the assembly of the building blocks with the magnetic properties will be discussed.

4:18PM C16.00010 Theoretical calculations of spin dynamics and quantum effects in rare earth SMMs , ALEJANDRO GAITA-ARIÑO, Instituto de Ciencia Molecular, University of Valencia — Rare-earth single-molecular magnets constitute a hot emerging topic in molecular magnetism. It also constitutes a promising field to study and eventually remedy the processes that lead to decoherence. In fact, experiments show some success in the design of rare-earth spin qubits with long coherence times. Furthermore, these long-lived quantum states of rare-earth SMMs can in principle be manipulated for quantum information processing. In particular, a simple quantum error correction protocol might be realizable using ElectroNuclear DOuble Resonance. Going further on this path will require a detailed knowledge of the wave function of the low-energy multiplet, and an understanding of how it can be tailored by chemical means. An inexpensive point-charge model has been presented recently that is able to reproduce the main features of the Crystal Field Hamiltonian of both lanthanoids (such as Dysprosium, Holmium, Terbium) and actinoids such as Uranium.

4:54PM C16.00011 Probing magnetic interactions in molecule-based materials using high-pressure electron paramagnetic resonance , K. THIRUNAVUKKUARASU, National High Magnetic Field Laboratory (NHMFL), Tallahassee, Florida, USA, C.C. BEEDLE, NHMFL, Tallahassee, Florida, USA, S. WINTER, Department of Chemistry, University of Waterloo, Ontario, Canada, A. KOVALEV, S. TOZER, NHMFL, Tallahassee, Florida, USA, R.A. OAKLEY, Department of Chemistry, University of Waterloo, Ontario, Canada, S. HILL, NHMFL and Department of Physics, Florida State University, Tallahassee, Florida, USA — Multi-frequency electron paramagnetic resonance (EPR) spectroscopy is a powerful technique for investigating magnetic exchange interactions in quantum matter. EPR spectroscopy when combined with techniques such as high pressure will enable us to probe various quantum phase transitions that give rise to novel electronic and magnetic phases in correlated electron systems. However, this particular combination of experimental tools has remained uncommon for several decades. Recently, our group has successfully implemented high pressure technique together with EPR spectroscopy. Cavity-based high-frequency EPR measurements can now be performed in the frequency range from 40 GHz to 200 GHz at temperatures down to 1.6 K under quasi-hydrostatic pressures up to 30 kbar. With the application of pressure, the inter-atomic/molecular correlations can be tuned continuously to reveal the nature of magnetic anisotropy and exchange interaction. In this talk, the realization of high pressure EPR spectroscopy will be briefly described using one of the molecule-based materials such as single-molecule magnet, organic radical-based ferromagnet etc., as an example.

5:06PM C16.00012 Magnetoelectric coupling in 4, 4'-stilbenedinitrene[1] , J.L. MUSFELDT, O. GUNAYDINSEN, P. CHEN, J. FOSSO-TANDE, University of Tennessee, T. ALLEN, University of Massachusetts, J. CHERIAN, T. TOKUMOTO, S. MCGILL, National High Magnetic Field Laboratory, P.M. LAHTI, University of Massachusetts, R.J. HARRISON, University of Tennessee — We investigated the optical properties of 4,4′-stilbenedinitrene at low temperature and in high magnetic fields and compared the results with complementary first principles calculations. Both physical tuning parameters allow us to manipulate the singlet-triplet equilibrium, and by so doing, control the optical contrast (which is on the order of -2.5×10^2 cm^{-1} at 555 nm and 35 T). Moreover, analysis of the magneto-optical response using a combined population and Beer's law framework reveals the singlet-triplet spin gap and identifies particular features in the absorption difference spectrum as deriving from singlet or triplet state excitations. These findings deepen our understanding of coupling in open shell molecules and show how highlight opportunities where chemical structure modification can amplify charge-spin interactions in organic biradicals.

5:18PM C16.00013 Effective model and spin/charge ordering in molecular conductors $X[Pd(dmit)_2]_2$, HITOSHI SEO, RIKEN/JST-CREST, TAKAO TSUMURAYA, RIKEN/National Institute for Materials Science, MASAHISA TSUCHIIZU, Nagoya University, TSUYOSHI MIYAZAKI, National Institute for Materials Science, REIZO KATO, RIKEN — The family of molecular conductors, β'-type $X[Pd(dmit)_2]_2$ (X: monovalent cation) salts, show a variety of electronic states: dimer-type Mott insulator, magnetic order, spin-liquid behavior, metallic/superconducting states, and a peculiar charge ordering involving multi-orbitals[1]. In this work, we construct an effective low-energy model which takes into account the multi-orbital degree of freedom. We consider fragments of molecular orbital as a basis set, nearly localized on either one of the dmit ligands. The transfer integrals are obtained for a series of salts by fitting to the first-principles band calculations[2]. We find that all the intra-dimer transfer integrals including the diagonal ones are of the same order; this results in a modification of the orbital scheme in strongly dimerized $[Pd(dmit)_2]_2$ discussed in the literatures, then to the effective one-band model. We calculate possible spin and charge ordering based on mean-field approximation to the extended Hubbard model incorporating the fitted parameters. [1] R. Kato, Chem. Rev. 104 (2004) 5319; K. Kanoda and R. Kato, Annu. Rev. Condens. Matter Phys. 2 (2011) 167. [2] T. Miyazaki and T. Ohno, Phys. Rev. B 59 (1999) 5269; T. Tsumuraya, H. Seo, M. Tsuchiizu, R. Kato, and T. Miyazaki, in preparation.

Session C17 GMAG: Magnetic Theory I 319 - Marcu Eisenbach, Oak Ridge National Laboratory

2:30PM C17.00001 First principles calculation of finite temperature magnetism in Ni , MARKUS EISENBACH, JUNQI YIN, DON M. NICHOLSON, YING WAI LI, Oak Ridge National Laboratory — We harnesses the computational power of massively parallel computers to calculate finite temperature magnetic properties by combining classical Monte-Carlo calculations with our first principles multiple scattering electronic structure code (LSMS) for constrained magnetic states. Our previous calculations of Fe and Fe_3C [J. Appl. Phys. 109, 07E138 (2011)] only considered fluctuations in the local moment directions. Recent advances, both in the understanding of the Wang-Landau method used in our calculations [Phys. Rev. E 84, 065702(R) (2011)] and more powerful computing resources have enabled us to investigate Ni where the fluctuation in the magnitude of the local magnetic moments is of importance equal to their directional fluctuations. Here we will present our recent results for Ni that axpands our method to an even wider class of 3d element based ferromagnets. This research was sponsored by the Offices of Basic Energy Science (M.E. and D.M.N) and the Office of Advanced Computing Research (J.Y. and Y.W.L) of the US Department of Energy. This research used resources of the Oak Ridge Leadership Computing Facility at Oak Ridge National Laboratory, which is supported by the Office of Science of the Department of Energy under contract DE-AC05-00OR22725.

2:42PM C17.00002 Sheared Ising models in three dimensions[1] , ALFRED HUCHT, SEBASTIAN ANGST, Faculty of Physics, University of Duisburg-Essen, 47048 Duisburg, Germany — The nonequilibrium phase transition in sheared three-dimensional Ising models is investigated using Monte Carlo simulations in two different geometries corresponding to different shear normals [A. Hucht and S. Angst, EPL 100, 20003 (2012)]. We demonstrate that in the high shear limit both systems undergo a strongly anisotropic phase transition at exactly known critical temperatures T_c which depend on the direction of the shear normal. Using dimensional analysis, we determine the anisotropy exponent $\theta = 2$ as well as the correlation length exponents $\nu_{\parallel} = 1$ and $\nu_{\perp} = 1/2$. These results are verified by simulations, though considerable corrections to scaling are found. The correlation functions perpendicular to the shear direction can be calculated exactly and show Ornstein-Zernike behavior.

2:54PM C17.00003 Heat capacity and new classification of phase transitions of fractional order: Ising model[1] , VLADIMIR UDODOV, Katanov Khakas State University, KATANOV KHAKAS STATE UNIVERSITY TEAM — Though the one-dimensional Ising model has been the subject of a wide variety of analysis, it remains one of significant interest. Here we show that within the framework of Gibbs distribution this model can undergo fractional and arbitrarily high order phase transitions (PT) as the temperature changes at zero magnetic field. We suggest a new formula to define the order of PT for a special case of $T_c = 0$; it is expressed via the critical exponent α associated with the heat capacity C. The unusual values of α (for example, $\alpha < -10$) are predicted. An interesting transition from 2D to 1D Ising model is considered. It corresponds the situations when the inter-particle interaction is gradually switched off along one of two dimensions. As the system approaches the 1D limit, the critical temperature T_c tends to zero during which the critical exponent α changes continuously . The general formula for an order of PT offered extending formula R. Baxter and it is correct as for $T_C > 0$ and $T_C = 0$. The developed approach is equally applicable to quantum phase transitions.

3:06PM C17.00004 Finite-size scaling behavior of the magnetization distribution for 5d Ising model , P. H. LUNDOW, A. ROSENGREN, KTH (Royal Institute of Technology) — We have previously established that the magnetization distribution of the 5-dimensional Ising model can be fitted by a p, q-binomial distribution. Our extensive sampled Monte Carlo data can be used to determine the parameters' finite-size behavior. Now we use a long series expansion of the p, q-binomial coefficients to obtain finite-size scaling formulas not only for the Binder ratio and the susceptibility near T_c, but also for the entire magnetization distribution, including corrections-to-scaling terms.

3:18PM C17.00005 E8 spectrum and the finite temperature spin dynamics in the transverse field Ising chain with a small longitudinal field , JIANDA WU, Rice University, MARTON KORMOS, Dipartimento di Fisica dell'Universit a di Pisa and INFN, Pisa, Italy, QIMIAO SI, Rice University — When the transverse field Ising chain at its quantum critical point is subjected to a small longitudinal field, the perturbed conformal field theory led to a field theory with an exotic E8 symmetry [1]. Recent neutron scattering experiments have provided evidence for the lightest two particles in this E8 model in the quasi-1D Ising ferromagnet CoNb2O6 [2]. While the zero temperature dynamics of the model is well known, its finite-temperature counterpart has not yet been systematically studied. We study the low-frequency dynamical structure factor at finite temperatures using the form-factor method. We show that the dominant contribution to the dynamical structure factor comes from the scattering between two lightest particles, and discuss the implications of our results for the NMR relaxation rate. 3:54PM C17.00008 Critical Point Estimation and Long-Range Behavior in the One-Dimensional XY Model Using Thermal Quantum and Total Correlations[1] , BARIS CAKMAK, GOKTUG KARPAT, ZAFER GEDIK, Faculty of Engineering and Natural Sciences, Sabanci University — We investigate the thermal quantum and total correlations in the anisotropic XY spin chain in transverse field. While we adopt concurrence and geometric quantum discord to measure quantum correlations, we use measurement-induced nonlocality and an alternative quantity defined in terms of Wigner-Yanase information to quantify total correlations. We show that the ability of these measures to estimate the critical point at finite temperature strongly depend on the anisotropy parameter of the Hamiltonian. We also identify a correlation measure which detects the factorized ground state in this model. Furthermore, we study the effect of temperature on long-range correlations.

4:06PM C17.00009 General method for finding ground state manifold of classical Heisenberg model[1] , ZHAOXI XIONG, Massachusetts Institute of Technology, XIAO-GANG WEN, Massachusetts Institute of Technology and Perimeter Institute — What is the ground state manifold of a classical Heisenberg model for an infinite crystal? It sounds simple, but the intuitive approach gets stuck for more general interaction patterns and higher crystal dimensions. In this paper we present an essentially analytical method that can deal with all systems with one-spin unit cells and a broad class of systems with multi-spin unit cells. We also prove a theorem that guarantees that these systems must have some "spiral ground states," which are co-planar. The method can be applied to classify all such systems, so that one can read off the ground state manifold of a Hamiltonian from some of its "spectral properties." It can also be generalized to XY models, finite crystals, and anisotropic couplings, and may be helpful for quantum anomalous Hall effect and spin liquids.

[1]Supported by NSF-DMR and NSFC.

4:18PM C17.00010 Invariant correlation entropy as a signature of quantum phase transitions in spin-1/2 systems[1] , DAVIDA KOLLMAR, LEA SANTOS, Yeshiva University — The invariant correlation entropy was introduced in the context of nuclear physics as a way to quantify the degree of complexity of quantum states. Contrary to the Shannon information entropy or the inverse participation ratio, this entropy is basis independent. We show that it peaks in critical regions and can therefore be used to signal quantum phase transitions. Our findings are based on the numerical analysis of one-dimensional spin-1/2 systems described by different Heisenberg models and by the anisotropic XY model in a transverse magnetic field.

4:30PM C17.00011 The Integrable Chiral Potts Model: Quantum Group Methods Applied to Superintegrable Case[1] , JACQUES H.H. PERK, HELEN AU-YANG, Department of Physics, Oklahoma State University — The integrable chiral Potts model resulted in the 1980s from a search of new solutions of the star-triangle (Yang–Baxter) equations for spin models with expected parafermionic excitations. Its structure relates to cyclic representations of quantum groups at roots of unity, while the so-called superintegrable subcase has additional Onsager algebra structure. Recently the authors have utilized this quantum algebraic information, to derive detailed explicit results for the eigenvectors in the ground state sectors and give new information for the eigenvectors in general. One result is the explicit derivation of the spontaneous magnetization without hidden assumptions, as both conjectures made earlier have now been proved. The explicit eigenvectors also lead to some results for correlation functions. We shall present a review of what has been done so far and discuss the current status of the research.

4:42PM C17.00012 Accounting for spin fluctuations beyond LSDA in the density functional theory[1] , LUCIANO ORTENZI, Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany, IGOR I. MAZIN, Naval Research Laboratory, 4555 Overlook Avenue SW, Washington, D.C. 20375, USA, PETER BLAHA, Institute of Materials Chemistry, Vienna University of Technology, Getreidemarkt 9/165-TC, A-1060 Vienna, Austria, LILIA BOERI, Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — We present a method to correct the magnetic properties of itinerant systems in local spin density approximation (LSDA) and we apply it to the ferromagnetic-paramagnetic transition under pressure in a typical itinerant system, Ni_3Al. We obtain a scaling of the critical fluctuations as a function of pressure equivalent to the one obtained within Moryia's theory. Moreover we show that in this material the role of the bandstructure is crucial in driving the transition. Finally we calculate the magnetic moment as a function of pressure, and find that it gives a scaling of the Curie temperature that is in good agreement with the experiment. The method can be easily extended to the antiferromagnetic case and applied, for instance, to the Fe-pnictides in order to correct the LSDA magnetic moment.

4:54PM C17.00013 First-principles investigation of deviations from Matthiessen's rule due to the interplay of phonon and spin disorder scattering in iron and gadolinium , JAMES GLASBRENNER, KIRILL BELASHCHENKO, University of Nebraska - Lincoln — Magnetic materials contain an anomalous contribution to the electrical resistivity due to thermal spin fluctuations, which saturates in the disordered phase and is called the spin-disorder resistivity (SDR). Experimental determination of the SDR involves fitting to high-temperature resistivity data and extrapolating to T=0 K. Recent calculations of the SDR of the heavy rare-earth metals revealed strong underestimations of this quantity, particularly for Gd, while the results for transition metals were in good agreement with experiments. In order to understand this discrepancy, here we evaluate the mutual effects of phonon and spin-disorder scattering in Fe and Gd. Calculations are performed using the supercell approach within the linear muffin-tin orbital method. The atomic positions are displaced according to the Gaussian distribution, and the resistivity is evaluated as a function of the mean-square displacement $\Delta^2 \propto T$. The deviations from Matthiessen's rule (DMR) are large in Gd and moderate in Fe. Fitting the linear region of ρ vs Δ^2 in Gd yields an intercept ~ 2.5 times larger than the "bare" SDR, significantly improving the agreement with experiment. Large DMR suggest large variations of the relaxation time on the anisotropic Fermi surface.

5:06PM C17.00014 Quantum torus chain , MINGPU QIN, Institute of Physics, Chinese Academy of Sciences, JON MAGNE LEINAAS, Department of Physics, University of Oslo, SHINSEI RYU, Department of Physics, University of Illinois at Urbana-Champaign, EDDY ARDONNE, Nordita, Royal Institute of Technology and Stockholm University, TAO XIANG, Institute of Physics, Chinese Academy of Sciences and Institute of Theoretical Physics, Chinese Academy of Sciences, DUNG-HAI LEE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — We introduce a set of one-dimensional quantum lattice models which we refer to as the quantum torus chain. These models have discrete global symmetry and projective on-site representations. They possess an integer-valued parameter which controls the presence or absence of frustration. Depending on whether this parameter is even or odd, these models exhibit either gapped symmetry-breaking phases with isolated critical points or gapped symmetry-breaking phases separated by gapless phases.We discuss the property of these phases and phase transitions for two special values of the parameter and point out many open problems.

5:18PM C17.00015 Exchange and Magnetic Anisotropic Interactions of Magnetic Ions in Antiferromagnetic Materials , ALEXANDER BAZHAN, P.L.Kapitza Institute for Physical Problems, RAS, Moscow, Russia — Investigations of antiferromagnetic orderings, based on theory of crystallographic and magnetic symmetry, which indicates quadratic forms of thermodynamic potentials, invariated with respect to operations of magnetic symmetry groups and presented in irreducible representations of magnetic moments, are caring out, using vector magnetometer, introducing $\chi{\cdot}(1{-}\chi_{//}\,(\mathbf{l}_i^2)/\chi){\cdot}(\,\gamma_i\mathbf{H})^2$ terms in discussions. Magnetic field dependencies of samples three magnetic moments components directly indicate magnetic ions interactions. Symmetric, Anderson, and antisymmetric, Dzyaloshinskii-Moria, exchange interactions in antiferromagnetic orderings, in rhombohedral structures, as example, $H_{ex} = \sum_{i,j} J_{i,j}{\cdot}(\mathbf{S}_i\mathbf{S}_j) - \sum_{i,j} D_{i,j,z}{\cdot}(\mathbf{S}_{i,x}\mathbf{S}_{j,y}{-}\mathbf{S}_{i,y}\mathbf{S}_{j,x})$, determine weak ferromagnetic states at selected orientations of antiferromagnetic vectors. Weak ferromagnetic states, of second and higher orders interactions of magnetic ions, are presented in the report.

Session C18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Spin Injection and Transport 320 - Paul Crawell, University of Minnesota

2:30PM C18.00001 Optical spin injection into Ge at room temperature , YUHSUKE YASUTAKE, SHUHEI HAYASHI, SUSUMU FUKATSU, Graduate School of Arts and Sciences, The University of Tokyo — A realistic opto-spintronic device draws on the knowledge and control over the optical orientation at room temperature. We investigated circularly polarized photoluminescence of tensilely strained Ge-on-Si in an attempt to inject spins into Ge by optical means at ambient temperature. More than 10-% polarization was observed up to 300 K. The absence of indirect-gap luminescence facilitated spectral analysis. Meanwhile, very fast decay was observed, unlike bulk Ge with little spin polarization. This indicates that intervalley scattering has diminished in Ge-on-Si due presumably to dissipative channels introduced during growth. It is concluded that spin coherence remains in a short time scale. This led us to optical injection of spins, O(1%), in bulk Ge at room temperature, which was observed in the prompt decay.

2:42PM C18.00002 Spin accumulation in Ge at room temperature , A.T. HANBICKI, S.-F. CHENG, R. GOSWAMI, O.M.J. VAN 'T ERVE, B.T. JONKER, Naval Research Laboratory — We have investigated spin injection into n-type Ge(001) from Fe through a sputter-deposited MgO tunnel barrier using 3-terminal Hanle measurements[1]. Unlike Si, spin research in Ge is hampered by Fermi level pinning at the Ge interface, which makes it difficult to efficiently inject carriers. We observe here precessional dephasing of the spin accumulation in an applied B-field (Hanle effect) in Fe/MgO/Ge for both forward and reverse bias. At room temperature, spin lifetimes range from $\tau_s = 50$ ps to 123 ps as the carrier concentration is reduced from n=8x10^{17}cm^{-3} to 2x10^{16}cm^{-3}. The measured spin resistance-area product is in good agreement with values predicted by theory for samples with carrier densities below the metal-insulator transition (MIT), but 100x larger for samples above the MIT. These data demonstrate that measured spin accumulation occurs in the Ge, although dopant-derived interface or band states may enhance the measured spin voltage above the MIT. The observed room temperature injection of spins shows that despite persistent Fermi level pinning, spin accumulation is possible in the surface region of Ge. This work was supported by core programs at NRL.
[1] A.T. Hanbicki, et al., $SolidStateComm.$ **152**, 244 (2012).

2:54PM C18.00003 Crossover from Spin Accumulation into Interface States to Spin Injection in the Germanium Conduction Band , JUAN-CARLOS ROJAS-SANCHEZ, ABHINAV JAIN, MURAT CUBUKCU, INAC/SP2M, CEA and Université Joseph Fourier, JULIAN PEIRO, JEAN-CHRISTOPHE LE BRETON, CNRS-Thalès and Université Paris XI, ERIC PRESTAT, CÉLINE VERGNAUD, PASCALE BAYLE-GUILLEMAUD, LAURENT VILA, JEAN-PHILIPPE ATTANÉ, INAC/SP2M, CEA and Université Joseph Fourier, EMMANUEL AUGENDRE, LETI Minatec Campus, CEA, SERGE GAMBARELLI, INAC/SCIB, CEA and Université Joseph Fourier, HENRI JAFFRÈS, JEAN-MARIE GEORGE, CNRS-Thalès and Université Paris XI, MATTHIEU JAMET, INAC/SP2M, CEA and Université Joseph Fourier — Spin injection into semiconductors is crucial for exploring spin physics and new spintronic devices. Ge is of great interest for high carrier mobilities, long spin diffusion length and large spin-orbit coupling to perform electric field spin manipulation. However the exact role of interface states in spin injection mechanism in n-Ge has not been clarified yet. Here we show a clear transition from spin accumulation into interface states to spin injection in the Ge conduction band. For this purpose, we have grown CoFeB/MgO as a spin injector on Germanium On Insulator. We observe spin signal amplification at low temperature due to spin accumulation into interface states. At 150 K, we find a clear transition to spin injection in the conduction band up to room temperature: the measured spin signal is compatible with the spin diffusion model. We could in particular demonstrate spin signal modulation applying a back gate voltage and spin-pumping by the ferromagnetic resonance of the CoFeB layer which are clear manifestations of spin accumulation in the Ge conduction band.

3:06PM C18.00004 Electrical Spin Injection and Detection in Silicon Nanowires , SHIXIONG ZHANG, SHADI DAYEH, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, YAN LI, SCOTT A. CROOKER, National High Magnetic Field Laboratory, Los Alamos National Laboratory, DARRYL L. SMITH, Theoretical Division, Los Alamos National Laboratory, S. T. PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — We report on the electrical injection and detection of spin-polarized electrons from cobalt contacts into n-type Si nanowires through Al2O3 tunneling barriers. Analysis of local (2 terminal) and non-local (4 terminal) spin valve signals at 4 K on the same nanowire device using a standard spin-transport model suggests that high spin injection efficiency (about 30%) and long spin diffusion lengths (about 6 micron) are achieved for these nanoscale structures. These values compare favorably to those reported for spin transport devices based on comparably-doped bulk Si. The spin valve signals are strongly influenced by temperature, bias current and by the geometry of the ferromagnetic

3:18PM C18.00005 Electrical spin injection into Si with Ni/graphene contacts , CONNIE H. LI, OLAF M. J. VAN 'T ERVE, JEREMY T. ROBINSON, BERRY T. JONKER, Naval Research Lab — Graphene, a single layer of sp2 bonded C atom, provides a highly uniform barrier with well-controlled thickness and minimal defect, has been shown to be a viable tunnel barrier in magnetic tunnel junctions [1]. More recently, we have further demonstrated that it also circumvents the conductivity mismatch between a FM metal and semiconductor, whilst lowering the resistance area product [2]. Excellent spin filtering has also been predicted across graphene-magnetic metal (e.g., Ni, Co) interfaces, due to electronic structure overlap for only the minority spin [3]. This spin filtering effect is also accumulative, with predicted spin polarization reaching 100% with multiple layers (>5) of graphene, and is also robust against interface roughness and disorder [3]. Here we explore electrical spin injection into Si utilizing this spin filtering effect in a Ni/graphene/Si structure. We observe Hanle precession of the electron spin accumulation in the semiconductor, where the extracted spin lifetime from the Lorentzian fit to the Hanle data, $\sim$ 160 ps, is consistent with those observed for this Si carrier density (1E19) with other FM contacts (NiFe) and tunnel barriers (SiO2, Al2O3, graphene) [2,4], confirming spin injection and accumulation in the Si. Results comparing single and multiple layer graphene tunnel barriers will also be presented.

3:30PM C18.00006 A graphene solution to conductivity mismatch: spin injection into Silicon , OLAF VAN 'T ERVE, ADAM FRIEDMAN, ENRIQUE COBAS, CONNIE LI, AUBREY HANBICKI, KATHY MCCREARY, JEREMY ROBINSON, BEREND JONKER, Naval Research Laboratory — The classic FM/semiconductor conductivity mismatch prevents spin injection into silicon. Typically, an oxide barrier such as MgO, AlOx or SiO2 is used to overcome this mismatch. These oxide tunnel barriers introduce defects, trapped charge, interdiffusion and add significant resistance, which compromise device performance. Here we will show that a FM/graphene contact serves as a spin-polarized tunnel barrier. [1] Although graphene is very conductive in plane, it exhibits poor conductivity perpendicular to the plane. Its sp2 bonding results in a highly uniform, defect free layer, which is chemically inert, thermally robust, and impervious to diffusion. The use of a monolayer of graphene at the Si interface provides a much lower RA product than any oxide film thick enough to prevent pinholes. We will present electrical injection and detection of spin accumulation in Si above room temperature, and show that the corresponding spin lifetimes correlate with the Si carrier concentration. The RA products are three orders of magnitude lower than achieved with oxide tunnel barrier contacts on identical Si substrates. Our results identify a new route to low RA-product spin-polarized contacts, a crucial requirement enabling future semiconductor spintronic devices, which rely upon two-terminal MR. 3:42PM C18.00007 Analysis of 3-terminal Hanle signals in Si-based spintronic devices , SHOICHI SATO, RYOSHO NAKANE, MASAAKI TANAKA, Dept. of Electrical Engineering and Information Systems, The University of Tokyo — We have investigated 3-terminal Hanle (3TH) signals and inverted 3-terminal Hanle (Inv3TH) signals [1] obtained in a temperature range of 5 – 300 K in devices with a Si channel and Fe/SiO_2/Si tunnel junctions. The Hanle signals were measured with a magnetic field applied in various directions from parallel (Inv3TH) to normal (3TH) to the plane. The shape of the 3TH signals was a positive Lorentzian, whereas that of the Inv3TH signals was composed of two negative Lorentzians whose centers are at around $\pm$ 1000 Oe. We analyzed the signals using the Eq.(2) in [1], in which the effective magnetic field acting on electron spins is assume to be composed of the following fields; an applied field, a constant stray field, and a stray field proportional to the magnetization of the Fe electrode. Note that the last two fields are introduced in the present analysis. All the experimental signals in any applied field directions were well fitted by the formula. From the fitting parameters at various measurement temperatures, we found that the FWHM of the 3TH signals is determined by the stray field of the Fe electrode, and that the spin-polarized electrons accumulate in electronic states between the Fe electrode and the Si channel.

3:54PM C18.00008 Correlation of electrical spin injection and non-linear charge-transport in Fe/MgO/Si[1] , JONAS BEARDSLEY, YONG PU, Dept. of Physics, The Ohio State University, PATRICK ODENTHAL, ADRIAN SWARTZ, ROLAND KAWAKAMI, Dept. of Physics, University of California, Riverside, P. CHRISTOPHER HAMMEL, EZEKIEL JOHNSTON-HALPERIN, Dept. of Physics, The Ohio State University, JAIRO SINOVA, Dept. of Physics, Texas A&M University, JON PELZ, Dept. of Physics, The Ohio State University — The three-terminal (3T) Hanle method has recently been used by several groups to measure electrical spin injection into Si up to 500K, with signals that can be orders of magnitude larger than expected for spin injection into bulk Si states. While much discussion has centered on the possible origin of the enhanced spin signal, there has been little discussion of the anomalously-strong bias dependence of the spin resistance area product (SRA) often measured at low-temperatures. We report 3T-Hanle measurements MBE grown Fe/MgO/Si tunnel diodes which show an SRA up to seven orders larger at low temperature than the bulk prediction, which is both strongly bias dependent and highly correlated with the differential resistance area product, dV/dJ, over a large range of bias and temperature. This cannot be explained by current theories that assume energy-independent tunneling into localized or bulk states. We show that a simple model with strongly energy-dependent tunneling can explain the strong bias-dependences and correlation of the SRA and dV/dJ, and suggests that the intrinsic spin-injection properties may have little bias dependence even though the measured SRA decreases by three orders of magnitude with increasing bias.

4:06PM C18.00009 Spin filtering with EuO: Insight from a complex band structure , PAVEL LUKASHEV, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, ALEKSANDER WYSOCKI, School of Applied Engineering Physics, Cornell University, JULIAN VELEV, Department of Physics, Institute for Functional Nanomaterials, University of Puerto Rico, MARK VAN SCHILFGAARDE, Department of Physics, Kings College London, England, UK, SITARAM JASWAL, KIRILL BELASHCHENKO, EVGENY TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln — Spin-filter tunneling is a promising way to create highly-spin-polarized currents. So far the understanding of the spin-filtering effect has been limited to a free-electron description based on the spin-dependent tunneling barrier height. In this work we employ density-functional calculations to explore the complex bands of EuO as a representative ferromagnetic insulator used in spin-filter tunneling experiments and show that the mechanism of spin filtering deviates significantly from the standard free-electron picture and involves effects associated with the symmetry of spin-dependent evanescent states and the dependence of the decay constant on the transverse wave vector. We demonstrate the importance of the multiorbital band structure with an indirect band gap for spin-filter tunneling. By analyzing the symmetry of the complex bands and the decay rates for different wave vectors and energies we draw conclusions about spin-filter efficiency of EuO. Our results provide a new insight into spin-filter tunneling and may help to design tunnel junctions with enhanced spin polarization.

4:18PM C18.00010 Doping dependence of the inverse spin-Hall effect in n-GaAs near the metal-insulator transition , CHAD GEPPERT, KEVIN CHRISTIE, MUN CHAN, University of Minnesota, SAHIL PATEL, CHRIS PALMSTRØM, University of California, Santa Barbara, PAUL CROWELL, University of Minnesota — We present measurements of the inverse spin-Hall effect in n-GaAs at various doping levels ranging from one to five times the Mott criterion ($n_c \approx 2\times10^{16}$/cm^3). Spin currents are generated electrically (from either Fe or Co_2MnSi) which give rise to a Hanle effect in the local Hall voltage. The observed magnitude corresponds to a spin Hall angle of $\approx 10^{-3}$ in the regime of small electron polarization, yet exhibits a dramatic enhancement at low temperatures and/or high biases due to the presence of polarized nuclei. This enhancement is largest for intermediate dopings, reverses sign as the samples become more metallic, and exhibits an asymmetry with respect to the absolute sign of the polarization. These features are all indicative of conduction electrons resonantly scattering from localized states in the impurity band. Further confirmation of this picture is provided by quantitative modeling of the observed magnetic field dependence at oblique angles, where the Overhauser effect partially compensates the applied field. The resulting phenomenological form demonstrates that in addition to conventional spin-orbit effects, asymmetry in the spin-flip scattering may be directly mediated by the local nuclear spin system. Supported by NSF DMR-1104951.

4:30PM C18.00011 Large magnetoresistance on spin injection in InSb/CoFe junctions , MARTIN RUDOLPH, Y.J. KIM, J.J. HEREMANS, Virginia Tech — During electrical spin injection from micron-sized ferromagnetic CoFe structures into the strongly spin-orbit coupled semiconductor InSb, we observe an unanticipated magnetoresistance at low temperatures. For temperatures below 3.5 K, the interface resistance falls abruptly, by up to 25%, at a critical magnetic field. The functional dependence on magnetic field of the magnetoresistance and the temperature and angular dependence of its amplitude and width are not consistent with previously observed magnetoresistive semiconductor/ferromagnet junction phenomena. A differential conductance map of the density of states shows a symmetric minimum at zero current bias corresponding to the magnetoresistance maximum. The experimental observations appear consistent with formation of a quasiparticle gap of width approximately 0.5 meV during a phase transition in spin polarized InSb for temperatures below 3.5 K and magnetic fields below a critical field (DOE DE-FG02-08ER46532).

4:42PM C18.00012 Carrier density dependence of the spin lifetime in the persistent photoconductor Si:$Al_{0.3}Ga_{0.7}As$[1] , JOON-IL KIM, J. MISURACA, K. KOUNTOURIOTIS, S. VON MOLNAR, P. XIONG, Florida State University, Florida, USA, K. MENG, J. LU, L. CHEN, X. YU, J. ZHAO, Institute of Semiconductors, CAS, Beijing, China — Electrical spin injection/detection experiments have been performed on Si:$Al_{0.3}Ga_{0.7}As$, a persistent photoconductor. The carrier density of this material can be tuned in situ via photo excitation across the insulator-metal transition (IMT) [1], which enables spin accumulation and transport measurements in one and the same sample over orders of magnitude variation in carrier density, thus circumventing the difficulties of making many replicas to realize different doping levels. Fe/AlGaAs heterostructures were grown by MBE, in which AlGaAs and GaAs graded Schottky junctions were tested for optimum spin injection. Spin transport devices, suitable for 3-terminal and non-local 4-terminal Hanle-type measurements and on-chip determination of the carrier density, were fabricated from the wafers. The spin lifetimes, determined from fits of the Hanle curves to a Lorentzian or the spin drift-diffusion model, range from 0.5 ns to 2.8 ns and exhibit a nonmonotonic carrier density dependence possibly peaked at the IMT.

5:06PM C18.00014 Determination of Spin Polarization of $Fe_{65}Si_5$ Using Andreev Reflection Spectroscopy

, JONATHAN MARTINEZ, CHARLES SNIDER, JESSICA GIFFORD, TINGYONG CHEN, Arizona State University — Ferromagnetic Fe_xSi_{1-x} alloys have been proposed as potential spin injectors into silicon with a substantial spin polarization. Experimentally, however, the observed spin polarization of the alloys still remains low. Ideally, spin polarization of a metal is defined as the imbalance of density of states at the Fermi level, but in amorphous alloys it is different since the Fermi level is not well defined. Recently, it has been found that the magnetic properties of the amorphous Fe_xSi_{1-x} alloys are very different from the crystalline phase. In this work, we utilize Andreev Reflection Spectroscopy (ARS) to determine the spin polarization of both amorphous and crystalline $Fe_{65}Si_{35}$ alloys. We show that the additional resistance in ARS is quite high because of large resistivity of these alloys and must be taken into account to correctly extract the spin polarization. The obtained spin polarization values are very different: the amorphous phase has a significantly higher spin polarization than that of the crystalline phase.

5:18PM C18.00015 Spin Transistor Action from Hidden Onsager Reciprocity[1]

, I. ADAGIDELI, Sabanci University, V. LUTSKER, M. SCHEID, Regensburg University, PH. JACQUOD, University of Arizona, K. RICHTER, Regensburg University — We investigate generic Hamiltonians for confined electrons with weak inhomogeneous spin-orbit coupling [1]. Using a local gauge transformation we show how the SU(2) Hamiltonian structure reduces to a U(1) × U(1) structure for spinless fermions in a fictitious orbital magnetic field, to leading order in the spin-orbit strength. Using an Onsager relation, we further show how the resulting spin conductance vanishes in a two-terminal setup, and how it is turned on by either weakly breaking time-reversal symmetry or opening additional transport terminals, thus allowing one to switch the generated spin current on or off. We numerically check our theory for mesoscopic cavities as well as Aharonov-Bohm rings.

2:30PM C19.00001 Phase transition transistors based on strongly-correlated materials[1]

, MASAKI NAKANO, RIKEN Advanced Science Institute — The field-effect transistor (FET) provides electrical switching functions through linear control of the number of charges at a channel surface by external voltage. Controlling electronic phases of condensed matters in a FET geometry has long been a central issue of physical science. In particular, FET based on a strongly correlated material, namely "Mott transistor," has attracted considerable interest, because it potentially provides gigantic and diverse electronic responses due to a strong interplay between charge, spin, orbital and lattice. We have investigated electric-field effects on such materials aiming at novel physical phenomena and electronic functions originating from strong correlation effects. Here we demonstrate electrical switching of bulk state of matter over the first-order metal-insulator transition [1]. We fabricated FETs based on VO_2 with use of a recently developed electric-double-layer transistor technique, and found that the electrostatically induced carriers at a channel surface drive all preexisting localized carriers of 10^{22} cm^{-3} even inside a bulk to motion, leading to bulk carrier delocalization beyond the electrostatic screening length. This non-local switching of bulk phases is achieved with just around 1 V, and moreover, a novel non-volatile memory like character emerges in a voltage-sweep measurement. These observations are apparently distinct from those of conventional FETs based on band insulators, capturing the essential feature of collective interactions in strongly correlated materials. This work was done in collaboration with K. Shibuya, D. Okuyama, T. Hatano, S. Ono, M. Kawasaki, Y. Iwasa, and Y. Tokura.

3:06PM C19.00002 Optical Characterization of Structural Evolution of UltrathinVO2 Films across Metal-Insulator Transition

, L. GUO, Penn State University — We use ultrafast x-ray diffraction, time resolved pulsed THz spectroscopy and infrared transient absorption techniques to study the structural and electronic evolution of photo-induced ultrathin VO_2 film epitaxied on Titanium Dioxide (TiO_2) substrate. We have demonstrated the lattice structural state of VO_2 film can be tunable by the amount of excitation fluence. The structural evolution in nanosecond scale can be understood by thermal transport model simulation done by comsol. At high excitation fluence (as high as 29mj/cm^2), a new transient state is observed based on the x-ray diffraction result. The transient structure is unambiguously identified to benon-thermally induced and decoupled from metal-insulator electronic phase transition. It recovers to the tetragonal phase within one nanosecond, and further to the monoclinic phase in tens of nanoseconds. Moreover, the lattice vary properties are highly dependent on the orientation of substrate. The lattice expands along surface normal axis in VO_2/TiO_2 (100) films while contracts in VO_2/TiO_2 (001) films when going through the phase transition region.

3:18PM C19.00003 The field-effect in vanadium dioxide and the metal-insulator transition[1]

, KOEN MARTENS, IBM Almaden / ESAT-KULeuven / imec, JAE-WOO JEONG, IBM Almaden / UC Santa Barbara, NAGAPHANI AETUKURI, IBM Almaden / Stanford University, CHARLES RETTNER, LI GAO, BRIAN HUGHES, KEVIN ROCHE, MAHESH SAMANT, S.S.P. PARKIN, IBM Almaden — VO_2 and its metal-insulator transition are currently of interest to enhance understanding of metal-insulator transitions and for investigating possible applications in nanoelectronic devices. Inducing the metal-insulator transition by means of an electric field, instead of by changing the temperature, could entail a major enhancement of present-day nano-electronics. Both the field induced metal-insulator transition and the regular semiconductor field-effect are investigated in this work using monocrystalline VO_2 field-effect structures. The field dependent VO_2 conduction characteristics across the metal-insulator transition are elucidated. The relation of these VO_2 characteristics with the VO_2-insulator interface is clarified by means of admittance analysis.

3:30PM C19.00004 Current induced Metal-Semiconductor Transition in VO2 grown on Pt

, JIWEI LU, SALINPORN KITTIWATANAKUL, STUART WOLF, University of Virginia — Vanadium dioxide (VO_2) exhibits a metal-semiconductor transition at 340K; this transition can also be triggered by an electric field or direct current injection. In this study VO_2 was grown on 100 nm thick Pt bottom electrodes. The top Pt contacts were added for the transport measurements. The transport behavior indicated a reduced transition temperature. We have shown that the switching voltage for a Pt/VO2/Pt structure was as low as 0.3 V, and at this voltage we observed two orders of magnitude change in the resistance. XPS will be used to determine the valence state.

3:42PM C19.00005 Electrical Breakdown in a V2O3 device at the Insulator to Metal Transition

, S. GUÉNON, SIMING WANG, J.G. RAMÍREZ, IVAN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California, San Diego, S. SCHARINGER, D. KOELLE, R. KLEINER, Physikalisches Institut and Center for Collective Quantum Phenomena, Universität Tübingen, Auf der Morgenstelle 14, D-72076 Tübingen, Germany — We have measured the electrical properties of a V2O3 thin film micro bridge at the insulator metal transition (IMT). Discontinuous jumps to lower voltages in the current voltage characteristic (IV) followed by an approximately constant voltage progression for high currents indicate an electrical breakdown of the device. In addition, the IV curves show hysteresis and a training effect, i.e. the subsequent IV loops are different from the first IV loop after thermal cycling. Low temperature scanning electron microscopy (LTSEM) reveals that the electrical breakdown over the whole device is caused by the formation of electro-thermal domains (ETDs), i.e. the current and temperature redistribution in the device. On the contrary, at the nanoscale, the electrical breakdown causes the IMT of individual domains. In a numerical model we considered these domains as a network of resistors and we were able to reproduce the electro-thermal breakdown as well as the hysteresis and the training effect in the IVs. This work was supported by AFOSR grant number FA9550-12-1-0381.

3:54PM C19.00006 Strain control and the triple point of the metal-insulator transition in vanadium dioxide[1]

, JAE HYUNG PARK, JIM COY, SERKAN KASIRGA, ZAIYAO FEI, CHUNMING HUANG, DAVID COBDEN, University of Washington — We have developed an apparatus for applying controlled strain to suspended nanostructures while carrying out optical and transport measurements. This platform enables us to control and study phenomena where strain plays a key role, such as the metal-insulator transition in vanadium dioxide. The relationship between the metallic (R) phase and the two insulating (M1 and M2) phases involved in this first-order solid-state transition remains intriguing. Due to the different lattice constants of the phases, controlling the length of a VO2 nanobeam allows us to study the transitions between them methodically as a function of temperature and strain. One of our findings is that the triple point temperature of these three phases is extremely close to the transition temperature at zero strain, suggesting that the balance between M1 and M2 controls the stability of the metallic phase.

[1]Supported by Department of Energy grant BES DE-SC0002197

4:06PM C19.00007 Temperature dependence of laser induced insulator-metal transition in VO_2[1]

, SIMING WANG, Center for Advanced Nanoscience, University of California San Diego, La Jolla, California, USA, SHIMSHON BAR-AD, Tel Aviv University, Tel Aviv, Israel, JUAN GABRIEL RAMIREZ, Center for Advanced Nanoscience, University of California San Diego, La Jolla, California, USA, DAN HUPPERT, Tel Aviv University, Tel Aviv, Israel, IVAN K. SCHULLER, Center for Advanced Nanoscience, University of California San Diego, La Jolla, California, USA — We performed optical pump-probe experiments on VO_2 thin films with low laser fluence at temperatures ranging across the insulator-metal transition (IMT). At room temperature, the reflectivity of VO_2 increases in the first 400-500 fs when pumped by 150 fs laser pulses. An exponential decay of the reflectivity is observed in the following 1 ps. Interestingly, as the temperature approaches the transition temperature (340 K), the reflectivity shows a second increase on an 80 ps time scale following the exponential decay, indicating an IMT. We propose that the decay of the reflectivity is due to electron-phonon thermalization, which raises the phonon temperature and causes a superheating of the lattice. This process provides the latent heat and induces the IMT on the 80 ps time scale. The coexistence of the insulating and metallic phases is observed in the reflectivity measurements for temperatures above 340 K.

4:18PM C19.00008 Conductance Modulation across the Metal-Insulator Transition in Single Nanowire Devices of doped-VO_2 Gated with Ionic Liquid

, ADAM STABILE, LUISA WHITTAKER, SARBAJIT BANERJEE, G. SAMBANDAMURTHY, University at Buffalo, State University of New York — Studies of the effects of charge modulation in VO_2 systems may provide useful insights into the microscopic mechanisms behind its metal-insulator transition (MIT). Recently, ionic liquid (IL) has become a popular material for gating nanodevices due to its superior charge accumulation capabilities. Thus, using IL to gate single nanowires of W-doped-VO_2, we systematically study the modulation of electrical transport across the temperature-driven and voltage-driven MIT as a function of gate voltage. We report the manifestation of hysteresis loops, which show an unprecedented modulation of resistance and current by as large as 20%. Moreover, we show that the largest modulation loop coincides with the largest changes in resistance across the temperature-driven MIT suggesting that the memory behavior in VO_2 and its MIT are closely linked. Similar behavior is also observed across the voltage-driven MIT. These studies lay the ground work for an alternative approach to understanding the mechanisms behind the MIT in VO_2 systems when driven by different external parameters.

4:30PM C19.00009 Decoupling of structural and electronic phase transitions in VO_2[1]

, ZHENSHENG TAO, TZONG-RU T. HAN, SUBHENDRA D. MAHANTI, PHILLIP M. DUXBURY, FEI YUAN, CHONG-YU RUAN, Physics and Astronomy Department, Michigan State University, East Lansing, Michigan 48824, USA, KEVIN WANG, JUNQIAO WU, Department of Materials Science and Engineering, University of California, Berkeley, California 94720, USA, CHONG-YU RUAN TEAM, JUNQIAO WU TEAM — Using optical, TEM and ultrafast electron diffraction experiments we find that single crystal VO_2 microbeams gently placed on insulating substrates or metal grids exhibit different behaviors, with structural and metal-insulator transitions occuring at the same temperature for insulating substrates, while for metal substrates a *new monoclinic metal phase* lies between the insulating monoclinic phase and the metallic rutile phase. The structural and electronic phase transitions in these experiments are strongly first order and we discuss their origins in the context of current understanding of multi-orbital splitting, strong correlation effects and structural distortions that act cooperatively in this system.

4:42PM C19.00010 Modulation of single-crystal vanadium dioxide film by hydrogen

, HENG JI, Department of Physics and Astronomy, Rice University, WILL HARDY, Applied Physics Graduate Program, Rice Quantum Institute, HANJONG PAIK, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — Vanadium Dioxide is a strongly correlated material with a bulk metal-to-insulator transition at 340 K. This transition temperature can be affected by strain, and previous experiments in single-crystal nanowires (J. Wei et al., Nature Nano. 7, 357-362 (2012)) have shown that catalytic doping with atomic hydrogen can stabilize the high temperature metallic state. In this experiment, we examine the effects of hydrogen on a 10 nm thick VO_2 film grown on TiO_2 (001) substrate by MBE with a transition temperature at 280K. We found the transport properties of this film can be dramatically modulated by doping and releasing hydrogen in and out of VO2 film even at room temperature. The resulting changes in the conductivity are even more dramatic than those seen in nanowires. The enhanced rate of response at room temperature is likely aided by the crystallographic orientation of the film, which has a growth direction along which hydrogen is known to diffuse rapidly in rutile TiO_2, which is isostructural to the metallic VO_2 high temperature phase.

4:54PM C19.00011 Bi-chromatic probing of the metal-insulator transition in VO2 thin film , LEI WANG, IRINA NOVIKOVA, The College of William and Mary, Physics Department, MICHAEL KLOPF, FEL-T. Jefferson National Accelerator Facility, ERIC MADARAS, NASA Langley Research Center, SCOTT MADARAS, GWYN WILLIAMS, FEL-T. Jefferson National Accelerator Facility, ROSA LUKASZEW, The College of William and Mary, Physics Department — VO2 is a correlated electron material that exhibits a metal-insulator (MIT) phase transition that can be thermally, electrically, or optically controlled. For the thermally-induced case the material undergoes a structural transition from a monoclinic insulating state to rutile metal at around 340K. The salient features of this first order phase transition are that upon the transition the material exhibits up to five orders-of-magnitude increase in conductivity and consequently also significant changes in the optical properties. Typically in these oxides, competing states can often coexist and form nano- or microscale domains of different phases while transitioning. Here we show that upon thermally inducing the MIT on epitaxial VO2 films when simultaneously probed by two very different frequencies- namely IR and THz- the onset of the MIT appears at somewhat different temperature depending on the light used to probe it, thus confirming the coexistence of nano-scale domains of different phases. We will show our correlated far field optical and transport studies on these films to investigate the percolative nature of the transition and applied mean field approximations to model the observed response.

5:06PM C19.00012 Role of joule heating in electrically-driven metal insulator transition in vanadium oxide nanowires , SUJAY SINGH, ZHENZHONG SHI, CHUN PUI KWAN, Department of Physics, PETER MARLEY, SARBAJIT BANERJEE, Department of Chemistry, GANAPATHY SAMBANDAMURTHY, Department of Physics, University at Buffalo, Buffalo, NY 14260 — Metal to insulator transition (MIT) in vanadium oxide system can be triggered by several external stimuli such as temperature, electric field, strain and light. Electrically driven MIT in single nanowire devices of crystalline vanadium oxide (W- doped VO_2, Ag-doped V_2O_5) is the topic of current study. Recent works on realizing switching devices using these materials have discussed the importance of Joule heating near the transition as supposed to a purely electric field induced effect. We propose a novel method for identifying the individual roles of Joule heating and/or electric field by analyzing the frequency response of the AC electric signal near the MIT in these devices. The method may also be used in other strongly correlated electron system to delineate the roles of individual microscopic conduction mechanisms near MIT.

5:18PM C19.00013 Switchable vanadium dioxide (VO2) metamaterials fabricated from tungsten doped vanadia-based colloidal nanocrystals[1] , TAEJONG PAIK, SUNG-HOON HONG, THOMAS GORDON, ASHLEY GAULDING, CHERIE KAGAN, CHRISTOPHER MURRAY, University of Pennsylvania — We report the fabrication of thermochromic VO2-based metamaterials using solution-processable colloidal nanocrystals. Vanadium-based nanoparticles are prepared through a non-hydrolytic reaction, resulting in stable colloidal dispersions in solution. Thermochromic nanocrystalline VO2 thin-films are prepared via rapid thermal annealing of colloidal nanoparticles coated on a variety of substrates. Nanostructured VO2 can be patterned over large areas by nanoimprint lithography. Precise control of tungsten (W) doping concentration in colloidal nanoparticles enables tuning of the phase transition temperature of the nanocrystalline VO2 thin-films. W-doped VO2 films display a sharp temperature dependent phase transition, similar to the undoped VO2 film, but at lower temperatures tunable with the doping level. By sequential coating of doped VO2 with different doping concentrations, we fabricate ?smart? multi-layered VO2 films displaying multiple phase transition temperatures within a single structure, allowing for dynamic modulation of the metal-dielectric layered structure. The optical properties programmed into the layered structure are switchable with temperature, which provides additional degrees of freedom to design tunable optical metamaterials.

Session C20 DMP: Focus Session: Metamaterials - Quantum Dots 322 - Yanwen Wu, University of Texas at Austin

2:30PM C20.00001 Phonon-induced Transparency in Quantum Dot Molecules , M. KERFOOT, University of California, Merced, A. GOVOROV, Ohio University, D. LU, R. BABAOYE, University of California, Merced, A. BRACKER, D. GAMMON, Naval Research Laboratory, M. SCHEIBNER, University of California, Merced — Quantum dot molecules (QDMs) formed by vertically stacked quantum dots provide a rich test ground for the investigation of elementary semiconductor excitations in a zero dimensional system. A high level of control over the mutual interactions between charges, spins and photons has been achieved with the enormous tunability of electronic states in QDMs [1]. In this work, we investigate the interaction of phonons with the QDM electronic states and demonstrate that, contrary to their usual dephasing role, phonons can actually increase control over a quantum system. This novel employment of phonons arises from the formation of a resonance-enhanced polaron. It is revealed via a Fano effect that arises from the interference of two competing optical absorption pathways, which results in a transparency of the system. One pathway involves a discrete electronic excitation with charges localized in separate quantum dots. The other pathway is for a polaron state, a hybrid of an electronic excitation with an optical phonon that results in a continuum of energy states. The pathways are coupled by the tunneling of a single hole, resulting in a Fano interference in the absorption lineshape characterized by stark dips (transparency) and peaks in the absorption. We show that the phonon-induced transparency is highly controllable by electric field, excitation energy and power.

2:42PM C20.00002 Structural characterization and magnetotransport in Ge/Si quantum dots[1] , DONGYUE YANG, Department of Physics and Astronomy, University of Pittsburgh, CHRIS PETZ, JERROLD FLORO, Department of Materials Science and Engineering, University of Virginia, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Artificially ordered quantum dot (QD) arrays may create unique functionalities such as cluster qubits and spintronic bandgap systems.[2] We fabricate directed self-assembled Ge/SiC/Si arrays with fine control over QD size and spatial arrangement on the sub-35 nm length scale for this purpose. The formation, thermal stability, and structure of the QDs are studied extensively with transmission electron microscopy (TEM) and atomic force microscopy (AFM).[3] Magnetotransport measurements through the QD arrays shows a diamagnetic shift that depends on the dots' spatial configuration. We attribute this configuration dependence to the interaction of the electrons between different QDs.

2:54PM C20.00003 Tuning between Quantum-Dot and Quantum-Well-Like Behaviors in Type-II Zn-Se-Te Multilayers by Controlling Tellurium Flux during MBE Growth[1] , HAOJIE JI, Queens College of CUNY; Graduate Center of CUNY, BIDISHA ROY, SIDDHARTH DHOMKAR, Queens College of CUNY, RICHARD MOUG, MARIA TAMARGO, City College of CUNY, ALICE WANG, Evans Analytical Group, IGOR KUSKOVSKY, Queens College of CUNY — Type-II semiconductor quantum dots (QDs) characterized by spatial separation of charge carriers are good candidates for such applications as intermediate-band solar cells and IR photodetectors. Type-II QDs differ from type-I counterparts because one type of the carriers locates within the barrier material, so that their wavefunctions become to overlap early with increasing QD density. Thus, it is expected that type-II QDs coalescence into a - quantum well (QW) - like layer at much lower densities than similar type-I QDs with obvious consequences for device performance. We report here tuning between QD- and QW-like behaviors in the Zn-Se-Te multilayers with ZnTe sub-monolayer QDs. A set of samples, grown with increasing Tellurium flux, have been investigated. The critical density of QDs and the overlap of electron wavefunctions are estimated from secondary ion mass spectrometry, temperature dependent photoluminescence (PL), and magneto-PL measurements.

3:06PM C20.00004 Effect of built-in electric field in stacked type-II ZnTe/ZnSe submonolayer quantum dots: enhancement and narrowing of Aharonov-Bohm oscillations[1] , BIDISHA ROY, SIDDHARTH DHOMKAR, HAOJIE JI, Queens College of CUNY, MARIA TAMARGO, The City College of New York of CUNY, IGOR KUSKOVSKY, Queens College of CUNY — Robust and narrow Aharonov-Bohm (AB) oscillations were observed in both intensity and energy of the mangeto-photoluminescence (PL) from stacked type-II ZnTe/ZnSe submonolayer quantum dots (QDs) grown via migration enhanced epitaxy. The narrowness and enhancement in the AB oscillations is a consequence of the built-in electric field in the system. Spectral analysis of cw magneto-PL and time-resolved PL suggest that the QD stacks size distribution is not large and thus broadening of the PL is possibly due to strong electron-phonon interaction as generally seen in bulk Zn-Se-Te systems.

3:18PM C20.00005 Characterizing epitaxially-grown InGaAs quantum dot chains using transmission electron microscopy , TYLER PARK, JOHN COLTON, Brigham Young University, HAEYEON YANG, South Dakota School of Mines and Technology, JEFF FARRER, Brigham Young University — Quantum dot chains grown by a modified Stranski-Krastanov method have been studied. The new growth technique seeks to reduce indium segregation and intermixing, compared to the conventional method, for higher quality dots. These quantum dot chains may have potential application in optoelectronics, detectors, lasers, and quantum computing. Our recent efforts have been to characterize the quantum dot chains by using transmission electron microscopy to answer morphological questions that photoluminescence spectroscopy could not. Using this method, we've been able to observe a dependence of dot flattening on temperature, a reduction in segregation and intermixing, and little influence of a capping layer on the structure of the dot-chains.

3:30PM C20.00006 Electric-field control of exciton fine structure: atomic scale manipulation of exchange , GARNETT BRYANT, NATALIA MALKOVA, JAMES SIMS, National Institute of Standards and Technology — Tremendous effort has been made recently to control excitons in semiconductor quantum dots using vertical and in-plane electric fields, magnetic fields, optical fields, strain fields, annealing and crystal symmetry to manipulate exciton phase, fine structure splitting and polarization. Such control enables entangled photon generation from biexciton cascade, coherent state manipulation, and transfer between flying photonic qubits and stationary solid-state qubits needed for quantum information processing. We use atomistic tight-binding theory with a configuration interaction description of Coulomb and exchange effects to describe excitons in quantum dots in a vertical electric field. We show that field-induced manipulation of exciton orientation and phase produces a drastic reduction of fine structure splitting, an anticrossing, and a 90 degree rotation of polarization, similar to the observed anticrossing. An *atomistic* analysis is needed to explain how exciton reorientation by the applied field modifies anisotropic exchance and fine structure splitting without significantly altering other splittings.

3:42PM C20.00007 Enhanced Luminescence in Tb/Ce co-doped Zinc- and Tin-Oxide quantum dots , CHRISTIE LAROCHELLE, JINGJING XU, Franklin & Marshall College, KELLY MCCUTCHEON, Virginia Tech — SnO_2 and ZnO quantum dots doped with Tb^{3+} exhibit strong luminescence from the Tb^{3+} dopants due to efficient energy transfer from the semiconductor donors to the Tb^{3+} acceptor ions. We report results from a study of the effect of co-doping the SnO_2 and ZnO dots with both Tb^{3+} and Ce^{3+} on the photoluminescence properties of the samples. The dots were synthesized using a sol-gel technique and the Ce^{3+}/Tb^{3+} ratio was varied while keeping the total doping level at 1wt%. X-ray diffraction and TEM results confirm the presence of nanocrystals of less than 10 nm in diameter. Photoluminescence results indicate that the Tb^{3+} ions are incorporated in a crystalline environment and that co-doping with Ce^{3+} enhances the energy transfer efficiency and therefore the intensity of the Tb^{3+} luminescence. The effect of heat treatment on the size of the dots and the impact of size on luminescence properties was also investigated.

3:54PM C20.00008 Emission in Mn-Doped Quantum Dot , QUE HUONG NGUYEN, Marshall University, JOSEPH L. BIRMAN, City College, CUNY — We theoretically investigate the magneto-PL of Mn2+doped semiconductor core-shell colloidal quantum dot to explain the experiment result from a recent magnetophotoluminescence study of strongly confined diluted magnetic semiconductor (DMS) in Mn2+-doped ZnSe/CdSe core-shell colloidal nanocrystals. The yellow emission characterized for in Mn2+-which is associated with the d-d internal transition 4T1-6A1, was reported not suppressed in an applied B //z magnetic field and unpolarized as usual and instead, a Mn PL circular polarization has been observed. The in Mn2+-photoluminescence has been found to have a large splitting between σ^+ and σ^- components which depends on the applied field. We show that this behavior, which has not been found in characteristics of the Mn2+ PL in bulks and other conventional DMS materials, is the result of the strong confinement of the nanocrystal and its properties. Our theory and calculation show that the reasons the yellow Mn2+ PL band in quantum dots is not suppressed under applied magnetic field originate due to the existence of the internal piezoelectric dipole moment and the Coulomb exchange interaction of the impurity ions with the confined electrons inside the dot.

4:06PM C20.00009 Modification of the conduction band edge energy via hybridization in quantum dots , ROBERT MEULENBERG, JOSHUA WRIGHT, University of Maine — X-ray absorption near edge structure spectroscopy (XANES) and theoretical modeling are used to examine effects of hybridization on the conduction band edge in doped CdSe quantum dots (QDs). Experimentally, Cd M_3-edge XANES provides evidence for a lowering of the CB minimum for Cu doped CdSe QDs that is dependent on Cu concentration. Theoretical modeling suggests the effects of hybridization between Cu and Cd atoms in the QD can explain our experimental results. The model can be extended for other dopant systems and provide a simple, yet effective, method to predict the effects of hybridization on the CB levels in QDs.

4:18PM C20.00010 An evaluation of optical properties of solution processed colloidal chalcogenide type nanocrystals , PRASHANT SARSWAT, MICHAEL FREE, University of Utah — Solution cast cadmium free chalcogenide type quantum dots were synthesized using environmentally friendly constituent elements. Some of the advantages of solution cast nanocrystals are easy integration with desired substrate, good control over size and shape, and their rapid processing. A range of liquid with different color luminescence was produced by changing the solvent and synthesis conditions. A green color luminescence was produced when oleylamine is used as a solvent and inert condition is maintained, whereas yellow luminescence was observed when syntheses of crystals were carried out in presence of oxygen. Detailed characterization and investigation was conducted using transmission electron microscopy, X-ray photoelectron spectroscopy, Raman spectroscopy, and photoluminescence study.

4:30PM C20.00011 Ensemble brightening in size purified silicon nanocrystals , JOSEPH B. MILLER, AUSTIN R. VANSICKLE, NDSU, REBECCA J. ANTHONY, University of Minnesota, DANIEL M. KROLL, NDSU, UWE R. KORTSHAGEN, University of Minnesota, ERIK K. HOBBIE, NDSU — We report on the quantum yield, photoluminescence (PL) lifetime and ensemble photoluminescent stability of monodisperse plasma-synthesized silicon nanocrystals (SiNCs) prepared though density-gradient ultracentrifugation in mixed organic solvents. Improved size uniformity leads to a reduction in PL linewidth, band alignment, and the emergence of entropic order in dry nanocrystal films. We find a significant PL enhancement in thin solid films assembled from the fractions, and we use a combination of measurement, simulation and modeling to link this brightening to a temporally enhanced quantum yield arising from SiNC interactions in ordered ensembles of monodisperse nanocrystals. Using an appropriate excitation scheme, we exploit this enhancement to achieve photostable emission.

4:42PM C20.00012 Ligand Interface Chemistry of Lead Chalcogenide Nanocrystals[1] , KUN LIU, Cornell, CLIVE BEALING[2], University of Connecticut, RICHARD HENNIG, Cornell, HENNIG GROUP TEAM — Lead chalcogenides nanocrystals (NCs) have shown promise in photovoltaic applications. Surface chemistry is one of the most important, yet least understood aspects of NC synthesis and functionalization controlling their properties. For example, an incomplete surface passivation could create trap states that enhance undesired exciton recombination. Clever choices of ligands ensure that neighboring NCs are electronically coupled while maintaining their quantum size effects. These two barriers limiting performance of NC solar cells illustrate the importance of fundamental studies for the interaction between ligands and NC surfaces. We use density functional theory to determine the binding sites and energies of ligands commonly used in NC synthesis and functionalization. Specifically we study amine-, carboxyl-, and thiol-ligands on different PbSe and PbS surfaces. For methylamine ligands we find a similar binding energy on the (100) and (111) facet while carboxylic acid ligands strongly prefer the (111) facet leading to different effective NC shapes.

4:54PM C20.00013 Surfaces of nanomaterials for sustainable energy applications: thin-film 2D-ACAR and PALS studies[1] , B. BARBIELLINI, Northeastern University, L. CHAI, Delft U. Tech., W. AL-SAWAI, Northeastern U., S.W.H. EIJT, P.E. MIJNARENDS, H. SCHUT, Y. GAO, A.J. HOUTEPEN, Delft U. Tech., L. RAVELLI, W. EGGER, U. der Bundeswehr Muenchen, M.A. VAN HUIS, Utrecht U., A. BANSIL, Northeastern U. — Positron (e^+) annihilation spectroscopy is one of only a few techniques to probe the surfaces of nanoparticles. We investigated thin films of PbSe colloidal semiconductor nanocrystals (NCs) in the range 2-10 nm as prospective highly efficient absorbers for solar cells. We compare and contrast our findings with previous studies on CdSe NCs. Evidence obtained from our e^+ lifetime spectroscopy study using the PLEPS spectrometer shows that 90-95% of the implanted positrons are effectively trapped and confined at the surfaces of these NCs. The remaining 5-10% of the e^+ annihilate in the relatively large oleic acid ligands, in fair agreement with the estimated positron stopping power of the PbSe nanoparticle "core" relative to the ligand "shell." 2D-ACAR measurements on the same set of films using the low-energy e^+ beam POSH showed that the e^+ wavefunction at the surfaces of the PbSe NCs is more localized than for the case of CdSe NCs. Comparison with calculated e^+ - e^- momentum densities indicates a Pb deficiency at the surfaces of the PbSe NCs, which correlates with e^+ lifetime and the NCs morphology.

5:06PM C20.00014 Polymer Matrix Role in Light Absorption and Emission by Nano-CdS/PVA Composite[1] , ANDRII KOVALCHUK, GALYNA RUDKO, V. Lashkaryov Institute of Semiconductor Physics of National Academy of Sciences of Ukraine, VOLODYMYR FEDIV, Department of Biophysics and Medical Informatics, Bukovinian State Medical University, QIJUN REN, IRINA BUYANOVA, WEIMIN CHEN, Department of Physics, Chemistry and Biology, Linköping University, DEPARTMENT OF OPTICS TEAM, DEPARTMENT OF BIOPHYSICS AND MEDICAL INFORMATICS TEAM, DEPARTMENT OF PHYSICS, CHEMISTRY AND BIOLOGY TEAM — Influence of a polymeric medium on the light absorption and emission processes of composite nano-CdS/polyvinyl alcohol is studied by activating different absorption-emission routes via changing of excitation wavelengths. The mechanisms are analyzed by employing the time-resolved photoluminescence spectroscopy. It is shown that the polymeric component of the composite contributes mainly to the excitation processes of photoluminescence via absorption of external laser excitation and its following transfer to the CdS nanoparticles that are incorporated into polymer matrix. The composite emission occurs mostly within the nanoparticles. It is also shown that time-decays of the photoluminescence emission from the CdS nanoparticles embedded in the composite depend on the excitation wavelength. Such behavior is ascribed to the interplay between the intrinsic nanoparticles excitation and extrinsic feeding of the nanoparticles via energy transfer from the excited polymer matrix. Possible mechanisms of the observed energy transfer are also discussed.

5:18PM C20.00015 Water-soluble metallic cluster characterization via nanopore detection , CHRISOPHER E. ANGEVINE, JOSEPH E. REINER, Physics Department, Virginia Commonwealth University, Richmond, VA 23284 — Metallic quantum clusters can be ligand stabilized for aqueous environments to expand their potential as biosensors. Characterizing these clusters, while they are in solution, is an important problem because it will aid in optimizing cluster design. Nanopore-based resistive pulse sensing could be a valuable technique with which to characterize these structures because the pore is commensurate with the size of many of the clusters in use. Briefly, a single cluster enters the nanopore and creates a measurable decrease in the ionic current through the pore. These current blockades can be analyzed to deduce properties of the clusters such as size and charge. We have demonstrated this capability with a monodisperse mixture of $Au_{25}(SG)_{18}$. These clusters give rise to blockades with various mean residence times and blockade depths. We will present preliminary results and our analysis of these blockades and discuss future directions for nanopore-based cluster characterization.

Session C21 DMP: Focus Session: Domains, Switching, and Memristors 323 - James Scott, University of Cambridge

2:30PM C21.00001 Phenomenological study of switching in strongly coupled multiferroics , KUNTAL ROY, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853 — An ongoing challenge in the field of multiferroics is to understand new mechanisms and to realize new materials in which an electric field can deterministically switch the magnetization by 180° at room temperature. One mechanism that has recently become of renewed interests is that of ferroelectric-induced weak ferromagnetism, for which several new classes of materials have been proposed and found to be realizations of from first principles. An open and challenging question concerning these systems is that of polarization-magnetization dynamics such as switching. In this talk we will discuss our initial work addressing this question. We apply a phenomenological approach, e.g., the Landau-Lifshitz-Gilbert equation for magnetization dynamics and dynamical systems equations for polarization to study the switching dynamics in single-phase multiferroic materials with strongly coupled polarization and magnetization.

2:42PM C21.00002 Polarization switching dynamics in thin-film $BaTiO_3/PbZr_{0.2}Ti_{0.8}O_3$ bilayer capacitors , PAVEL SALEV, ALEXEI GRIGORIEV, The University of Tulsa — In this work, we compare polarization switching and dielectric properties of single- ($PbZr_{0.2}Ti_{0.8}O_3$ (PZT)) and bi-layer ($BaTiO_3/PbZr_{0.2}Ti_{0.8}O_3$ (BTO/PZT)) ferroelectric thin-film materials. The ferroelectric films were grown by radio-frequency magnetron sputtering on $SrRuO_3/SrTiO_3$ (001) substrates. Pt top electrodes ranging in diameter from 50 um to 200 um were fabricated on top of ferroelectric films. Electrical measurements of switching dynamics and dielectric response revealed a significant difference in polarization switching between single- and bi-layer capacitors. Average remnant polarization in the bilayer was reduced to 60 uC/cm^2 from 90 uC/cm^2 polarization in a single layer capacitor, and the switching speed was reduced significantly. In this presentation, we will discuss effects of interfaces and polarization coupling on polarization dynamics and on the dielectric response in ferroelectric multilayers.

2:54PM C21.00003 Domain Switching and Interaction with Misfit Dislocation in Bismuth Ferrite thin films: Phase-Field Simulation , KHALID ASHRAF, SAYEEF SALAHUDDIN, EECS Dept, UC Berkeley, EECS DEPT BERKELEY TEAM — Previously, we reported a massively parallel 3D phase-field model that can simulate micron scale ferroelectric thin films with arbitrary electrical and mechanical boundary conditions [1,2]. Using this model, we explained a number of recent experimental results of domain switching on various surfaces of BiFeO3 [1,2]. Here, we study the inhomogeneous strain distribution and its impact on domain nucleation and switching in the multi-ferroic material BiFeO3. We calculate the inhomogeneous strain induced in a thin film BiFeO3 due to misfit dislocations. We simulate the domain growth mechanism in films with and without misfit dislocation. We find that a compressively strained region in the film due to dislocation act as nucleation center whereas a tensile strained region act as pinning centers for lateral electric fields on the (001) surface of BFO. Both domain growth and relaxation speed are considerably higher close to a compressively strained region when the domain propagates perpendicular to the dislocation. An opposite trend is observed for domains relaxing along the dislocation. Our calculated domain propagation velocities are in excellent agreement with recently reported experiments.

3:06PM C21.00004 Ferroelectric and multiferroic domain imaging by Laser-induced photoemission microscopy , ANKE HOEFER, Institute of Physics, Martin Luther University Halle-Wittenberg, MICHAEL FECHNER, Max Planck Institute of Microstructure Physics Halle, KLAUS DUNCKER, INGRID MERTIG, WOLF WIDDRA, Institute of Physics, Martin Luther University Halle-Wittenberg — The ferroelectric as well as multiferroic surface domain structures of BaTiO3(001) and BiFeO3(001) are imaged based on photoemission electron microscopy (PEEM) by femtosecond laser threshold excitation under UHV conditions [1]. For well-prepared BaTiO3(001), three ferroelectric domain types are clearly discriminable due to work function differences. At room temperature, the surface domains resemble the known ferroelectric domain structure of the bulk. Upon heating above the Curie point of 400 K, the specific surface domain pattern remains up to 500 K [2]. Ab-initio calculations explain this observation by a remaining tetragonal distortion of the topmost unit cells stabilized by a surface relaxation. The (001) surface of the single-phase multiferroic BiFeO3 which is ferroelectric and antiferromagnetic, shows clear ferroelectric work function contrast in PEEM. Additionally, the multiferroic domains show significant linear dichroism. The observation of a varying dichroism for different ferroelectric domains can be explained based on the coupled ferroelectric-antiferromagnetic order in BiFeO3. It demonstrates multiferroic imaging of different domain types within a single, lab-based experiment. [1]Hoefer et al., IBM J. Res. Dev. 55, 4:1 (2011) [2]Hoefer et al., PRL 108, 087602 (2012)

3:18PM C21.00005 Bloch-type domain walls in rhombohedral $BaTiO_3$, MARYAM TAHERINEJAD, DAVID VANDERBILT, Rutgers University, PAVEL MARTON, VILGELMINA STEPKOVA, JIRI HLINKA, Academy of Sciences of the Czech Republic — Ferroelectric domain walls (FDWs) are usually considered to be of Ising type, but there have been suggestions in recent years that Bloch-type FDWs, in which the polarization rotates in the plane of the FDW, are also possible. The mechanically compatible and electrically neutral FDWs in rhombohedral $BaTiO_3$ are of 71°, 109°, and 180° type. We have investigated these FDWs based both on first-principles calculations and on a Ginzburg-Landau-Devonshire (GLD) model.[1] The results from both approaches confirm the Ising nature of the 71° FDW and the Bloch nature of the 180° FDW, and predict both Ising-type and Bloch-type FDWs are possible for the 109° case. Considering the relatively small rhombohedral strain in $BaTiO_3$, the competition between the energies of Bloch and Ising FDWs can be discussed in terms of a picture in which a Bloch wall is regarded as being composed of a pair of smaller-angle Ising ones. A reduction by 40% in the parameters describing the gradient term in the GLD model brings it into better agreement with the first-principles results for detailed properties such as the energies and widths of the FDWs.

3:30PM C21.00006 Domain wall roughness and creep behavior in nanoscale crystalline ferroelectric oxide and polymer films , ZHIYONG XIAO, SHASHI PODDAR, STEPHEN DUCHARME, XIA HONG, Department of Physics and Astronomy, University of Nebraska-Lincoln — We have studied the static and dynamic properties of domain wall (DW) in nanoscale crystalline ferroelectric oxide $Pb(Zr,Ti)O_3$ (PZT) and poly(vinylidene-fluoride-trifluorethylene) (PVDF-TrFE) films of 20 to 40 nm thick using piezo-response force microscopy. DW roughness exponent ζ is extracted from the correlation function of DW displacement. At room temperature, ζ of PVDF-TrFE is 0.4 to 0.48, much higher than those obtained on the PZT films (0.2-0.3). Combined with the dynamic studies of the DW creep behavior, this yields an effective dimensionality of 1.5 for PVDF-TrFE films, in sharp contrast to $d_{eff} \sim 2.5$ observed in PZT films. We have also thermally quenched the DWs after heating them at high temperatures. Thermal quench causes significant change in the DW configuration in PZT films with ζ increasing to ~ 0.5 after the films are heated close to the Curie temperature T_C. On the other hand, the DWs in PVDF-TrFE films exhibit very weak temperature dependence. We attribute this distinctly different behavior to the strong anisotropy between in-plane and out-of-plane interaction in PVDF-TrFE, which is absent in PZT.

3:42PM C21.00007 Equilateral triangular ferroelectric closure domains in (111)-oriented epitaxial $Pb(Zr,Ti)O_3$ thin films , SANG MO YANG, Y.J. SHIN, T.W. NOH, CFI-CES, Institute for Basic Science, and Dept. of Physics & Astronomy, Seoul Nat'l Univ., Seoul, Korea, Y. EHARA, H. FUNAKUBO, Dept. of Innovative and Engineered Material, Tokyo Institute of Technology, Yokohama, Japan, J.-G. YOON, Dept. of Physics, Univ. of Suwon, Hwaseong, Gyunggi-do, Korea, J.F. SCOTT, Dept. of Physics, Cavendish Laboratory, Univ. of Cambridge, Cambridge, UK — Over 60 years ago, Charles Kittel predicted that intriguing quadrant flux-closure domains could spontaneously form in small ferromagnetic platelets [1]. Such quadrant flux-closure domains are considered as a precursor for the true vortex states, having attracted particular interest for storing memory devices. Although the vortex states are now ubiquitous and rather well understood in ferromagnets, even the flux-closure domains as their precursors are much less established in ferroelectrics (FEs) [2]. Here we report the generation of novel equilateral triangular FE closure domains. We generated such intriguing states by using the high crystalline anisotropy energy of a (111)-oriented epitaxial $PbZr_{0.35}Ti_{0.65}O_3$ thin film. Vector piezoresponse force microscopy analysis showed clearly the equilateral triangular closure states, consisting of three stripe domain bundles with three 120 degree orientation differences. Interestingly, the observed two closure states had the different rotation direction around the core, i.e., clockwise and anti-clockwise.

3:54PM C21.00008 Probing the Atomic Structure and Dynamics of Ferroelectric Domain Walls during Electrical Switching in Real Time[1] , XIAOQING PAN, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, Michigan 48109, USA — The ferroelectric switching occurs through the nucleation and growth of favorably oriented domains and is mediated by defects and interfaces. Dislocations, for example, are known to destroy ferroelectric order; neighboring grains and interfaces subject the ferroelectric to localized strain, electric fields, or the screening of electric fields. Thus, it is critical to understand how the ferroelectric domain forms, grows, and interacts with structural defects. This talk presents the nanoscale ferroelectric switching of $BiFeO_3$ and $PbZr_{0.2}Ti_{0.8}O_3$ thin films under an applied electric field using in situ transmission electron microscopy (TEM). We follow the kinetics and dynamics of ferroelectric switching in real time and at sub-angstrom spatial resolution. We observed localized nucleation events at the electrode interface, domain wall pinning on point defects, the formation of ferroelectric domains localized to the ferroelectric/electrode interface, and domain wall pinning by dislocations. Through a quantitative analysis of aberration-corrected TEM images we found that there is a strong structural coupling between ferroelectric film and substrate, resulting a polarization reduction in the ferroelectric layer and inducing a polar displacement in substrate.

4:30PM C21.00009 Two mechanisms of resistive memories in complex oxide thin films , KUI-JUAN JIN, CAN WANG, ZHONGTANG XU, Institute of Physics, CAS — Current-voltage hysteresis and switchable rectifying characteristics have been observed in epitaxial multiferroic $BiFeO_3$ thin films. [1, 2] It has been clearly demonstrated that ferroelectricity and conductivity coexist in a single phase. The forward direction of the rectifying current can be reversed repeatedly with polarization switching, indicating a switchable diode effect and large ferroelectric resistive switching phenomenon. $LaMnO_3$ (LMO) films are deposited on $SrTiO_3$:Nb (0.8 wt%) substrates under various oxygen pressures for obtaining various concentrations of oxygen vacancies in the LMO films. An aberration-corrected annular-bright-field scanning transmission electron microscopy with atomic resolution and sensitivity for light elements is used, which clearly shows that the number of oxygen vacancies increases with the decrease of oxygen pressures during fabrication. Correspondingly, the resistive switching property becomes more pronounced with more oxygen vacancies contained in LMO films. *E-mail: kjjin@iphy.ac.cn

4:42PM C21.00010 Shock wave mechanism for bipolar resistive switching , S. TANG, V. DOBROSAVLJEVIĆ, Florida State University, M. ROZENBERG, Univ. de Paris, Orsay — Many recently discovered systems displaying resistive switching phenomena have been widely studied as potential basis of future electronic memory devices. The hysteresis cycles observed in several such transition-metal oxide devices show a universal feature related to an abrupt onset of resistance switching. Here, we present an analytic analysis of a recently proposed phenomenological model[1], via first principle derivation of an appropriate non-linear diffusion equation describing the rapid oxygen vacancy migration under strong time-dependent external electric fields. The non-linearity effect, which reflects the vacancy concentration dependence of the local resistivity, can be related to the modified Burger's equation describing shock waves. We show that the sudden resistance drop observed in the numerical solution of the model occurs exactly when the vacancy shock wave front reaches the interface between the highly resistive Schottky barrier and the bulk. We argue that the magnitude of the relevant nonlinear term is maximal for materials in the close-vicinity of the metal-insulator transition; this insight may facilitate the the optimization of device performance.

[1]M. J. Rozenberg *et al.*, Phys. Rev. B **81**, 115101 (2010).

4:54PM C21.00011 Using Noise to Study Switching Dynamics of Oxide Memristors , A.M. BRATKOVSKY, WEI YI, G. MEDEIROS-RIBEIRO, R.S. WILLIAMS, Hewlett-Packard Laboratories, Palo Alto, CA 94304, S. SAVEL'EV, Loughborough U, United Kingdom — Oxide memristors present attractive opportunities in the areas of nonvolatile memory, random access storage, novel electronic circuits, and new cognitive computing paradigms. The progress in those areas requires detailed understanding of the origin of memristive (resistance switching) behavior, state evolution, and noise. We have found that in TaOx memristors, there is a boundary between semiconducting and metallic conductivity that is characterized by quantized conductance states, demonstrating the formation of an atomic-scale point contact within the oxide. We have measured the noise spectra of a wide range of conductance states, and observed a variety of conductance-dependent behaviors including a transition from $1/f^2$ (semiconducting regime) to $1/f$ (flicker noise in the "metallic" regime) frequency (f) dependence and a peak in the noise amplitude at the conductance quantum $G_Q = 2e^2/h$. We have modeled the point contact using stochastic molecular dynamics and can understand the observed behavior in terms of thermally-activated atomic-scale fluctuations that make and break the contact in the non-conducting matrix. The data provides important input for circuit designs and other applications of memristors.

5:06PM C21.00012 The rules of the resistive switching operation parameters based on Ta/Ta_2O_5 RRAM device[1] , HAITAO LI, GMU & NIST, CURT RICHTER, OLEG KIRILLOV, NIST, HUI YUAN, HAO ZHU, DIMITRIS IOANNOU, QILIANG LI, GMU, DEPT. ECE, GEORGE MASON UNIVERSITY TEAM, SEMICONDUCTOR AND DIMENSIONAL METROLOGY DIVISION, NIST TEAM — The resistive switching (RS) of the TaO_x based RRAM has been widely studied due to its excellent endurance and thermal stability. The RS mechanism is generally understood as the formation and dissolution of nanometer-size conductive filament (CF) formed in set and reset process, respectively. However the exact process of dielectric break down remains unknown. In this work we studied the RS of the Ta/Ta_2O_5 based RRAM devices from the dependences of operation parameters V_{set}, I_{CC}, V_{reset}, and I_{reset} on device resistance. From statistical analysis of variation in the threshold parameters, we found that the set process is mainly determined by the voltage stress on the device, instead of current. The first forming process is different from the following set process. The forming voltage exponentially depends on the pristine resistance. The forming process gives a smallest low resistance (R_{LRS}) for each device. As a result change in compliance current (I_{CC}) has no obvious effects on this low resistance state.

5:18PM C21.00013 Thermophoresis (Soret Effect) in Memristor Calculations , HAROLD HJALMARSON, PATRICK MICKEL, GAD HAASE, ANDREW LOHN, MATTHEW MARINELLA, MICHAEL MCLAIN, Sandia National Laboratory, ANDREW PINEDA, Air Force Research Laboratory — Switching in memristive devices involves the formation of conductive filaments following the application of a voltage pulse that causes heating. The temperature gradient may cause migration of atoms and vacancies through thermophoresis, also called the Soret effect or thermal diffusion. Thus thermophoresis may contribute to the switching mechanism. In this talk, the inclusion of thermophoresis in continuum calculations of electrical transport will be discussed in terms of nonequilibrium thermodynamics. These calculations include the effects of Joule heating, chemical species migration, ionizing radiation and chemical reactions. The merits of various ways to include thermophoresis will be discussed. Some illustrative results will also be discussed. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Session C22 DCMP: Metamaterials and THz Spectroscopy 324 - Matt Doty, University of Delaware

2:30PM C22.00001 Hyperbolic dispersion of graded anisotropic metamaterial with optical Kerr effect , KA SHING HUI, HON PING LEE, KIN WAH YU, The Chinese University of Hong Kong — We have investigated the tunable optical dispersion relation from an anisotropic graded material with optical Kerr effect under the influence of external electric field. The permittivity of the material depends on incident electric field $\tilde{\epsilon} = \epsilon + \chi|E|^2$. In particular, a graded metallic thin film which dielectric permittivity is anisotropic in the parallel and perpendicular directions is considered. The permittivity in parallel direction is described by the graded Drude model and the permittivity in the perpendicular direction is described by epsilon-near-zero (ENZ) metamaterial. For ENZ metamaterial, the local electric field is enhanced such that $\chi|E|^2 \sim \epsilon$. As a result, the permittivity of ENZ metamaterial can be tuned by the optical Kerr effect. The dispersion relation and the electric field distribution are also examined in the quasi-static condition. By varying the intensity of the incident electric field, the dispersion relation can be switched from elliptical to hyperbolic which allow us to control light prorogation. Furthermore, the implication of the switching from the elliptical to hyperbolic dispersion on the Goos-Hänchen shift will be studied.

2:42PM C22.00002 ABSTRACT WITHDRAWN –

2:54PM C22.00003 Nonlinear Propagation in Fishnet Metamaterials , HAIM SUCHOWSKI, KEVIN O'BRIEN, ZI JING WONG, XIAOBO YIN, XIANG ZHANG, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley, California 94720, USA — We present experimental and theoretical investigations of four-wave mixing in negative index metamaterials at optical frequencies with the goal of demonstrating a phase matched backward wave. The nonlinear propagation in thick fishnet structures are examined, in order to show an experimental observation of backward nonlinear optical generation in negative refractive index materials. We have fabricated a fishnet metamaterial with a negative refractive index in the near infrared and have measured its index using spectrally and spatially resolved interferometry. An infrared four wave mixing process was chosen to ensure that the linear properties of the fishnet can be treated with effective medium theory. The signal and idler are obtained from two optical parametric oscillators driven by synchronized femtosecond lasers. We find that with a counter-propagating pump and signal one can obtain perfect phase matching for the backward propagating idler and a large enough phase mismatch to suppress the forward propagating idler. Our efforts towards an experimental demonstration of nonlinear phase matching in negative index optical metamaterials will be discussed.

3:06PM C22.00004 Metagratings for Diffraction Based, Compact, Holographic Imaging , SANDEEP INAMPUDI, VIKTOR A. PODOLSKIY, University of Massachusetts Lowell, MULTISCALE ELECTROMAGNETICS GROUP TEAM — Recent developments in semiconductor technology brought to life a new generation of highly-compact visible-frequency cameras. Unfortunately, straight forward extension of this progress to low-frequency domains (such as mid-IR imaging) is impossible since the pixel size at these frequencies is limited by free-space diffraction limit. Here we present an approach to realize highly-compact imaging systems at lower frequencies. Our approach takes advantage of high refractive index of materials commonly utilized in semiconductor detectors of mid-IR radiation, accompanied by metagratings, structures with engineered diffraction properties, to achieve a 10-fold reduction in the pixel size. In contrast to conventional refraction-based imaging, the approach essentially produces a digital hologram – a 2D projection of the 3D optical field, enabling a post-imaging "refocusing" of the picture. The perspectives of numerical recovery of the optical field and the stability of such recovery are discussed.

3:18PM C22.00005 Multiple-band transmission in an acoustic metamaterial , RU-WEN PENG, DONG-XIANG QI, REN-HAO FAN, Nanjing University, XIAN-RONG HUANG, Argonne National Laboratory, MING-HUI LU, XU NI, QING HU, MU WANG, Nanjing University, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES, NANJING UNIVERSITY COLLABORATION, ADVANCED PHOTON SOURCE, ARGONNE NATIONAL LABORATORY COLLABORATION — We demonstrate that acoustic waves can achieve extremely flat transmission through a metallic grating under oblique incidence within multiple frequency bands separated by Wood's anomalies. At the low-frequency band, the transmission of acoustic wave is independent of the frequency and presents a flat curve with the transmission efficiency reaching about 100%; while at high-frequency bands, the transmission decreases to be lower flat curves due to the diffraction effect. The transmission efficiency is insensitive to the thickness of the grating. This phenomenon is verified by experiments, numerical simulations, and an analytical model. The broadband high transmission is attributed to the acoustic impedance matching between the air and the grating. This research may open up a field for various potential applications of acoustic gratings, including broadband sonic imaging and screening, grating interferometry, and antireflection cloaking. References: D. X. Qi, R. H. Fan, R. W. Peng et al., Appl. Phys. Lett. 101, 061912 (2012); and R. H. Fan, R. W. Peng, X. R. Huang et al., Adv. Mater. 24, 1980 (2012).

3:30PM C22.00006 Two-Dimensional Control over Gradient Index in a VO_2 Memory Metamaterial , MICHAEL GOLDFLAM, University of California San Diego, TOM DRISCOLL, UCSD and Duke University, DANIEL BARNAS, University of California San Diego, MATTHEW ROYAL, TALMAGE TYLER, NAN JOKERST, DAVID SMITH, Duke University, GIWAN SEO, University of Science and Technology, BONG-JUN KIM, ETRI, HYUN-TAK KIM, ETRI and UST, DIMITRI BASOV, University of California San Diego — We have demonstrated the creation of spatial gradients in the optical properties of a metamaterial device through tuning of a vanadium dioxide layer that interacts with an array of split ring resonators (SRR). Application of a transient electrical pulse across the metamaterial-VO_2 system leaves persistent changes in the properties of the metamaterial due to the hysteresis of the insulator-to-metal transition in VO_2. Through modification of contact geometry, pulse shape, and pulse duration, we have shown increased control over such devices allowing for independent tuning of individual sections of our hybrid VO_2-SRR device through the application of several transient voltage pulses. The characteristics of the gradients resulting from the voltage pulses were measured using infrared transmission spectroscopy. We observed a 15% variation in the magnitude of transmission with spatial scales on the order of one wavelength at the resonance frequency. Thus we have demonstrated the viability of similar tunable metamaterial devices for uses in communications and beam steering.

3:42PM C22.00007 Beating diffraction limit in an absorptive superlens , MENG XIAO, CHE TING CHAN, the Hong Kong university of Science and Technology — It is well known that a slab with both permittivity and permeability equals -1+iδ can achieve super resolution and its mechanism can be understood with the idea of complementary material. In practice, meta-materials are always absorptive and the absorption sets an upper limit for the image resolution. Here, we study the image formation of stratified complementary slabs in the time domain. Instead of only one slab of super lens, we consider a stack of AB structured complementary slabs, where A is a super lens and B is normal material. We show that the superlens stack can beat the diffraction limit even in the presence of loss if the source has a time-dependent intensity profile. We derived a general analytical expression for the group velocity of an arbitrary k component including evanescent waves near frequency where "complementary" is satisfied and the analytical results can explain the super solution in the presence of loss. And our results shows that, with a Gaussian shaped pulse illumination, the image resolution can be improved by about 45% relative to harmonic illumination for the same system.

3:54PM C22.00008 Lamb Shift in the Near Field of Hyperbolic Metamaterial Half Space[1] , NAI JING DENG, KIN WAH YU, The Chinese University of Hong Kong — Hyperbolic metamaterials give a large magnification of the density of states in a specific frequency ranges, and has motivated various applications in emission lifetime reduction, strong absorption, and extraordinary black body radiation, etc. The boost of vacuum energy, which is proportional to the density of states, is expected in hyperbolic metamaterial. We have studied the Lamb shift in vacuum-hyperbolic-metamterial half spaces and shown the non-trivial role of vacuum energy. In our calculation, the easy-fabricated multilayer structure is employed to generate a hyperbolic dispersion relation. The spectrum of hydrogen atoms is calculated with a perturbation method after quantizing the half spaces with a complete mode expansion. It appears that the shift of spectrum is mainly contributed by the terahertz response of materials, which has been well described and predicted in both theories and experiments.

4:06PM C22.00009 Complex Oxide Thin Film Metamaterial Structures for THz applications , D. SHREIBER, U.S. Army Research Laboratory, R. CRAVEY, NASA Langley Research Center, M.W. COLE, U.S. Army Research Laboratory — Metamaterials operating in the frequency range of 0.1-1.5 THz are of a special interest for multiple Army applications such as communications, NDE of materials, and detection of chem./bio hazards. Recently proposed dielectric metamaterials present an intriguing venue for the developments in this field due to their low propagation losses and ease of fabrication. These dielectric metamaterials were implemented in bulk and in thick films. Tunability of ferroelectric complex oxides is achieved by applied bias voltage and constitutes an additional benefit for multiple applications. However, real-life applications require usage of relatively low bias voltage which is achievable only by using a ferroelectric complex oxide thin-film. Although the physical dimensions of the thin film metamaterial structures suggest their usage in IR-optical spectrum, their very high dielectric constant provides a rare opportunity to lower their resonant frequency to the frequency range of interest. This presentation will discuss the opportunities and challenges associated with the metamaterial complex oxide thin film structures including numerical investigations of the resonant frequency shift as a function of the complex oxide thin film dielectric constant and thickness.

4:18PM C22.00010 Analysis of Cyclotron Resonance Spectroscopy in a Landau-quantized 2DEG using Characteristic Matrix Methods[1] , DAVID HILTON, University of Alabama at Birmingham — We develop a new characteristic matrix-based method to analyze cyclotron resonance experiments in high mobility ($\mu_e = 3.7 \times 10^6$ cm^2 V^{-1} s^{-1}) two-dimensional electron gas samples where direct interference between primary and satellite reflections has previously limited the frequency resolution. We use terahertz time-domain spectroscopy to measure the cyclotron resonance and extract the dephasing lifetime where multiple pulses from the substrate with a separation of ~ 15 ps directly interfere in the time-domain. We find a cyclotron dephasing lifetime of 15.1 ± 0.5 ps at 1.5 K and 5.0 ± 0.5 ps at 75 K.

4:30PM C22.00011 Tunable Plasmonic Crystals Induced from a Two Dimensional Electron Gas , GREGORY DYER, Sandia National Laboratories, GREGORY AIZIN, City University of New York, S. JAMES ALLEN, UC Santa Barbara, ALBERT GRINE, DON BETHKE, JOHN RENO, ERIC SHANER, Sandia National Laboratories — A two dimensional electron gas (2DEG) with periodic variation of its screening,[1] geometry,[2] or carrier density[3] provides an electromagnetic medium for the formation of a broadly tunable plasmonic crystal (PC). By using a periodic gate to control the 2DEG density in GaAs/AlGaAs heterostructures, we have induced terahertz (THz) PCs consisting of several bipartite crystal units cells. The PC band structure, Tamm states, and electromagnetically induced transparency phenomena are observed utilizing a gate-controlled defect adjacent to the PC to generate a plasmonic mixing photovoltage. These integrated PCs have potential applications in the areas of frequency selective THz detection, strong light-matter interaction, and planar metamaterials. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000. The work at Sandia National Laboratories was supported by the DOE Office of Basic Energy Sciences. [1]U. Mackens, et. al., Phys. Rev. Lett. **53**, 1485 (1984). [2]V. M. Muravev, et. al., Phys. Rev. Lett. **101**, 216801 (2008). [3]G. C. Dyer, et. al., Phys. Rev. Lett. **109**, 126803 (2012).

4:42PM C22.00012 Controlling Metamaterial Field Enhancement at Terahertz Frequencies , GEORGE KEISER, HUSEYIN SEREN, XIN ZHANG, RICHARD AVERITT, Boston University — With the advent of metamaterials has come an unprecedented ability to manipulate and engineer the index of refraction, n, and impedance, Z of materials. Engineering these far field properties has led to exciting developments such as negative index materials, electromagnetic cloaks, and perfect lensing. However, metamaterials can also be used to engineer designer microscopic charge distributions, current distributions, and polarizabilities. For instance, the on-resonance charge distribution in the capacitive gap of a split ring resonator (SRR) creates a localized region of high electric field enhancement that has seen prominent application in recent work. Here, we present a method to tune the magnitude of this resonant electric field enhancement. Via structural manipulation of the coupling between the SRR and a non-resonant closed conducting ring, we are able to increase and decrease the oscillator strength of the SRR and thus the field enhancement in the SRR's capacitive gap. We present numerical simulations and experimental measurements at terahertz frequencies to confirm this result.

4:54PM C22.00013 Characterization of Micromachined Air-lifted Terahertz Antenna Arrays , CHANG LONG, LUYI YAN, CHEOLBOK KIM, University of Florida, DANIEL J. ARENAS, University of North Florida, YONG-KYU YOON, DAVID B. TANNER, University of Florida — We have designed and fabricated micromachined three dimensional (3-D) air-lifted monopole antenna arrays. The air-lifted antenna arrays have been fabricated using high-aspect-ratio epoxy structures defined by ultraviolet (UV) lithography and subsequent metallization by thin film metal sputtering. The uniqueness of this monopole antenna lies in its strong coupling to incident THz waves with E-field perpendicular to the substrate, which is not the case with most substrate-printed antennas. A Bruker 113v FTIR system has been used to characterize the fabricated arrays for both *s*- (E-field perpendicular to the plane of incidence) and *p*- (E-field parallel to the plane of incidence) polarized light over 30-600 cm^{-1}/1-20 THz. We measured monopole antenna arrays with diameters of 5 μm and different heights from 20 μm to 60 μm. Measurement results are compared to resonant frequency calculations and simulations. The results are in good agreement with those of the simulations.

5:06PM C22.00014 Photo-imprinted diffraction gratings for controlling terahertz radiation.[1] , IOANNIS CHATZAKIS, Ames Lab-U.S. DOE, Iowa State Univ. and Material science Stanford Univ, PHILIPPE TASSIN, LIANG LUO, NIAN-HAI SHEN, LEI ZHANG, JIGANG WANG, THOMAS KOSCHNY, Ames Lab-U.S. DOE and Iowa State Univ., COSTAS M. SOUKOULIS, Ames Lab-U.S. DOE, Iowa State Univ. and Found. of Res. and Techn.-Hellas (FORTH) — We investigate the diffraction of terahertz radiation by photo-imprinted conductive periodic structures. The diffraction gratings are created by optically projecting the image of a metal mask on a high-resistivity GaAs substrate, resulting in a periodic structure of photo-excited charge carriers that scatter terahertz waves. Using terahertz time domain spectroscopy, we show that the terahertz transmission spectra depend characteristically on the lattice constant of the photo-imprinted linear gratings and on the polarization state of the incident terahertz wave, but the transmitted radiation does not depend on the duty cycle of the projected gratings. These experimental results, combined with computer simulations of the structure, confirm that the gratings are purely diffraction-based and are not caused by surface modes or quasistatic resonances. We also demonstrate two-dimensional photo-imprinted diffraction gratings. We anticipate that our findings will have significant impact on the development of reconfigurable components for controlling the terahertz radiation.

5:18PM C22.00015 Nonlinear THz Plasmonic Disk Resonators , HUSEYIN SEREN, Boston Univ. Dept. of Mech. Eng., JINGDI ZHANG, GEORGE KEISER, Boston Univ. Dept. of Physics, SCOTT MADDOX, MRC UT-Austin, KEBIN FAN, Boston Univ. Dept. of Mech. Eng., LINGYUE CAO, Boston Univ. Dept. of Physics, SETH BANK, MRC UT-Austin, XIN ZHANG, Boston Univ. Dept. of Mech. Eng., RICHARD AVERITT, Boston Univ. Dept. of Physics — Particle surface plasmons (PPSs) at visible wavelengths continue to be actively investigated with the goal of nanoscale control of light. In contrast, terahertz (THz) surface plasmon experiments are at a nascent stage of investigation. Doped semiconductors with proper carrier density and mobility support THz PSPs. One approach is to utilize thick doped films etched into subwavelength disks. Given the ease of tuning the semiconductor carrier density, THz PSPs are tunable and exhibit interesting nonlinear THz plasmonic effects. We created THz PSP structures using MBE grown 2um thick InAs films with a doping concentration of 1e17cm^{-3} on 500um thick semi-insulating GaAs substrate. We patterned 40um diameter disks with a 60um period by reactive ion etching. Our THz time-domain measurements reveal a resonance at 1.1THz which agrees well with simulation results using a Drude model. A nonlinear response occurs at high THz electric field strengths (>50kV/cm). In particular, we observed a redshift and quenching of the resonance due to impact ionization which resulted in changes in the carrier density and effective mass due to inter-valley scattering.

Session C23 DMP: Focus Session: Dopants and Defects in Semiconductors III 325 - Matt McCluskey, Washington State University

2:30PM C23.00001 Highly Efficient Defect Emission from ZnO:Zn and ZnO:S Powders[1] , HENRY EVERITT, Army Aviation & Missile RD&E Center, and Dept. of Physics, Duke University — Bulk Zinc Oxide (ZnO) is a wide band gap semiconductor with an ultraviolet direct band gap energy of 3.4 eV and a broad, defect-related visible wavelength emission band centered near 2 eV. We have shown that the external quantum efficiency can exceed 50% for this nearly white emission band that closely matches the human dark-adapted visual response. To explore the potential of ZnO as a rare earth-free white light phosphor, we investigated the mechanism of efficient defect emission in three types of ZnO powders: unannealed, annealed, and sulfur-doped. Annealing and sulfur-doping of ZnO greatly increase the strength of defect emission while suppressing the UV band edge emission. Continuous wave and ultrafast one- and two-photon excitation spectroscopy are used to examine the defect emission mechanism. Low temperature photoluminescence (PL) and PL excitation (PLE) spectra were measured for all three compounds, and it was found that bound excitons mediate the defect emission. Temperature-dependent PLE spectra for the defect and band edge emission were measured to estimate trapping and activation energies of the bound excitons and clarify the role they play in the defect emission. Time-resolved techniques were used to ascertain the role of exciton diffusion, the effects of reabsorption, and the spatial distributions of radiative and non-radiative traps. In unannealed ZnO we find that defect emission is suppressed and UV band edge emission is inefficient ($< 2\%$) because of reabsorption and non-radiative recombination due to a high density of non-radiative bulk traps. By annealing ZnO, bulk trap densities are reduced, and a high density of defects responsible for the broad visible emission are created near the surface. Interestingly, nearly identical PLE spectra are found for both the band edge and the defect emission, one of many indications that the defect emission is deeply connected to bound excitons. Quantum efficiency, also measured as a function of excitation wavelength, closely mirrors the PLE spectra for both emission bands. Sulfur-doped ZnO exhibits additional PLE and X-ray features indicative of a ZnS-rich surface shell that correlates with even more efficient defect emission. The results presented here offer hope that engineering defects in ZnO materials may significantly improve the quantum efficiency for white light phosphor applications.

3:06PM C23.00002 Optical and Magnetic Resonance Studies of Na-Diffused ZnO Bulk Single Crystals , E.R. GLASER, N.Y. GARCES, Naval Research Laboratory, N.S. PARMAR, K.G. LYNN, Washington State U. — Photoluminescence (PL) and optically-detected magnetic resonance (ODMR) at 24 GHz were performed on bulk ZnO crystals after diffusion of Na impurities that were explored as an alternate doping source for p-type conductivity. PL at 2K revealed strong bandedge excitonic recombination at 3.361 eV and a broad "orange" PL band at 2.17 eV with FWHM of $\sim$0.5 eV. This "orange" emission is very similar to that reported previously[1] from thermoluminescence measurements of intentionally Na-doped bulk ZnO and, thus, strongly suggests the incorporation and activation of the Na-diffused impurities. ODMR performed on this "orange" PL revealed two signals. The first was a sharp feature with g-value of $\sim$1.96 and is a well-known "fingerprint" of shallow donors in ZnO. The second signal consisted of a pair of lines with an intensity ratio of $\sim$3:1 and with g-tensors ($g_{\parallel}$,$g_{\perp}\sim$2.008-2.029) very similar to ESR signals attributed previously[2] to holes bound to Na impurities located at the axial and non-axial Zn host lattice sites in Na-doped ZnO. Thus, the "orange" PL can be tentatively assigned to radiative recombination between residual shallow donors and deep Na-related hole traps.

3:18PM C23.00003 Quantum Emission from Defects in ZnO , N.R. JUNGWIRTH, E.R. MACQUARRIE, H.S. CHANG, G.D. FUCHS, Cornell University — Single defects in wide bandgap semiconductors, such as nitrogen-vacancy centers in diamond, are promising candidates for solid state qubits and single photon sources. Additionally, single defect studies provide an opportunity to probe properties and dynamics that are washed out of ensemble measurements. Despite the wealth of available semiconducting hosts, investigations of isolated defects in semiconductors other than diamond are limited. Here we present confocal photoluminescence measurements of ZnO nanocrystals that are excited with below bandgap light to selectively address individual deep levels. In addition to wavelength-resolved and time-resolved photoluminescence measurements, we report photon anti-bunching that is consistent with quantum emission from isolated defects. These measurements, made at the single and few defect level, enable insight into long-standing questions that surround defect emission in ZnO.

3:30PM C23.00004 Rare-earth doped Si-rich ZnO for multiband near-infrared light emitting devices , EMANUELE FRANCESCO PECORA, THOMAS IAN MURPHY, LUCA DAL NEGRO, Boston University — Transparent Conductive Oxides (TCOs) are a broad class of organic and inorganic materials exhibiting both optical transparency and electrical conductivity simultaneously. TCOs are utilized as top-con tact passive layers in a number of optoelectronic devices, including flat panel displays and solar cells. Recently, they are also attracting considerable attention as an active platform for a wide range of novel device applications. Zinc oxide (ZnO) is the most promising candidate for optoelectronic integration due to its low cost and Si compatibility. Moreover, it is a biocompatible material and possibly biodegradable. We fabricated rare earth-doped Si-rich ZnO thin films through magnetron sputtering and we investigate their near-infrared emission properties under both optical and electrical injection. Er and Nd efficient (3ms RT lifetime) radiative transitions were simultaneously activated due to energy transfer via the ZnO direct bandgap and its luminescent defect centers. Moreover, by incorporating Si atoms, we demonstrate Si-mediated enhancement of light emission in Er-doped ZnO, and electroluminescence. We fabricated a proof-of-concept 1.55μm-electroluminescent device with record low turn-on voltage ($<$1.5V) in Er-doped Si-rich ZnO at room temperature. These results pave the way to novel Si-compatible light emitters that leverage the optically transparent and electrically conductive ZnO matrix for multiband near-IR telecom and bio-compatible applications.

3:42PM C23.00005 Synthesis of ZnO:Ge Thin Films via Plasma Gas Condensation , ABDULLAH CEYLAN, JANAN ALI, SADAN OZCAN, SNTG Lab. Physics Eng. Dept. Hacettepe Univ. 06800, Beytepe, Ankara, Turkey — we introduce a new method for the synthesis of Ge nanoparticle embedded ZnO thin films that are considered to be a potential candidate for photovoltaic applications. As opposed to current techniques, for the independent preparation of Ge nanoparticles, Cluster Deposition Source (CDS) utilising gas condensation of sputtered Ge atoms is used. For the synthesis of ZnO thin film host material conventional sputtering is employed. In the proposed technique independently synthesized Ge nanoparticles and ZnO thin films are combined into a composite structure on Si. XRD patterns of the samples have revealed that Ge nanoparticles preferentially settle on (113) planes on top of the (002) oriented ZnO layer. It is realized that Ge nanoparticles with sizes ranging from 16 nm to 20 nm could be embedded into a well-defined ZnO matrix. In fact, TEM studies performed on Ge nanoparticles captured on a Cu grids have manifested that Ge reach to ZnO matrix as clusters composed of particles with sizes of about 7-8 nm and then eventually grow larger due to substrate heating implemented during capping layer deposition. Optical absorption measurements have revealed that Ge nanoparticle inclusion lead to an additional absorption edge at about 2.75 eV along with 3.17 eV edge resulting from ZnO host.

3:54PM C23.00006 Identification of a N-related shallow acceptor and related EPR center in ZnO: N2 on Zn site[1] , WALTER R.L. LAMBRECHT[2], CWRU, ADISAK BOONCHUN, NIMS, Tsukuba, Japan and Kasetsart Univ., Bangkok — While the deep level of N_O makes it unsuitable for p-type doping of ZnO, a shallow level at about 165$\pm$40 meV above the VBM related to N is known to exist in ZnO (Zeuner et al. 2002). Here we show that a N_2 molecule on the Zn site behaves as a shallow acceptor. First-principles calculations show that when N_2 is placed on a Zn site, two electrons are removed from the σ_g^+ HOMO. The molecular levels line up with the ZnO band strucure in such a way that the σ_g^+ level forms a resonance near the VBM. In contrast, for N_2 on the O-site, two extra electrons occupy the π_g LUMO of the N_2 molecule and form a donor level. The 0/- transition level of the acceptor is found at $\sim$0.2 eV above the VBM. When singly occupied the defect corresponds to a N_2^+ radical. We show that the g-factor, calculated within a simple tight-binding model, of this radical agrees better with an observed EPR center by Garces et al. (2003) than the N_2^- radical. The σ_g nature of the defect wavefunction for N_2 on Zn is consistent with a significant isotropic hyperfine interaction, while the π_g character of N_2 on O is not. The lower value of A_{iso} compared to the isolated molecule is consistent with the shallow nature of the defect.

4:06PM C23.00007 Quantum Monte Carlo calculation of point defect thermal and optical ionization levels: application to magnesium oxide and zinc oxide , ELIF ERTEKIN, LUCAS WAGNER, University of Illinois, JEFFREY GROSSMAN, Massachusetts Institute of Technology — From electronics to optoelectronics to photovoltaics, point defects influence and dominate the properties of semiconducting materials. Quantitative descriptions of the effect of point defects on electronic, optical, and transport properties are critical to enabling point-defect engineering for materials design. However, accurate prediction of point-defect energetics, thermal ionization energies, and optical transition energies from first principles remains a challenge. We present an approach to calculation of point defect optical and thermal ionization energies based on the highly accurate quantum Monte Carlo methods, and demonstrate it for the oxygen vacancy in the binary ionic compound magnesium oxide and the substitutional nitrogen impurity in zinc oxide. The use of quantum Monte Carlo, an inherently many–body theory that directly treats electron correlation, offers many improvements: it can help overcome the band gap problem in density functional theory and obviate the need for ad-hoc corrections. Our computed optical and thermal ionization energies are in excellent agreement with experimental and/or other high-accuracy results.

4:18PM C23.00008 ABSTRACT WITHDRAWN –

4:30PM C23.00009 Non-stoichiometric Mn doped ZnO clusters: First principles calculations[1] , SACHIN P. NANAVATI, SHAILAJA MAHAMUNI, S.V. GHAISAS, University of Pune, India, VIJAY KUMAR, Dr. Vijay Kumar Foundation, Gurgaon, India — It has been reported that cage like hollow clusters of $(ZnO)_n$ with n = 12 & 34 are stable and hence $magic$. Doping Mn impurity in ZnO (ZnO:Mn) clusters is a well studied problem. In most of the studies, single Mn doping has been achieved by substituting it on a surface Zn site, leading to a stoichiometric configuration of $Zn_{n-1}MnO_n$ and a large magnetic moment of 5 μ_B. However, we show that using first principles methods, Mn doping would lead to O rich, non-stoichiometric clusters with significantly reduced magnetic moment. Specifically, we show that clusters of configuration $Zn_{12}MnO_{15}$ and $Zn_{34}MnO_{37}$, obtained when Mn is substituted in $(ZnO)_n$ (n = 13 & 35) cages, become magic. The magnetic moments in these clusters is reduced to 1 μ_B. These clusters can also be considered as a composite structure where a MnO_x (x = 1 to 4) molecule is attached to ZnO_n (n = 12 & 34) cages from outside.[2] We believe that these results would have important implications for the understanding of magnetism in ZnO:Mn nanostructures as well as thin films, for which recent experiments suggest mixed and higher oxidation states of Mn, $viz.$, Mn^{+3} and Mn^{+4}.

4:42PM C23.00010 Theoretical study of preferred dopants for n-type transparent conducting oxides , SU-HUAI WEI, National Renwable Energy Laboratory, USA, CHONG LI, JINGBO LI, Institute of Semiconductor Physics, CAS, China, WANJIAN YIN, YANFA YAN, Department of Physics, University of Toledo, USA — Traditionally, it is believed that the conduction band edges of d^0 or d^{10} oxides are derived mostly from cation states, thus substitutional doping on anion sites is expected to cause less perturbation and produce shallow donor levels in these materials. Using first-principles calculations, we show that although this paradigm is applicable for more covalent oxides such as SnO_2 where F_O is a better n-type dopant than Sb_{Sn}, for more ionic oxides such as ZnO, the conduction band edge actually contains a considerable amount of O s orbitals, thus F_O in ZnO causes larger perturbation and consequently produces deeper donor levels than cation site doping such as Al_{Zn}. This observation can be explained by coupling of cation state with high lying oxygen orbitals. The origin of the preferred n-type dopability of oxides, the potential of oxygen vacancy as n-type dopant, and the selection of chemical potential for n-type doping will also be discussed.

4:54PM C23.00011 Strong enhancement of the luminescence decay time of isoelectronic centers in GaP:N at low temperatures , PHILIPPE ST-JEAN, GABRIEL ETHIER-MAJCHER, ALARIC BERGERON, SEBASTIEN FRANCOEUR, Ecole Polytechnique de Montreal — Using time-resolved photoluminescence, the recombination dynamics of excitonic states bound to isoelectronic centers formed by either one or a pair of nitrogen atoms in GaP is investigated as a function of internuclear distance and temperature. Depending on their symmetry, centers formed by a pair of atoms exhibit several optical transitions that are, according to the excitonic state involved, either linearly polarized or unpolarized. At 4 K, for all nitrogen pairs studied, relatively long lifetimes approaching 1 μs are observed. Interestingly, these lifetimes vary considerably between excitonic states and ranges from 500 to 800 ns. This strong variation decreases with temperature, leading to similar lifetimes. Furthermore, as the temperature is increased to 30 K, all lifetimes decrease by about an order of magnitude, down to 60-90 ns, as previously reported. A thermodynamic model of the evolution of excitonic populations shows that a thermally activated process of about 2.5 meV characterizes this temperature behavior. This activation energy corresponds to an inter-level transfer between excitonic states. These findings enhance our understanding of the dynamics of carriers bound to isoelectronic centers, which are promising candidates for atomic-sized charge storing device.

5:06PM C23.00012 Mechanism for conduction in polycrystalline p-type indium oxide films[1] , JOLANTA STANKIEWICZ, ICMA, CSIC-Universidad de Zaragoza, FRANCISCO VILLUENDAS, Departamento de Fisica Aplicada, Universidad de Zaragoza, Spain — We report (i)- results from ac impedance measurements obtained for intrinsic indium oxide films, grown under O_2-rich conditions, (ii)- current-voltage (I-V) curves for p-n homojunctions fabricated by sequential growth of a 200 nm thick p–type In_2O_3 layer on a 400 nm thick n–type In_2O_3, and (iii)- capacitance-voltage (C-V) curves for these junctions. Impedance as well as I-V and C-V measurements were performed under UV irradiation and in darkness. We find two distinct contributions to the ac conductivity. One of them is brought about by grain boundaries, and the other one by inversion layers, which are on grain surfaces. In addition, we have found that photocurrents relax extremely slowly in these films. All of this fits consistently within a model in which mobile holes in inversion layers are responsible for p-type dc conductivity in intrinsic indium oxide films grown under O_2-rich conditions. Such mechanism might be important in other polycrystalline thin films which have a large number of oxidizing defects at grain boundaries.

Session C24 GSCCM DCOMP DMP: Focus Session: Materials in Extremes: Chemistry under Extreme Conditions 326 - Jonathan Crowhurst, Livermore National Laboratory

2:30PM C24.00001 Meso-scale Simulations and Instrumented Experiments in Metastable Intermolecular Composites , NARESH THADHANI, Georgia Institute of Technology — Impact initiation of reactions in various aluminum-based intermolecular composites in the form of powder mixture compacts and cold-rolled laminates are being investigated using instrumented gas-gun impact experiments under conditions of uniaxial-strain and uniaxial-stress loading. Time-resolved stress and particle velocity measurements as well as high-speed imaging are used for monitoring the deformation and reaction states to obtain evidence of reaction based on changes in compressibility and shock-velocity, as well as via direct light emission. Meso-scale numerical simulations with CTH multimaterial hydrocode are also performed on actual (imported) micrographs. The simulations allow qualitative and quantitative probing of the local configurational changes and their effects on impact-initiated reaction mechanisms, following validation of macroscopic properties by correlations with experiments. The heterogeneous nature of wave-propagation through reactants of dissimilar elastic and plastic properties and morphological characteristics, produce effects that give rise to turbulent flow, vortex formation, and dispersion of reactants across large distances. Understanding of these processes as a function of mathematically represented constituent configuration and state of stress/strain is essential for designing energetic/reactive materials systems with tunable energy release characteristics.

3:06PM C24.00002 Polymerization in Substituted Acetylenes: A Comparison between Static, Medium-Strain Rate, and Shock Compression Studies. , RAJA CHELLAPPA, DANA DATTELBAUM, NENAD VELISAVLJEVIC, Los Alamos National Laboratory, HANNS-PETER LIERMANN, Extreme Conditions Beamline, PETRA III, DESY — Fast timescale of reactions occurring during shock compression create significant diagnostics challenges to fully quantify the mechanisms involved. Static compression provides a complementary route to investigate the equilibrium phase space and metastable intermediates during high pressure chemistry. Intermediate strain rate compression (0.001/s or higher) with time-resolved probes is a novel way to extract reaction kinetics and underlying pathways. In this study, we present our results from high pressure in situ synchrotron x-ray diffraction (XRD) and infrared (IR) spectroscopy studies on substituted acetylenes: tert-butyl acetylene [TBA: (CH3)3-C≡CH] and ethynyl trimethylsilane [ETMS: (CH3)3-SiC≡CH]. We observed that the onset pressure of chemical reactions at room temperature (C≡C → C=C polymerization) in these compounds was typically higher in static compression (TBA: 11 GPa and ETMS: 26 GPa) when compared to shock input pressures (TBA: 6.1 GPa and ETMS: 6.6 GPa). Expectedly, thermal effects during heating drive the threshold pressure were close to shock conditions as observed during the high temperature measurements. Under compression at medium strain rate (1 GPa/s or higher), a clear progression of the chemical reaction was observed via time-resolved XRD patterns obtained at 0.5s intervals. It is noted that the reaction products were visually observed to be glassy and recovered to ambient conditions, remaining stable with no degradation.

3:18PM C24.00003 Cellular Structure and Oscillating Behavior of PBX Detonations[1] , IGOR PLAKSIN, RICARDO MENDES, ADAI/LEDAP - University of Coimbra, PORTUGAL — Efforts are aimed on bridging experimental and theoretical studies of localizations/instabilities manifested in detonation reaction zone (DRZ) at micro-, meso-, and macro-scale. In molecular level, the theoretical/computational studies of detonation (RDX, HMX) show: reaction localizations onset/growth is caused by kinetic nonequilibrium stimulated by different levels of activation barriers/reaction energies at bonds dissociation processes (C-NH2, C-NO2, C=C). At micro- and meso-scale levels, leading role of kinetic nonequilibrium in reaction localizations onset was established in experiments with single beta-HMX crystals-in-binder subjected to 20 GPa-shock and PBX detonation. Reaction localizations and further ejecta formation were spatially resolved by 96-channel optical analyzer at simultaneous recording reaction light and stress field around crystal. Spatially-resolved measurements reveal fundamental role of shear-strain in triggering initiation chemistry. At macro-scale level, formation of the cell-structures and oscillating detonation regimes revealed in HMX- and RDX-based PBXs at wide variation of grain-sizes, wt. % filler/binder, residual micro-voids and binder nature. Emphasizes placed on effect of DRZ-induced radiation upon oscillating regimes of detonation front motion.

[1]This work was supported by the Office of Naval Research under the ONR and ONR Global Grants N00014-12-1-0477 and N62909-12-1-7131 with Drs. Clifford Bedford and Shawn Thorne Program Managers.

3:30PM C24.00004 Ultrafast shock induced chemistry in hydrogen peroxide , MICHAEL ARMSTRONG, JOSEPH ZAUG, NIR GOLDMAN, I-FENG KUO, JONATHAN CROWHURST, W. MICHAEL HOWARD, JEFFREY CARTER, MICHAELE KASHGARIAN, JOHN CHESSER, TROY BARBEE, SORIN BASTEA, Lawrence Livermore National Laboratory — Although strong compression waves have been used to study the equilibrium high pressure and temperature properties of materials for more than half a century, the study of ultrafast strain rate dependent material transformations, while promising, is only beginning to be fully explored. Shock waves can change the thermodynamic state of a material over a picosecond time scale, i.e. faster than the time scale of quasi-equilibrium reaction kinetics for many reactive systems. This fundamental property of shock compression suggests the possibility of selecting reaction paths via modulation of applied compression waves on a time scale that is faster than the time scale of reaction kinetics. Here we present experiments and thermochemical and molecular dynamics simulations on a model system, hydrogen peroxide, which demonstrate that the applied strain rate can be used alongside the pressure and temperature to control reactivity in bulk matter, thus enabling the exploration of otherwise inaccessible chemical reaction paths.

3:42PM C24.00005 A possible crystal defect mediated mechanism governing energy release in solid organic secondary explosives , BRYAN HENSON, LAURA SMILOWITZ, Los Alamos National Laboratory — Work has been ongoing in our group for several years to produce a global chemistry model of thermal ignition for the solid organic secondary explosive octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX) valid over the entire temperature range of energetic response from thermal ignition to detonation. We have made considerable progress recently, resulting in the first broadly accurate model of this type for HMX. We have also recently provided the first theory of the phenomenon of melt acceleration in the thermal decomposition which indicates a universal mechanism applicable to this entire class of materials. The success of these models derives from the kinetic rate equations used, which are based upon rates activated by energies of vaporization and sublimation. The equations can be reduced to dimensionless form, yielding melt accelerated rates of thermal decomposition, ignition and detonation which are functions of two rate constants, one proportional to the liquid activity and another that can be interpreted as the simultaneous occupation of two defect states of the crystal. In this reduced form, data from a number of secondary explosives may be superposed on common curves. In this talk we explore the possibility that the underlying mechanism responsible for this behavior is linked to the equilibrium population of a crystal defect described by a vacancy in contact with local disorder.

3:54PM C24.00006 Fragmentation of explosively driven Al-W granular composite rings[1] , KARL OLNEY, PO-HSUN CHIU, University of California, San Diego, CHRIS BRAITHWAITE, ANDREW JARDINE, ADAM COLLINS, Cavindish Laboratory, Cambridge, DAVID BENSON, VITALI NESTERENKO, University of California, San Diego — Al oxidation has a chemical potential nearly 5 times that of traditional high explosives, however, the oxidation rate scales with the Al particle size. To oxidize on a time scale of $\sim$1ms, Al particle size needs to be on the order of 20microns. Continuum theory and experiments of homogeneous materials show that fragments generated under typical loading conditions have much larger sizes (order 1-10mm). Using a highly heterogeneous material with constituents that have drastically different shock impedances (such as Al and W) provides additional mesoscale mechanisms that allow for further pulverization of the material into smaller fragments. Explosively driven expanding ring experiments were conducted on Al-W granular composite rings and recovered fragments showed a significant reduction in the fragment size compared to a homogeneous sample. Examination of the fragments under SEM showed a propensity for fragments to be composed of a cluster of Al and W particles with little plastic deformation in the interior Al. Hydrocode simulations were conducted to gain an insight into this clustering behavior. Understanding of the mesoscale mechanisms may be used to generate mesostructures that could tailor the size of generated fragments based on the loading conditions.

4:06PM C24.00007 Dynamic Behaviors of Two PBX Explosives under Ramp Wave Loading , GUIJI WANG, JINTAO CAI, Institute of Fluid Physics, YANHONG ZHAO, HAIFENG SONG, Beijing Institute of Applied Physics and Computation Mathematics — By means of the magnetic force produced by pulsed power generator CQ-1.5 and CQ-4, two PBX explosives are dynamically characterized under ramp wave loadings from several GPa to 10 GPa in experiments and calculations. The experimental and calculated results show that the PBX explosives exhibit visco-elastic or elastic effects, and the Mie-Grüneisen EOS can't well reflect the dynamic nature of PBX-1 and PBX-2 explosives at lower pressure of below 1 GPa. And it can describe their dynamic behaviors well above 1GPa. In this paper, the SG constitutive model is also used to describe this property of PBX9501, which shows good agreement with the experimental results and those of calculated from visco-elastic model by Baer.

4:18PM C24.00008 Novel energetic materials for quantum optical initiation , ROBERT SCHARFF, MARGO GREENFIELD, SHAWN MCGRANE, DAVID MOORE, DAVID CHAVEZ, SERGEI TRETIAK, TAMMIE NELSON, Los Alamos National Laboratory — The development of new photoactive materials, which optically initiate through quantum controlled photochemical dynamics, would provide a transformational advancement in the laser-based ignition of energetic materials. Ideal materials should have low initiation thresholds for specific optical pathways while simultaneously having high initiation thresholds for all other conventional stimuli. Optical control can only be effective in newly designed materials that are synthesized to take advantage of such control; consequently, quantum control of optical initiation requires a thorough understanding of the excited state molecular dynamics that leads to photochemical decomposition. To date, our efforts have focused on making new materials with energetic optical chromophores and validation of their non-linear optical response properties through experiment and simulation.

4:30PM C24.00009 Molecular dynamics simulation of spinning detonation in energetic AB material , VASILY ZHAKHOVSKY, MIKALAI BUDZEVICH, AARON LANDERVILLE, IVAN OLEYNIK, University of South FLorida, CARTER WHITE, Naval Research Laboratory — Spinning detonation-wave structure is observed in molecular dynamics simulation of a solid energetic material (EM) confined in the round tube with smooth walls. The EM is represented by a modified AB model with adjustable barrier height for exothermic reaction AB+B $\rightarrow$ A+BB, which allows us to study the evolution of detonation-wave structure produced by instabilities of the planar detonation front as a function of physico-chemical properties of the EM material, including its thermochemistry and reactive equation of state. The planar detonation wave in a tube of relatively small radius evlolves into an unstable pulsating detonation through the development of longitudinal perturbations, which can later lead to a collapse of the detonation wave. However, as the tube radius is increased, the detonation wave structure is stabilized by a development of a single-headed spinning detonation having an unusual four-wave configuration. Further increase of the tube radius results in a multi-headed detonation structure with turbulent-like distributions of pressure and other physical variables at the front, similar to that observed in gases.

4:42PM C24.00010 Quantum mechanical simulations of condensed-phase decomposition dynamics in molten RDX[1] , IGOR SCHWEIGERT, US Naval Research Laboratory — A reaction model for condensed-phase decomposition of RDX under pressures up to several GPa is needed to support mesoscale simulations of the energetic material's sensitivity to thermal and shock loading. A prerequisite to developing such a model is the identification of the chemical pathways that control the rate of the initial dissociation and the subsequent decomposition of the dissociation products. We use quantum mechanics based molecular dynamics simulations to follow the decomposition dynamics under high-pressure conditions and to identify the reaction mechanisms. This presentation will describe current applications to liquid-phase decomposition of molten RDX.

4:54PM C24.00011 Formation of 2D Graphene-like Structures in Reacting Carbon-Rich Energetic Materials , RIAD MANAA, LAURENCE FRIED, Lawrence Livermore National Laboratory — The late stages of extreme reactivity in carbon-rich energetic materials such as 1,3,5-triamino-2,4,6-trinitrobenzene (TATB) are characterized by the slow evolution of carbon to different phases. Slow growth from clusters to graphite and even nano-diamonds have been noted experimentally in detonating TATB. We conducted long-time scale, constant volume-temperature molecular dynamics simulations on pre-shocked TATB crystals for over 3 nanoseconds. Using the reactive force-field Reaxff, and at conditions of temperatures of 2500 and 3000 K, and a pressure of 16 $\sim$ 20 GPa, we discover the formation of 2D graphene-like structures of predominantly carbon, with very low heterogeneity of oxygen and nitrogen at the edges. While these simulations have enabled us to track the reactivity of TATB well into the formation of several stable gas products, such as H_2O, N_2, and CO_2, the formation of graphene-like structures and its slow evolution into final graphite and diamond like structures may finally explain the very low reactivity of TATB, as evidenced in its large reaction zone.

5:06PM C24.00012 A Generalized Reduced Model of Uniform and Self-Propagating Reactions in Reactive Nanolaminates , LEEN ALAWIEH, Johns Hopkins University, OMAR KNIO, Duke University; Johns Hopkins University, TIMOTHY WEIHS, Johns Hopkins University — Reactive nanolaminates are comprised of alternating layers of materials that react exothermically. Self-propagating reaction fronts, traveling at speeds that can exceed 10m/s, can be initiated in these materials using an external heat source. The wide range of length and time scales involved in such reactions presents a typical modeling challenge due to the inherent interplay of the different scales in the underlying dynamics and the eventual end-product. In this presentation, we will discuss the development of a reduced reaction model for Ni/Al nanolaminates. The model incorporates a generalized, anisotropic description of thermal transport that also accounts for the dependence of thermal conductivity on composition and temperature. A generalized description of intermixing is also developed, that incorporates information derived from disparate experimental observations, and molecular dynamics (MD) computations. Using insights gained from MD computations, intermixing is described using a simplified, temperature-dependent composite diffusivity relation that enables us to reproduce measurements of low-temperature ignition, homogeneous reactions at intermediate temperatures, as well as the dependence of reaction fronts on micro-structural parameters.

5:18PM C24.00013 Ultrafast Vibrational Spectroscopy of Shock Compressed and Flash-Heated Single Molecular Layers[1] , CHRISTOPHER BERG, ALEXEI LAGUTCHEV[2], DANA DLOTT, University of Illinois at Urbana-Champaign — We report the shock compression and flash-heating of single molecular layers on metallic substrates probed with an ultrafast nonlinear coherent vibrational spectroscopy, vibrational sum frequency generation (SFG). Laser-driven shock compression and flash-heating resulted in pressures of a few GPa and temperatures greater than 500 K, respectively. Due to shock velocities of a few nm/ps, single molecular layers allowed picosecond time resolution of shock loading. Monolayers further allowed the measurement of heat transport from the monolayer-metal anchor point to the monolayer's terminus. SFG spectroscopy was utilized due to its sufficient monolayer sensitivity. Shock loading dynamics were analyzed with the help of static high pressure measurements in a diamond anvil cell, and flash-heating results were compared with simulations.[3,4]

Session C25 GQI: Superconducting Qubits: 3D Architecture 327 - David Schuster, University of Chicago

2:30PM C25.00001 Approaching 10 Milliseconds for Aluminum Cavities in the Quantum Regime , MATTHEW REAGOR, HANHEE PAIK, GIANLUIGI CATELANI, LUYAN SUN, CHRISTOPHER AXELINE, TERESA BRECHT, JACOB BLUMOFF, LUIGI FRUNZIO, LEONID GLAZMAN, ROBERT SCHOELKOPF, Department of Physics and Applied Physics, Yale University — One of the most promising solid state quantum computing architectures couples superconducting qubits to microwave resonators (circuit QED), a system in which three-dimensional microwave cavities have become a valuable resource. Participation-ratio calculations predict at least four orders of magnitude longer lifetimes in 3D cavities than their planar resonator counterparts with equal material losses. Motivated by this principle, we report multiple superconducting aluminum cavities with lifetimes on the order of 10ms at single photon power and millikelvin temperatures. We also present details on extracting the materials properties and the noise performance of a long lived superconducting cavity resonator, including bounds on the intrinsic dephasing time (T_ϕ) of such a resource.

2:42PM C25.00002 Materials Effects in 3D-Cavity Transmon Qubits , DANIELA F. BOGORIN, MATTHEW WARE, STEPHEN SOROKANICH, B.L.T. PLOURDE, Syracuse University, Physics Department — Recent experiments have demonstrated significant increases in the coherence of superconducting transmon qubits coupled to three-dimensional microwave cavities. We are investigating the effects of different materials for forming such cavities, as well as various surface treatments of the cavity walls, including electropolishing and electroplating. In addition, we are exploring the influence of the superconducting material that forms the qubit capacitor along with the material that forms the substrate on which the qubit is fabricated.

2:54PM C25.00003 Coherence of Superconducting Whispering Gallery Resonators[1] , ZLATKO MINEV, IOAN POP, DOMINIC KWOK, MICHEL DEVORET, Applied Physics Department, Yale University — Quantum signal processing applications rely on the design of microwave resonators with quality factors at the single photon level exceeding a million. We present a novel on-chip whispering gallery mode resonator formed by two superconducting rings on separate wafers facing each other. The mode energy is principally housed in the lossless vacuum between the rings. We measure internal quality factors of a few million at the single photon level. The superconducting whispering gallery resonator is easily integrable with superconducting qubits. It also constitutes a new tool to characterize thin film material properties.

[1]Work supported by IARPA, ARO, NSF and YINQE.

3:06PM C25.00004 Deterministic creation of Schrodinger cat states in a superconducting waveguide cavity , BRIAN VLASTAKIS, GERHARD KIRCHMAIR, ZAKI LEGHTAS, Yale University Dept. of Applied Physics, SIMON NIGG, Yale University Dept. of Physics, LUIGI FRUNZIO, Yale University Dept. of Applied Physics, STEVEN GIRVIN, Yale University Dept. of Physics, MAZYAR MIRRAHIMI, INRIA Paris-Rocquencourt, ROBERT SCHOELKOPF, Yale University Dept. of Applied Physics — Off-resonant coupling of a superconducting transmon qubit to a three-dimensional waveguide cavity provides a dispersive qubit/cavity interaction much stronger than any decay rates in the system. Using a two-cavity/single-qubit architecture, we utilize this interaction to deterministically map a qubit state to a superposition of coherent states in a cavity (up to a 40 photon separation). By measuring photon-number parity, we perform Wigner tomography that shows the characteristic interference inherent in quantum superpositions, thus confirming the non-classical properties of the cavity state. Furthermore, we extend this method[1] to create multi-component Schrodinger cat states including the four-component compass state. [1] Z. Leghtas et al. Deterministic protocol for mapping a qubit to coherent state superpositions in a cavity. arXiv.org quant-ph 1208.1603 (2012).

3:18PM C25.00005 Tunable 3D cQED: Implementation and Characterization , KEVIN CHOU, MATTHEW REED, NISSIM OFEK, JACOB BLUMOFF, BRIAN VLASTAKIS, GERHARD KIRCHMAIR, Yale University Dept. of Applied Physics, SIMON NIGG, Yale University Dept. of Physics, LUIGI FRUNZIO, Yale University Dept. of Applied Physics, STEVEN GIRVIN, Yale University Dept. of Physics, ROBERT SCHOELKOPF, Yale University Dept. of Applied Physics — Significant progress has recently been made in improving the coherence of superconducting qubits by using the 3D cQED architecture. This current design is static, not allowing for the modulation of couplings and nonlinearities in situ. This limitation may prove to be an obstacle toward scaling this implementation into more complex systems. We present a new architecture which integrates high Q-factor 3D resonators with flux-tunable superconducting transmon qubits. In this talk, we will demonstrate full control over qubit frequency with minimal degradation to qubit and cavity lifetime. This capability allows the rapid and precise control over the system Hamiltonian to choose optimal couplings and nonlinearities as dictated by the experiment.

3:30PM C25.00006 Tunable 3D cQED: Applications to Quantum Optics and Quantum Information , MATTHEW REED, KEVIN CHOU, NISSIM OFEK, JACOB BLUMOFF, BRIAN VLASTAKIS, GERHARD KIRCHMAIR, ZAKI LEGHTAS, Yale University Dept. of Applied Physics, SIMON NIGG, Yale University Dept. of Physics, LUIGI FRUNZIO, Yale University Dept. of Applied Physics, STEVEN GIRVIN, Yale University Dept. of Physics, MAZYAR MIRRAHIMI, INIRA Paris-Rocquencourt, ROBERT SCHOELKOPF, Yale University Dept. of Applied Physics — The ability to control the frequency of a superconducting qubit on nanosecond timescales has been used, among other things, to generate multi-qubit entanglement. The recently developed 3D cQED architecture has yielded dramatic coherence improvements and novel methods of entangling fixed-tuned qubits, but has until now has lacked the ability to control qubit frequencies in situ. Adding this would grant several abilities. First, the coupling of a qubit to the cavity bus could be modulated to control both the inherited nonlinearity and the dispersive shift of the oscillator. Second, controlling the interactions between individual qubits, particularly those coupled to more than one cavity, could be used to shuttle quantum information between subsystems. Third, a small change to the physical implementation could yield efficient individual qubit QND readout or reset. These abilities are readily applicable to demonstrations of hardware-efficient quantum error correction, entanglement distillation between distant pairs of qubits, and teleportation of quantum information. In this talk, we will discuss our recent results toward achieving these capabilities using the tunable 3D cQED architecture introduced previously.

3:42PM C25.00007 Extended coherence times of superconducting transmon qubits[1] , ERIK LUCERO, MATTHIAS STEFFEN, JAY GAMBETTA, DAVID ABRAHAM, ANTONIO CORCOLES, IBM T. J. Watson Research Center, IBM QUANTUM COMPUTING TEAM — As part of the IBM quantum computing effort, we are building on the pioneering work [1] and recent advances [2] on transmon qubits enclosed in three-dimensional cavities ("3D qubits"). To continue the advance of superconducting qubit architectures for surface code implementations it is clear that we must understand what is limiting coherence times and work to mitigate its effects. By leveraging the reduced fabrication requirements (compared to two-dimensional qubits) and full-device electromagnetic simulation, 3D qubits provide an insightful experimental test-bed to help determine the participation of decoherence mechanisms (e.g. materials, surfaces, radiation) in superconducting qubits. We report on coherence times that go beyond those reported recently [2], making 3D qubits a viable architecture for a prototype quantum processor. [1] Paik, et al., Phys Rev. Lett. 107 240501 [2] Rigetti et al., Phys. Rev. B 86, 100506

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324

3:54PM C25.00008 Fluxonium Qubit in a 3D Cavity: Design and Implementation[1] , I.M. POP, K. GEERLINGS, N. MASLUK, A. KAMAL, Applied Physics Department, Yale University, G. CATELANI, Forschungszentrum Juelich, Peter Gruenberg Institut, L. GLAZMAN, M.H. DEVORET, Applied Physics Department, Yale University — We describe the implementation of a fluxonium artificial atom [1] with improved coherence times. Our qubit is inductively coupled to a Josephson junction resonator on a sapphire substrate, placed inside a 3D copper cavity. The keystone of the fluxonium qubit is its superinductance, which consists of an array of 90 Josephson junctions. We describe superinductance design improvements [2] which effectively eliminate spurious phase-slips and raise the self-resonant modes of the superinductance well above the frequency of the qubit. Networks of Josephson junctions will be useful for designing custom symmetries in cQED Hamiltonians.

[1]Work supported by IARPA, ARO, NSF and YINQE.

4:06PM C25.00009 Fluxonium Qubit in a 3D Cavity: Measurement and Analysis[1] , K. GEERLINGS, I.M. POP, N. MASLUK, A. KAMAL, Applied Physics Department, Yale University, G. CATELANI, Forschungszentrum Juelich, Peter Gruenberg Institut, L. GLAZMAN, M.H. DEVORET, Applied Physics Department, Yale University — We present measurements of a fluxonium qubit [1] in a 3D copper cavity. The fluxonium qubit is composed of a Josephson junction shunted by an array of 90 larger Josephson junctions approximating a linear inductor. In a manner similar to transmon qubits, the coherence times of fluxonium in a 3D cavity have increased when compared to on-chip resonator implementations. Additionally, the fluxonium Hamiltonian can be, by design, less sensitive to decoherence than the transmon. We present measurements of relaxation times for the entire range of flux variation and discuss energy relaxation in light of dielectric, inductive, and quasiparticle losses.

4:18PM C25.00010 A Study of the Multi-Mode Purcell Effect for a Transmon in 3D Circuit QED , ANDREI PETRENKO, LUYAN SUN, JACOB BLUMOFF, SIMON NIGG, STEVE GIRVIN, ROBERT SCHOELKOPF, Yale University Department of Applied Physics — Although superconducting 3D transmon qubits offer a promising path toward realizing an architecture for quantum computation, they are still limited by decoherence processes that are not yet fully understood. Qubit T_1 relaxation due to the Purcell Effect presents one such limitation on coherence times, but thus far a complete model of Purcell processes for transmons in 3D cavities, beyond the approximation of a single cavity mode and lumped element qubit, has been absent. Employing a simple scheme to vary the decay rate κ (or quality factor Q) of our cavities in-situ we explore in detail how multiple cavity modes contribute to qubit T_1 decay in the Purcell regime. In addition, we show the continued dependence of qubit T_1 on cavity κ as we systematically decouple from our cavity and are no longer Purcell-limited and how this dependence is related to a steady rise in qubit excited state population. Our findings are consistent with theory we have developed based on an effective circuit model for the cavity-qubit system, and set the stage for continuing the study of the multi-mode Purcell Effect by means of in-situ tuning of not just the cavity coupling, but the qubit frequency itself.

4:30PM C25.00011 Entanglement of two superconducting qubits in a three-dimensional architecture via monochromatic two-photon excitation[1] , STEFANO POLETTO, JAY M. GAMBETTA, SETH T. MERKEL, JOHN A. SMOLIN, JERRY M. CHOW, A.D. CORCOLES, D.W. ABRAHAM, CHAD RIGETTI, MATTHIAS STEFFEN, IBM T.J. Watson Research Center, Yorktown Heights, NY — The superconducting qubit approach for the realization of a quantum processor is a promising candidate because of its compatibility with silicon microfabrication techniques. The coherence times of superconducting devices have continuously improved in the previous decade, with the most noticeably enhancement recently obtained by placing the qubit inside a three-dimensional waveguide cavity. I will present a novel implementation of a two-qubit three dimensional architecture using superconducting qubits, and I will describe a new gate for the direct generation of maximally entangled Bell states. The gate employs the forbidden two-photon 00 - 11 transition, made bright by the interaction between non computational energy levels. A microwave drive tuned to this transition induces Rabi-like oscillations between the ground and doubly excited state via the Bell basis, allowing the generation of entangled states.

4:42PM C25.00012 Measurement of a three-dimensional circuit QED system with a down-converting parametric amplifier[1] , CHAD RIGETTI, DOUG MCCLURE, IBM T. J. Watson Research Center, LAFE SPIETZ, Brooklyn Quantum Works, JAY GAMBETTA, STEFANO POLETTO, ERIK LUCERO, ANTONIO CORCOLES, JERRY CHOW, JIM ROZEN, MATTHIAS STEFFEN, MARK KETCHEN, IBM T. J. Watson Research Center, KATRINA SLIWA, FLAVIUS SHACKERT, MICHAEL HATRIDGE, BALEEGH ABDO, MICHEL DEVORET, Department of Applied Physics, Yale University — We describe measurements of a superconducting transmon qubit in a waveguide cavity with a Josephson Parametric Converter (JPC) operated as a down-converter with gain. The JPC signal mode is matched to the waveguide cavity at approximately 11.2GHz while the amplified signal, taken from the idler port, is roughly an octave lower at 5.5GHz. Operating the system in this down-conversion-with-gain mode makes use of the JPC's capability to act as both a parametric amplifier and a noiseless frequency converter. Further, it decouples the qubit measurement frequency from the functional frequencies of all components following the JPC in the measurement chain. This work thus provides a framework for a turnkey near-quantum-limited measurement chain which can be standardized and optimized over a narrow band without placing constraints on the qubit/cavity system.

4:54PM C25.00013 Ultra-broadband microwave travelling-wave parametric amplifier for qubit readout , CHRIS MACKLIN, QNL, UC Berkeley, D.H. SLICHTER, NIST - Boulder, O. YAAKOBI, INRS-EMT, 1650 Boul. Lionel Boulet, Varennes, Quebec, J3X 1S2 Canada, L. FRIEDLAND, Racah Institute of Physics, The Hebrew University, Jerusalem 91904, Israel, V. BOLKHOVSKY, D.A. BRAJE, G. FITCH, W.D. OLIVER, MIT Lincoln Laboratory, Lexington, MA, USA, I. SIDIQI, QNL, UC Berkeley — Superconducting parametric amplifiers (paramps) have been used to demonstrate qubit readout approaching the quantum limit in the gigahertz regime. A common limitation of these amplifiers has been relatively small bandwidth due to the use of a resonant nonlinearity. We present measurements of a novel type of paramp based on a superconducting non-linear transmission line. Due to the absence of a resonant structure, these devices achieve useful gain with instantaneous bandwidth approaching 4 GHz. We present detailed measurements of amplifier performance metrics and scattering parameters. Additionally, we have coupled this amplifier to a 3D transmon qubit both directly and via an isolator for comparison. We discuss qubit coherence times and readout performance. This type of amplifier is a strong candidate for an ultra-low-noise following amplifier in frequency-multiplexed qubit readout schemes.

5:06PM C25.00014 High fidelity all-microwave controlled-phase gate for superconducting qubits by cavity vacuum displacement , HANHEE PAIK, Raytheon BBN Technologies and Yale University, D. ZHOU, M.D. REED, G. KIRCHMAIR, L. FRUNZIO, S.M. GIRVIN, R.J. SCHOELKOPF, Yale University — We demonstrate a new all-microwave controlled phase entangling gate for the superconducting qubits in the three-dimensional circuit QED (3D cQED) architecture. The gate exploits the strong coupling between qubits and a cavity, wherein the cavity frequency dispersively shifts depending on the qubit register state. We off-resonantly displace the cavity vacuum state; each computational state evolves a different phase due to the dispersive coupling, yielding a conditional phase. While designed to exploit the advantages of the 3D cQED architecture, the gate requires only dispersive coupling, making the gate applicable to a wide variety of superconducting qubit architectures. We demonstrate 98% gate fidelity evaluated by quantum process tomography, and will discuss how appropriate choices of system parameters could increase this number and how we could minimize the gate infidelity due to measurement induced dephasing and non-adiabatic gate procedure.

2:30PM C26.00001 Interplay of charge and spin coherence in Landau-Zener interferometry in double quantum dots[1]

, HUGO RIBEIRO, University of Konstanz — Landau-Zener-Stückelberg-Majorana (LZSM) physics has been exploited to coherently manipulate two-electron spin states in a GaAs double quantum dot (DQD) at a singlet (S)-triplet (T_+) anti-crossing. The anti-crossing results from the hyperfine interaction with the nuclear spins of the host material [1,2]. However, the fluctuations of the nuclear spin bath result in spin dephasing within $T_2^* \sim 10 - 20$ ns. As a consequence, the sweep through the anti-crossing would have to be performed on a timescale comparable to T_2^* to achieve LZSM oscillations with 100% visibility. Moreover, the S-T_+ anti-crossing is located near the $(1,1) - (2,0)$ interdot charge transition, where (n_l, n_r) denotes the number of electrons in the left and right quantum dot. As a result the singlet state involved in the dynamics is a superpostion of $(1,1)$ and $(2,0)$ singlet states. Here we show that it is possible to increase the oscillation visibility while keeping sweep times less than T_2^* using a tailored pulse with a detuning dependent level velocity. The pulse includes a slow level velocity portion that is chosen to coincide with the passage through the S-T_+ anti-crossing and two fast level velocity portions. The latter minimize the time spent in regions where spin and charge degrees of freedom are entangled, which renders the qubit susceptible to charge noise. The slow level velocity portion of the pulse results in a stronger effective coupling between the spins states, which increases the oscillations visibility [3,4]. In particular, we were able to obtain a visibility of ~ 0.5 for LZSM oscillations. This constitutes an important step towards the implementation of a Hadamard gate.

3:06PM C26.00002 Decoherence-protected nuclear spin quantum register in diamond

, VIATCHESLAV DOBROVITSKI, WAN JUNG KUO, Ames Laboratory US DOE, Iowa State University, Ames, IA, 50011, USA, RONALD HANSON, TIM H. TAMINIAU, Delft University of Technology, 2600 GA Delft, the Netherlands — We analyze the decoherence-protected operation of a quantum register based on the nuclear spins surrounding a nitrogen-vacancy (NV) center in diamond. Combination of the decoherence protection with the quantum gates is achieved by applying the decoupling pulses to the NV center's electronic spin in resonance with the motion of one of the nuclear spins [1,2]. In this way, many weakly coupled (tens of kHz) nuclei located far from the NV center can be combined in a quantum register. We study the limits, set by realistic experimental parameters, on the size of such a register and on the duration of the quantum gates needed for its operation. We also consider the ways of accelerating the quantum gate operation, and integration of the decoherence-protected gates with the decoupling of the nuclear spins themselves. We conclude that creation of such registers is feasible with current experimental capabilities. Work at the Ames Laboratory was supported by the Department of Energy - Basic Energy Sciences under Contract No. DE-AC02-07CH11358. [1] T. van der Sar et al., Nature 484, 82 (2012). [2] T. H. Taminiau et al., Phys. Rev. Lett. 109, 137602 (2012).

3:18PM C26.00003 Enhancement of Inter-qubit Coupling in Singlet-Triplet Qubits by Floating Metal Gate

, SHANNON HARVEY, MICHAEL SHULMAN, OLIVER DIAL, Harvard University, HENDRIK BLUHM, RWTH Aachen University, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — Spin qubits in semiconductors are promising systems for quantum computing, because they have long coherence times and are potentially scalable. However, their weak interaction with the environment, which gives their long coherence times, also makes inter-qubit interactions weak. Numerous proposals use electrostatic coupling between qubits for entangling operations, but these interactions require the qubits to be near one another. These proposals also suggest that adding a metallic gate between two qubits could increase coupling and allow the qubits to be spatially separated. We present results on two singlet-triplet (S-T_0) qubits connected by a floating metallic gate. Previous work on two-qubit operations, which use a capacitive coupling, showed that the inter-qubit coupling is weak and requires the qubits to be in close proximity. We find that the inter-qubit coupling is increased with the inclusion of a floating metal gate, which improves entangling operation fidelities and allows for these qubits to be spatially separated. Together, these improvements open the door to a scalable architecture for quantum information processing for all semiconductor spin qubit platforms.

3:30PM C26.00004 Probing quantum phase transitions on a spin chain with a double quantum dot[1]

, YUN-PIL SHIM, University of Wisconsin-Madison, SANGCHUL OH, University at Buffalo, State University of New York, JIANJIA FEI, University of Wisconsin-Madison, XUEDONG HU, University at Buffalo, State University of New York, MARK FRIESEN, University of Wisconsin-Madison — We propose a local, projective scheme for detecting quantum phase transitions (QPTs) in a quantum dot spin chain [1]. QPTs in qubit systems are known to produce singularities in the entanglement, which could in turn be used to probe the QPT. Current proposals to measure the entanglement are challenging however, because of their nonlocal nature. We present numerical and analytical evidence that entanglement in a double quantum dot (DQD) coupled locally to a spin chain exhibits singularities at the critical points of the spin chain, and that these singularities are reflected in the singlet probabilities of the DQD. This result suggests that a DQD can be used as an efficient probe of QPTs through projective singlet measurements. We propose a simple experiment to test this concept in a linear triple quantum dot. 3:42PM C26.00005 Coherent electron transfer between distant quantum dots in a linear array

, FLORIS BRAAKMAN, PIERRE BARTHELEMY, LIEVEN VANDERSYPEN, TU Delft, KAVLI INSTITUTE OFNANOSCIENCE TEAM — Tunnel coupled quantum dots form the basis for electronic charge and spin qubits in semiconductors. The tunnel coupling gives rise to quantum coherent phenomena such as exchange oscillations of neighboring spins. However, tunnel coupling strength between non-neighbouring sites is negligible and it is therefore desirable to develop a form of long range coupling. In a linear array of three quantum dots, we demonstrate an effective tunnel coupling between the outer dots through virtual occupation of discrete levels in the center dot. The coupling strength depends strongly on the detuning between center and outer dot levels. The observation of Landau-Zener-Stueckelberg oscillations demonstrates the coherent nature of the coupling. In principle the effective long-range tunnel coupling should also allow coherent exchange of remote spins.

3:54PM C26.00006 Dynamically Corrected Pulse Sequences for the Exchange Only Qubit

, GARRETT HICKMAN, JASON KESTNER, University of Maryland, Baltimore County — In the exchange-only qubit, hyperfine interactions of qubit electrons with neighboring atoms introduce decoherence into the basis states and mix them with a third leaked state. We theoretically derive a scheme for performing arbitrary single-qubit rotations on the exchange-only qubit while canceling all hyperfine-induced errors to first order. We compare numerically the performance of the resulting pulse sequences with that of the simplest naïve implementations for a range of hyperfine interaction strengths. While for typical operations these sequences are roughly 50 times longer than a simple uncorrected pulse, error is significantly reduced. We show that for hyperfine field inhomogeneities less than one thirtieth of the maximum exchange strength, typical hyperfine-induced errors are reduced by at least an order of magnitude.

4:06PM C26.00007 Composite pulses robust against charge noise and magnetic field noise for universal control of a singlet-triplet qubit[1] , XIN WANG, EDWIN BARNES, Condensed Matter Theory Center, University of Maryland, College Park, JASON P. KESTNER, Department of Physics, University of Maryland, Baltimore County and Condensed Matter Theory Center, University of Maryland, College Park, LEV S. BISHOP, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We generalize our SUPCODE pulse sequences [1] for singlet-triplet qubits to correct errors from imperfect control. This yields gates that are simultaneously corrected for both charge noise and magnetic field gradient fluctuations, addressing the two dominant T_2^* processes. By using this more efficient version of SUPCODE, we are able to introduce this capability while also substantially reducing the overall pulse time compared to the previous sequence. We show that our sequence remains realistic under experimental constraints such as finite bandwidth. [1] Wang et al., "Composite pulses for robust universal control of singlet-triplet qubits", Nat. Commun. 3, 997 (2012)

[1]This work is supported by LPS-NSA-CMTC, IARPA-MQCO and CNAM.

4:18PM C26.00008 Composite multi-qubit gates dynamically corrected against charge noise and magnetic field noise for singlet-triplet qubits[1] , JASON KESTNER, Department of Physics, University of Maryland, Baltimore County, and Condensed Matter Theory Center, University of Maryland, College Park, EDWIN BARNES, XIN WANG, Condensed Matter Theory Center, University of Maryland, College Park, LEV BISHOP, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We use previously described single-qubit SUPCODE pulses on both intra-qubit and inter-qubit exchange couplings, integrated with existing strategies such as BB1, to theoretically construct a CNOT gate that is robust against both charge noise and magnetic field gradient fluctuations. We show how this allows scalable, high-fidelity implementation of arbitrary multi-qubit operations using singlet-triplet spin qubits in the presence of experimentally realistic noise.

[1]This work is supported by LPS-NSA-CMTC, IARPA-MQCO and CNAM.

4:30PM C26.00009 Dynamically corrected gates for singlet-triplet spin qubits with control-dependent errors[1] , N. TOBIAS JACOBSON, WAYNE M. WITZEL, ERIK NIELSEN, MALCOLM S. CARROLL, Sandia National Laboratories — Magnetic field inhomogeneity due to random polarization of quasi-static local magnetic impurities is a major source of environmentally induced error for singlet-triplet double quantum dot (DQD) spin qubits. Moreover, for singlet-triplet qubits this error may depend on the applied controls. This effect is significant when a static magnetic field gradient is applied to enable full qubit control. Through a configuration interaction analysis, we observe that the dependence of the field inhomogeneity-induced error on the DQD bias voltage can vary systematically as a function of the controls for certain experimentally relevant operating regimes. To account for this effect, we have developed a straightforward prescription for adapting dynamically corrected gate sequences that assume control-independent errors into sequences that compensate for systematic control-dependent errors. We show that accounting for such errors may lead to a substantial increase in gate fidelities.

[1]Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:42PM C26.00010 High fidelity gates in quantum dot spin qubits[1] , MARK FRIESEN, TECK SENG KOH, S. N. COPPERSMITH, University of Wisconsin - Madison — A variety of logical qubits and quantum gates have been proposed for quantum computer architectures using top-gated quantum dots. Despite their differences, we show that many combinations of qubits and gates can be evaluated on an equal footing by optimizing the gating protocols for maximum fidelity. Here, we evaluate single-qubit gate operations for two types of logical-qubits: singlet-triplet qubits and quantum dot hybrid qubits. In both cases, transitions between the qubit states are controlled by the exchange interaction between the dots, which in turn depends on the tunnel coupling and the detuning. We compute the fidelities for three exchange gate protocols: a dc pulsed gate, an ac resonant gate, and stimulated Raman adiabatic passage (STIRAP). Remarkably, we find that the optimized fidelities for all three gates follow a simple scaling law; the maximum fidelity depends only on the range of parameters that can be achieved experimentally. We show that a singlet-triplet qubit can be pulse-gated with significantly higher fidelity than a hybrid qubit, and that the highest overall fidelity should be achieved in a hybrid qubit using a STIRAP gating protocol.

4:54PM C26.00011 Theoretical hyperfine decay functions in triple quantum dots[1] , THADDEUS LADD, HRL Laboratories, LLC — Coherent oscillations in multiple quantum dots decay due to hyperfine interactions with nuclear spins. The decay functions observed in several double-dot experiments [1] agree well with simple formulae derived using the group SU(2), which is defined by exchange and hyperfine interactions in the singlet-triplet system [2]. We show that in triple dots, this theory generalizes to SU(3), with convenient representation in the basis of states of the exchange-only qubit in a decoherence-free subsystem [3]. Using some intuition from SU(3), we derive analytic formulae for the hyperfine decay functions expected in coherent oscillations in triple dots [4].

5:06PM C26.00012 High fidelity gates for exchange-only qubits in triple-quantum-dots[1] , JIANJIA FEI, University of Wisconsin - Madison, JO-TZU HUNG, University at Buffalo, State University of New York, TECK SENG KOH, YUN-PIL SHIM, University of Wisconsin - Madison, SANGCHUL OH, University at Buffalo, State University of New York, SUSAN COPPERSMITH, University of Wisconsin - Madison, XUEDONG HU, University at Buffalo, State University of New York, MARK FRIESEN, University of Wisconsin - Madison — One of the main attractions of implementing exchange-only qubits in quantum dots is their ease of control. Gate operations are performed by changing the voltages on the top-gates, to vary the tunnel coupling and/or the detuning between the dots. One of the main challenges is that when exchange interactions are turned on, charge noise will cause dephasing. Here, we explore optimal strategies for implementing logical qubit rotations in exchange-only qubits. We take into account charge noise, and challenges due to hyperfine interactions, including leakage outside the logical qubit space, and dephasing caused by fluctuations of the local nuclear fields. Our method is based on optimizing the experimentally tunable parameters to maximize the fidelity of the gate operation. /newline /newline The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official policies, either expressly or implied, of the U.S. Government.

5:18PM C26.00013 Constructing Two-Qubit Gates for Exchange-Based Quantum Computing , DANIEL ZEUCH, Dept. of Physics, University of Konstanz, Dept. of Physics and NHMFL, Florida State University, ROBERT CIPRI, N.E. BONESTEEL, Dept. of Physics and NHMFL, Florida State University — Exchange pulses are local unitary operations obtained by turning on and off the isotropic exchange interaction between pairs of spin-1/2 particles, for example electron spins in quantum dots. We present a procedure for analytically constructing sequences of exchange pulses for carrying out leakage free two-qubit gates on logical three-spin qubits. At each stage of our construction we reduce the problem to that of finding a sequence of rotations for an effective two-level system. The resulting pulse sequences are 39 pulses long, longer than the original 19-pulse sequence of DiVincenzo et al. [1] and the more recent 18-pulse sequence of Fong and Wandzura [2], both of which were obtained numerically. Like the latter sequence, our sequences work regardless of the total spin of the six spins used to encode two qubits. After introducing our method, we prove that any leakage-free sequence of exchange pulses must act on at least five of the six spins to produce an entangling two-qubit gate.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C27 GQI: Quantum Computing, Quantum Algorithms, and Quantum Simulation 329 - Alan Aspuru-Guzik, Harvard University

2:30PM C27.00001 Quantum Computing through Quantum Networks , CHENG WU, Missouri University of Science and Technology — Entanglement of two Aharonov-Bohm (AB) rings, or two artificial atoms, is similar to the entanglement of spins from two electrons. The directions of the angular momentum of two AB rings serve as the inputs for a basic two-bit computing in the quantum network. The question is whether the read-out is to be performed under a short and weak external perturbation? We found that a stronger entanglement than the situation needed for a quantum superposition combines with a strong external terminal connections is the only solution for robust classical readouts. A "half-adder" example will be presented. There has to be an inter-relation between internal and external coupling strengths. They are so adjusted for each other so that read-outs are possible.

2:42PM C27.00002 Analytically solvable driven time-dependent two-level quantum systems[1] , EDWIN BARNES, SANKAR DAS SARMA, Condensed Matter Theory Center, University of Maryland — Analytical solutions to the time-dependent Schrodinger equation describing a driven two-level system are invaluable to many areas of physics, but they are also extremely rare. Here, we present a simple algorithm based on a type of partial reverse-engineering that generates an unlimited number of exact analytical solutions for a general time-dependent Hamiltonian. We demonstrate this method by presenting several new exact solutions that are particularly relevant to qubit control in quantum computing applications. We further show that our formalism easily generates analytical control protocols for performing sweeps across energy level anti-crossings that execute perfect Landau-Zener interferometry and rapid adiabatic passage near the quantum speed limit. [1] Phys. Rev. Lett. 109, 060401 (2012)

[1]Work supported by LPS-CMTC, CNAM and IARPA

2:54PM C27.00003 Compilted Quantum Factoring Circuits , OMAR GAMEL, DANIEL JAMES, University of Toronto — Shor's factoring algorithm is held as one of the most promising and useful applications of quantum computing. It allows one to factor large numbers in polynomial time, undermining the most common cryptographic schemes in use today, such as RSA cryptography. The well known algorithm is based on the quantum fourier transform to find the period of a function, and also makes heavy use of the modular exponentiation operation, given by,

$$U : a0 \rightarrow ax^a (mod N), \tag{1}$$

where N is the number to be factored, and x is a random positive integer coprime with N. The modular exponentiation is the bottleneck of the algorithm, the portion that uses the most time. The generic algorithm can factorize any N in time order $(\log N)^3$, assuming sufficient memory space for intermediate calculations. Reducing the memory available (as long as it still lies above a certain threshold) increases the time taken by multiplicative factors, keeping its order the same in $\log(N)$. However, for a given N, or class of N's to factorize, the generic algorithm may be suboptimal, and can be optimized to result in substantial savings in both memory needed and operation time. The different suboperations involved in modular exponentiat

3:06PM C27.00004 Quantum Algorithm for Solving an NP-Complete Problem[1] , HEFENG WANG, FULI LI, Department of Applied Physics, Xi'an Jiaotong University, Xi'an 710049, China — When a probe qubit is coupled to a quantum register that represents a physical system, the probe qubit will exhibit a dynamical response only when it is resonant with a transition in the system. Using this principle, we propose a quantum algorithm for solving a specific NP-complete problem, the 3-bit Exact Cover problem, EC3. We show that on a quantum computer, the number of qubits increases linearly with the size of the EC3 problem, while the efficiency of the algorithm is independent of the size of the problem. Our results indicate that quantum computers may be able to outperform classical computers in solving NP-complete problems.

3:18PM C27.00005 Quantum Steering as a Quantum Game[1] , SAI VINJANAMPATHY, JING-LING CHEN, MILE GU, National University of Singapore, L.C. KWEK, National University of Singapore and National Institute of Education and Institute of Advanced Studies, Nanyang Technological University, 1 Nanyang Wa — "Steerable states" are a subset of entangled states, that contain in them the set of Bell non-local states. A bipartite state shared by Alice and Bob is called steerable if by performing measurements, the ensemble that Alice can produce on Bob's side is unexplained by any local hidden variable theory. We will provide an operational interpretation of quantum steering by proposing a quantum game. The probability that the players win this game will be related to quantum steering. Furthermore, we will show how the various hierarchies between entanglement, steering and Bell non-locality are preserved by this quantum game.

[1]National Basic Research Program (973 Program) of China under Grant No. 2012CB921900, NSF of China (Grant Nos. 10975075 and 11175089) and by National Research Foundation and Ministry of Education of Singapore

3:30PM C27.00006 Quantum Data Fitting , NATHAN WIEBE, University of Waterloo — We provide a new quantum algorithm that efficiently determines the quality of a least-squares fit over an exponentially large data set by building upon an algorithm for solving systems of linear equations efficiently (Harrow et al., Phys. Rev. Lett. 103, 150502 (2009)). In many cases, our algorithm can also efficiently find a concise function that approximates the data to be fitted and bound the approximation error. In cases where the input data is a pure quantum state, the algorithm can be used to provide an efficient parametric estimation of the quantum state and therefore can be applied as an alternative to full quantum state tomography given a fault tolerant quantum computer.

3:42PM C27.00007 Virtual Parallel Computing and a Search Algorithm Using Matrix Product States[1]

, EDUARDO MUCCIOLO, University of Central Florida, CLAUDIO CHAMON, Boston University — We propose a form of parallel computing on classical computers that is based on matrix product states. The virtual parallelization is accomplished by representing bits with matrices and by evolving these matrices from an initial product state that encodes multiple inputs. Matrix evolution follows from the sequential application of gates, as in a logical circuit. The action by classical probabilistic one-bit and deterministic two-bit gates such as NAND are implemented in terms of matrix operations and, as opposed to quantum computing, it is possible to copy bits. We present a way to explore this method of computation to solve search problems and count the number of solutions. We argue that if the classical computational cost of testing solutions (witnesses) requires less than $O(n^2)$ local two-bit gates acting on n bits, the search problem can be fully solved in subexponential time. Therefore, for this restricted type of search problem, the virtual parallelization scheme is faster than Grover's quantum algorithm.

3:54PM C27.00008 Google in a Quantum Network

, GIUSEPPE DAVIDE PAPARO, Universidad Complutense — In [1] we introduce the characterization of a class of quantum PageRank algorithms in a scenario in which some kind of quantum network is realizable out of the current classical internet web, but no quantum computer is yet available. This class of algorithms represents a quantization of the PageRank protocol currently employed to list web pages according to their importance. The PageRank algorithm's ranking ability has been instrumental to give structure to the web. This class of algorithms may be able to rank nodes in a quantum network. Furthermore, in this class, we have found an instance of this class of quantum protocols that outperforms its classical counterpart and may break the classical hierarchy of web pages depending on the topology of the web.

4:06PM C27.00009 Discrete-time quantum walk with history dependence

, ZLATKO DIMCOVIC, YEVGENIY KOVCHEGOV, Oregon State University — We study a discrete time quantum walk (DTQW) with explicit correlation (or, memory/history dependence) over previous steps, implemented by a unique evolution operator. Monitoring the paths affects their interferences and we expect appearance of anomalies and classical features, while the process stays unitary. For 2-step-memory we obtain a closed-form generating function, with amplitude asymptotic. The trademark ballistic peaks of DTQW remain but a sharp central peak over a few sites appears. For deeper correlations we have so far obtained a full numerical solution for up to 20 memory-steps, evolved over $10,000$'s of time-steps. As memory increases, the amplitude first develops noisy peaks in the middle, and by around 10 step-deep memory the dominant central peak settles, while the runaway peaks typical of DTQW are all but gone. This central distribution is unlike the Gaussian curve of classical walks, the spreading is still ballistic (albeit slow), the shape stabilizes, and we observe universality. These (and some other) properties appear stable. This behavior starkly differs from previous known results. We use a multidimensional coin, but the precise operator form, explicitly encoding memory dependence in the evolution, comes from our (coinless) interchange framework.

4:18PM C27.00010 Renormalization Group for Quantum Walks[1]

, STEFAN FALKNER, STEFAN BOETTCHER[2], Department of Physics, Emory University, Atlanta, GA 30322; USA, RENATO PORTUGAL[3], Laboratorio Nacional de Computacao Cienfica, Petropolis, RJ 25651-075; Brazil — A renormalization group (RG) treatment of quantum walks holds significant promise for insights into quantum transport phenomena and search algorithms for quantum computing. The generality of this approach has a good chance to elucidate salient characteristics of quantum walks on higher-dimensional lattices which at this point are unobtainable with other methods and are even difficult to study numerically. Key questions concern the scaling properties of (unitary) quantum evolution depending on the lattice type. Is there a single exponent describing the mean-square displacement of quantum walks, similar to the scenario observed in ordinary random walks, or is there a spectrum of modes, each with their own exponent? Does quantum interference ensure that these exponents are always smaller than for the respective classical random walks? To what extend do translational invariance and other lattice properties matter? Generally, what is the nature of universality in quantum walks? Our preliminary results on effectively one-dimensional lattices demonstrates how RG can be used to study quantum random walks and their asymptotic behavior.

4:30PM C27.00011 Using the graph isomorphism problem to probe differences between discrete- and continuous-time quantum random walks[1]

, KENNETH RUDINGER, JOHN KING GAMBLE, University of Wisconsin-Madison Department of Physics, ERIC BACH, University of Wisconsin-Madison Department of Computer Sciences, MARK FRIESEN, ROBERT JOYNT, S. N. COPPERSMITH, University of Wisconsin-Madison Department of Physics — Though continuous-time and discrete-time quantum walks appear superficially similar, recent studies have demonstrated potential differences in terms of algorithmic power. We investigate these disparities in the context of the graph isomorphism problem. It has been previously demonstrated that discrete-time walks of two non-interacting particles can distinguish certain difficult-to-distinguish graphs, while it has been proven that continuous-time walks of two non-interacting particles can never distinguish these graphs. We show the origins of this difference in distinguishing power, and find that, even for identical walks, subtle differences in the certificate construction algorithm can non-trivially impact the walk's distinguishing power.

4:42PM C27.00012 Experimental 1D quantum simulation using an oxide nanoelectronics platform[1]

, MEGAN KIRKENDALL, DONGYUE YANG, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh, SANGWOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison — We are interested in developing a solid state quantum simulation platform which could be used to study important Hamiltonians like the Hubbard model and investigate phenomena such as high temperature superconductivity. Using the nanoscale control that has been demonstrated in modifying the 2DEG at the $LaAlO_3/SrTiO_3$ interface[2], we are attempting to create an artificial system with which to study these phenomena that is decoupled from the underlying lattice. We use conductive AFM lithography to create one-dimensional structures at the $LaAlO_3/SrTiO_3$ interface with the goal of determining the relationship between external parameters that can be controlled in the $LaAlO_3/SrTiO_3$ system (i.e., $V(x, y)$, back gates, and side gates) and parameters in a Hubbard model description of the physical system. These tools could be used to create a solid state quantum simulation platform providing Hamiltonian level control over artificially created systems.

4:54PM C27.00013 ABSTRACT WITHDRAWN –

5:06PM C27.00014 Experimental Boson Sampling , ANDREW WHITE, MATTHEW BROOME, ALESSANDRO FEDRIZZI, SALEH RAHIMI-KESHARI, TIMOTHY RALPH, University of Queensland, JUSTIN DOVE, SCOTT AARONSON, Massachusetts Institute of Technology — Quantum computers are unnecessary for exponentially-efficient computation or simulation if the Extended Church-Turing thesis—a foundational tenet of computer science—is correct. The thesis would be directly contradicted by a physical device that efficiently performs a task believed to be intractable for classical computers. Such a task is BosonSampling: obtaining a distribution of n bosons scattered by some linear-optical unitary process. Here we test the central premise of BosonSampling, experimentally verifying that the amplitudes of 3-photon scattering processes are given by the permanents of submatrices generated from a unitary describing a 6-mode integrated optical circuit. We find the protocol to be robust, working even with the unavoidable effects of photon loss, non-ideal sources, and imperfect detection. Strong evidence against the Extended-Church-Turing thesis will come from scaling to large numbers of photons, which is a much simpler task than building a universal quantum computer.

5:18PM C27.00015 Opening up the Quantum Three-Box Problem with Undetectable Measurements , RICHARD GEORGE, University College London, LUCIO ROBLEDO, TU Delft, OWEN MARONEY, University of Oxford, MACHIEL BLOK, HANNES BERNIEN, TU Delft, DANIEL TWITCHEN, MATTHEW MARKHAM, E6, JOHN MORTON, University College London, ANDREW BRIGGS, University of Oxford, RONALD HANSON, TU Delft — One of the most striking features of quantum mechanics is the profound effect exerted by measurements alone. Sophisticated quantum control is now available in several experimental systems, exposing discrepancies between quantum and classical mechanics whenever measurement induces disturbance of the interrogated system. In practice, such discrepancies may frequently be explained as the back-action required by quantum mechanics adding quantum noise to a classical signal. Here we implement the 'three-box' quantum game (Aharonov, et al. 1991) by utilising state-of-the-art control and measurement of the nitrogen vacancy centre in diamond. In this protocol, the back-action of quantum measurements add no detectable disturbance to the classical description of the game. Quantum and classical mechanics then make contradictory predictions for the same experimental procedure, however classical observers are unable to invoke measurement-induced disturbance to explain the discrepancy. We quantify the disturbance of our measurements and obtain data ruling out any classical model by 7.8 sigma, excluding state-definiteness from our system. Our experiment is then equivalent to a Kochen-Spekker test of quantum non-contextuality that successfully addresses the measurement detectability loophole.

Session C28 GSNP: Equilibrium Statistical Mechanics, Followed by GSNP Student Speaker Award 336 - Robin Selinger, Kent State University

2:30PM C28.00001 Approximate Solutions in Planted 3-SAT , BENJAMIN HSU, Princeton University, CHRISTOPHER LAUMANN, Harvard University, RODERICH MOESSNER, Max Planck Institute for Complex Systems, SHIVAJI SONDHI, Princeton University — In many computational settings, there exists many instances where finding a solution requires a computing time that grows exponentially in the number of variables. Concrete examples occur in combinatorial optimization problems and cryptography in computer science or glassy systems in physics. However, while exact solutions are often known to require exponential time, a related and important question is the running time required to find approximate solutions. Treating this problem as a problem in statistical physics at finite temperature, we examine the computational running time in finding approximate solutions in 3-satisfiability for randomly generated 3-SAT instances which are guaranteed to have a solution . Analytic predictions are corroborated by numerical evidence using stochastic local search algorithms. A first order transition is found in the running time of these algorithms.

2:42PM C28.00002 Wang-Landau or Statistical Mechanics , GREGORY BROWN, Oak Ridge National Laboratory / Florida State Univ, DONALD M. NICHOLSON, MARKUS EISENBACH, KH. ODBADRAKH, Oak Ridge National Laboratory — The Wang-Landau algorithm and its variations provide a method for estimating a self-consistent density of states – or equivalently the entropy – of a system with many degrees of freedom. Possible benefits from generating a self-consistent estimate of the entropy and its derivative are presented for models with both discrete and continuous values of the energy. In addition, the advantage of computing thermodynamic quantities as derivatives of the estimated entropy over summation over the density of states is shown.

2:54PM C28.00003 Coarse-graining renormalization by higher-order singular value decomposition , ZHIYUAN XIE, JING CHEN, MINGPU QIN, Institute of Physics, Chinese Academy of Sciences, JINWEI ZHU, Institute of Computational Mathematics and Scientific/Engineering Computing, Academy of Mathematics and Systems Science, Chinese Academy of Sciences, LIPING YANG, Beijing Computational Science Research Center, Beijing, TAO XIANG, Institute of Physics, Chinese Academy of Sciences, and Institute of Theoretical Physics, Chinese Academy of Sciences — We propose a novel coarse graining tensor renormalization group method based on the higher-order singular value decomposition. This method provides an accurate but low computational cost technique for studying both classical and quantum lattice models in two- or three-dimensions. We have demonstrated this method using the Ising model on the square and cubic lattices. By keeping up to 16 bond basis states, we obtain by far the most accurate numerical renormalization group results for the 3D Ising model. We have also applied the method to study the ground state as well as finite temperature properties for the two-dimensional quantum transverse Ising model and obtain the results which are consistent with published data.

3:06PM C28.00004 Cluster scaling in the dilute Ising model[1] , KANG LIU, JAMES SILVA, WILLIAM KLEIN, Boston University, HARVEY GOULD, Clark University — We consider the cluster mapping method to map the critical point in a site-diluted Ising model onto a correlated site-bond percolation. First, we prove the Coniglio-Klein bond probability has the same form in the dilute Ising model with a proper chosen temperature. Then we study the cluster size distribution near the critical point in 2D dilute Ising model with long range interactions. The power law distribution of the clusters size at the critical point has the same exponent as the mean field Ising critical point, which is consistent with the Harris criterion for the long range Ising model. In addition, we apply this percolation mapping method to identify the nucleating droplet near the spinodal and it shows that the largest cluster size could be used to find the time when nucleating droplet occurs.

[1]The authors wish to thank for the DOE's support.

3:18PM C28.00005 Properties of the Ising Model Density of States , ROBERT HOSKEN, The Aerospace Corporation — The Ising model Density of States (DOS) is a histogram of all the Ising model microstates binned into macrostates with the same values of the energy variables, magnetism and interaction energy. When the DOS three-dimensional surface is known analytically it can be multiplied by the Boltzmann function and summed over all possible values of the energy variables to obtain the statistical mechanics partition function, Z, where Z is a function of the temperature, the single bond energy strength, and the external magnetic field. This summation becomes an integration in the thermodynamic limit, and the result is exact in the high temperature regime. Analytical expressions for the descriptive statistics of the energy variables are presented for nearest neighbor spin interactions in a linear chain, a square lattice, and a simple cubic lattice, all for the case of periodic boundary conditions. The properties considered are the moments of the variables to the fourth order: mean, variance, correlation, skewness, and kurtosis. The DOS surface has a single peak with a known location and height, and the base of the surface lies within an isosceles triangle. Examination of this triangle shows the feasible ferromagnetic and antiferromagnetic regions, and the location of the ground states.

3:30PM C28.00006 Link duality: an extension of Kramers-Wannier duality , JOE MITCHELL, VICTOR GALITSKI, University of Maryland — Lattice duality, in the manner the famous Kramers-Wannier duality of 1941, has been thoroughly investigated. However, even now there are very simple unexplored extensions to be uncovered and utilized. We present one such by including site energies in the model Hamiltonian and examining the dual model that results. This grants a dual model with dual variables where the original model had interactions and vice versa. We can apply this extension to the Ising model and the XY model, among others, and it is doubtful that it would not be as applicable to many classical models with traditional dualities. The dual models tend to be less dependent on the lattice and interaction of the original models. Finally, we discuss the possible applicability of these extended dualities to a Kramers-Wannier like duality for fermions.

3:42PM C28.00007 Magnetization plateaus in an antiferromagnetic Ising chain with single-ion anisotropy and quenched disorder[1] , NILTON BRANCO, Universidade Federal de Santa Catarina, Departamento de Fisica, MINOS NETO, JOSE RICARDO DE SOUSA, Universidade Federal do Amazonas, Departamento de Fisica, PEDRO PICCINI, Universidade Federal de Santa Catarina, Departamento de Fisica — We have studied the presence of plateaus on the low-temperature magnetization of an antiferromagnetic spin-1 chain, as an external uniform magnetic field is varied. A crystal-field interaction is present in the model and the exchange constants follow a random quenched (binomial or Gaussian) distribution. Using a transfer-matrix technique we calculate the largest Lyapunov exponent and, from it, the magnetization at low temperatures as a function of the magnetic field, for different values of the crystal-field and of the width of the distributions. For the binomial distribution, the number of plateaus increases, with respect to the uniform case (F. Litaiff, J. R. de Sousa, and N. S. Branco, Sol. St. Comm. **147**, 494 (2008)) and their presence can be linked to different ground states, when the magnetic field is varied. For the Gaussian distributions, the uniform scenario is maintained, for small widths, but the plateaus structure disappears, as the width increases. We present also preliminary results for the behavior of the plateaus when aperiodic modulations are introduced.

3:54PM C28.00008 A generalization of equipartion and virial theorems: maximum entropy derivation[1] , GONZALO GUTIERREZ, SERGIO DAVIS, Departamento de Fisica, Facultad de Ciencias, Universidad de Chile — It is shown that, for a continuous maximum-entropy distribution obtained from an arbitrary number of simultaneous constraints, an estimator for a given conjugate variable can be constructed. Thus, we have derived a general theorem connecting the values of Lagrange multipliers in Maximunm Entropy (MaxEnt) inference to expectation values related to an arbitrary trial function. These estimators provide another tool to widen the applicability of Jaynes' formalism (E. T. Jaynes, Phys. Rev. 106, 620 (1957)), as well as insight into the interpretation of the hypervirial relations known in Statistical Mechanics for the canonical ensemble and Rugh's dynamical temperature for the microcanonical ensemble (H. H. Rugh, Phys. Rev. Lett. 78, 772 (1997); G. Rickayzen and J. G. Powles, J. Chem. Phys. 114, 4333 (2001)). Some examples to show the applicability of these new relations within and beyond standard Statistical Mechanics will be presented.

[1]Support from Fondecyt-Chile 1120603 (GG) and 3110017 (SD) is gratefully acknowledged.

4:06PM C28.00009 Random perfect lattices and the sphere packing problem , ALEXEI ANDREANOV, Max Planck Institute for Physics of Complex Systems, Noethnitzer Str. 38, 01187 Dresden, Germany, ANTONELLO SCARDICCHIO, The Abdus Salam ICTP, 11 Strada Costiera, 34151 Trieste, Italy — We study random sets of perfect lattices in dimensions up to $d = 19$. Perfect lattices are relevant for solution of lattice sphere packing problem. In fact the best lattice packing is a perfect lattice and perfect and eutactic lattices are local maxima of the packing fraction. We use a stochastic generating algorithm for perfect lattices and define a random ensemble with an effective temperature (reminiscent of a Monte Carlo simulation) to study typical properties of perfect lattices and show how as the temperature is decreased the best known packers are easily recovered. We find that the typical perfect lattices are denser than known families and propose two hypotheses for typical packing density between which we cannot distinguish: $\phi \sim 2^{-(0.84\pm0.06)d}$ (improvement of the Minkowksi bound), and a competitor $\phi \sim d^{-ad}$ with a very small coefficient $a = 0.06 \pm 0.04$. We also find properties of the random walk which are suggestive of a glassy system already for moderately small dimensions.

4:18PM C28.00010 Statistical Mechanics and Shape Transitions in Microscopic Plates , EE HOU YONG, L. MAHADEVAN, Harvard University — We investigate the statistical mechanics of elliptical plates of parabolic thickness with free boundary condition using both analytical techniques and Monte Carlo simulation. We consider the energy landscape of this system and show that plates with spontaneous Gaussian curvature exhibit two minima while plates with zero Gaussian curvature only exhibit one stable conformation. For plate that exhibits bistability, it can undergo shape transitions between the two conformation minima if the white noise is large enough. Plates with negative spontaneous Gaussian curvature are found to be more susceptible to shape changes than its positive counterparts. Our results are applicable to many disk-like objects in the microscopic world where fluctuation effects are important.

4:30PM C28.00011 ABSTRACT WITHDRAWN –

4:42PM C28.00012 Forecasting large earthquakes using small-quake correlations , BRADEN BRINKMAN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, YEHUDA BEN-ZION, University of Southern California, J.T. UHL, Retired, KARIN DAHMEN, University of Illinois at Urbana-Champaign — It has long been speculated that periodic stress variations, such as the tides, may trigger earthquakes, and hence tide-earthquake correlations could be used as signals for predicting large earthquakes prior to failure. We developed a simple probabilistic model of earthquake triggering which we used to simulate series of earthquake events in a fault subjected to external periodic stresses of amplitudes and frequencies representative of tidal or seasonal stress variations. By analyzing correlations between small events and periodic stress cycles, we compute the probability that a large event will occur. We find that seasonal stresses are better predictors of impending large earthquakes. In addition, our results also apply to many other sheared frictional stick-slip systems which display small slips, such as rock interfaces or granular matter.

4:54PM C28.00013 Graphicality of random scale-free networks with general degree cutoffs , YONGJOO BAEK, DANIEL KIM, Department of Physics, KAIST, MEESOON HA, Department of Physics Education, Chosun University, HAWOONG JEONG, Department of Physics, KAIST — We study graphicality of random scale-free networks with arbitrary degree cutoffs in the thermodynamic limit, which refers to realizability of degree sequences randomly generated with the degree exponent γ and the upper degree cutoff k_c as the number of nodes N goes to infinity. While a recent study[1] found that only degree sequences with $\gamma > 2$ or $\gamma < 0$ are graphical if $k_c = N - 1$ using the graphicality criterion proved by Erdös and Gallai,[2] we generalize the study to different upper cutoffs. To ensure graphicality of degree sequences, it is found that the upper cutoff must be lower than $k_c \sim N^{1/\gamma}$ for $\gamma < 2$, whereas any upper cutoff is allowed for $\gamma > 2$. This is also numerically verified, using both random and deterministic sampling of degree sequences. Our result can be interpreted as giving a fundamental constraint on the structure of random scale-free networks.

5:06PM C28.00014 Slower recovery in space before collapse of connected populations , LEI DAI, KIRILL KOROLEV, JEFF GORE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Slower recovery from perturbations near a tipping point and its indirect signatures in fluctuation patterns have been suggested to alert catastrophes in a wide variety of systems. Recent studies of populations in the field and in the laboratory have used time-series data to confirm some of the theoretically predicted early warning indicators, such as an increase in recovery time or in the size and timescale of fluctuations. However, the performance of warning signals in spatially extended systems remains to be examined empirically. Here we use spatially extended yeast populations, an experimental system displaying a fold bifurcation, to evaluate early warning signals based on spatio-temporal fluctuations and to identify a novel warning indicator in space. We found that two leading indicators based on fluctuations increased before collapse of connected populations; however, the magnitude of increase was smaller than that observed in isolated populations, possibly because local variation is reduced by dispersal. Furthermore, we propose a generic indicator based on deterministic spatial patterns, "recovery length." As the spatial counterpart of recovery time, recovery length is defined as the distance for connected populations to recover from perturbations in space (e.g. a region of poor quality). In our experiments, recovery length increased substantially before population collapse, suggesting that the spatial scale of recovery can provide a superior warning signal before tipping points in spatially extended systems.

5:18PM C28.00015 An exactly solvable model of Maxwell's demon , DIBYENDU MANDAL, Department of Physics, University of Maryland, College Park, CHRISTOPHER JARZYNSKI, Department of Chemistry and Biochemistry, and Institute for Physical Science and Technology, University of Maryland, College Park — The paradox of Maxwell's demon has stimulated numerous thought experiments, leading to discussions about the thermodynamic implications of information processing. However, the field has lacked a tangible example or model of an autonomous, mechanical system that reproduces the actions of the demon. To address this issue, we introduce an explicit model of a device that can deliver work to lift a mass against gravity by rectifying thermal fluctuations, while writing information to a memory register. We solve for the steady-state behavior of the model and construct its nonequilibrium phase diagram. In addition to the engine-like action described above, we identify a "Landauer eraser" region in the phase diagram where the model uses externally supplied work to remove information from the memory register. Our model offers a simple paradigm for investigating the thermodynamics of information processing by exposing a transparent mechanism of operation.

Session C29 DPOLY: Flow in Confinement and Porous Media 337 - Howard Stone, Princeton University

2:30PM C29.00001 Colloidal jamming in nano-confinements observed with SESANS[1] , RANA ASHKAR, University of Maryland at College Park/ NIST Center of Neutron Research, ROGER PYNN, Indiana University Bloomington/ Oak Ridge National Laboratory — The behavior of matter in nano-confinements is being investigated as a means for obtaining controlled highly-ordered nanomaterials. To understand this behavior a 3D structural characterization of the confined matter is necessary. Non-destructive probing of such samples challenges conventional microscopy techniques. On the other hand, the submicron size of a single confinement is impractical for neutron and x-ray scattering experiments but this dilemma can be overcome by using a confining matrix made up of an array of identical confinements, $e.g.$ the grooves of a diffraction grating. The caveat is that the periodicity of the sample amplifies dynamical scattering effects that are not accounted for in approximate scattering theories and a full dynamical theory (DT) calculation becomes unavoidable. Dynamical theory calculations, applied to neutron spin-echo small angle scattering (SESANS) measurements on nanostructured gratings, give good account of all the data sets we collected so far in reflection and transmission scattering geometries. Calculations on recent measurements performed on a silica suspension in contact with the grooves of a diffraction grating show colloidal jamming in the grooves.

2:42PM C29.00002 Numerical Studies into Flow Profiles in Confined Lubricant , LUCA DI MARE, ALEKS PONJAVIC, JANET WONG, Imperial College London — This paper documents a computational study of flow profiles in confined fluids. The study is motivated by experimental evidence for deviation from Couette flow found by one of the authors (JSW). The computational study examines several possible stress-strain relations. Since a linear profile is the only possible solution for a constant stress layer even in presence of a power law, the study introduces a functional dependence of the fluid viscosity on the distance from the wall. Based on this dependence, a family of scaling laws for the velocity profile near the wall is derived which matches the measured profiles. The existence of this scaling law requires the viscosity of the fluid to increase at least linearly away from the wall. This behaviour is explained at a microscopic level by considerations on the mobility of long molecules near a wall. This behaviour is reminiscent of the variation of eddy length scales in near-wall turbulence.

2:54PM C29.00003 Through-Thickness Flow Profile Determination of Confined Lubricant[1] , JANET WONG, ALEKS PONJAVIC, Imperial College London — The knowledge of the through-thickness flow profile of lubricants confined between two rubbing surfaces is necessary for the friction prediction of lubricated engineering systems. While it is crucial to materials selection and engineering design, little work on the direct measurement of lubricant flow has been performed in elastohydrodynamic lubrication (EHL) regime as the nanoscopic film thickness bars the use of conventional techniques. Photobleached-fluorescence imaging was applied to obtain the first experimental flow profile of a $\sim$100 nm lubricant film within an EHL contact. Mapping of flow profiles was also carried out across the contact. The investigated lubricants show multiple flow phenomena. They do not follow the predicted Couette flow, often assumed in tribology theory. Two distinct flow conditions were observed: transition from Couette flow to a non-linear velocity profile; and shear banding, or dilation. Both conditions were shown to depend on position and normal stress experienced by the lubricant. Causes, such as pressure gradient and limiting shear stress, and the effect on traction, will be discussed.

3:06PM C29.00004 The Electrophoretic Mobility of a Polyelectrolyte within a Radially Confining Potential Well , TYLER SHENDRUK, MARTIN BERTRAND, GARY W. SLATER, University of Ottawa — We demonstrate that a polyelectrolyte electrophoresing while radially confined by a mechanical force has a conformationally dependent electrophoretic mobility that differs from its free-draining value. The mobility increases as a function of the confining harmonic potential and in the absence of solid walls. Mesoscale MPCD-MD hybrid simulations that include electro-hydrodynamics through a mean-field Debye Hückel approximation will be presented for a variety of well widths and contour lengths, demonstrating that mobility increases with confinement after a critical point but remains independent of polymerization. For this reason, models based on a change of monomer friction coefficient at the confinement boundary (such as those recently put forward to explain experimentally measured mobility polyelectrolytes confined within nano- and microfluidic channels) are not sufficient to explain our observations. Since the potential acts perpendicular to the electric field and only on the monomers, the Electro-Hydrodynamic Equivalence Principle does not predict the mobility to differ. We present a course-grained theory explaining these findings in terms of hydrodynamic coupling within overlapping diffuse layers.

3:18PM C29.00005 Specific Heat Capacity of Physically Confined Ethylene glycol in Nano Pores[1] , SAMUEL AMANUEL, WILL LINTHICUM, Union College, Dept. of Phys. & Astro. — Sensible heat is a cheap and effective means of storing solar energy where energy storage density can be improved by enhancing the specific heat capacity of the heat transfer materials. Formulating composite materials of heat transfer fluids is a mechanism by which the bulk specific heat capacity can be altered and preferably increased. Traditionally, the specific heat capacity of composite material is evaluated from the weighed average of the individual specific heat capacities of the constituents. This, however, does not take into account the effect of interfacial atoms and molecules. The effect of interfacial atoms and molecules becomes increasingly significant when one of the constituents has dimensions in nano meters. In this study, we evaluate the role of interfacial molecules on the specific heat capacity of composite systems. In order to systematically control the interfacial molecules, we have measured the specific heat capacity of ethylene glycol when it is physically confined in nano pores.

3:30PM C29.00006 Diffusion in a soft confining environment: Dynamic effects of thermal fluctuations , BENOIT PALMIERI, SAMUEL SAFRAN, Weizmann Institute of Science — A dynamical model of a soft, thermally fluctuating two-dimensional tube is used to study the effect of thermal fluctuations of a confining environment on diffusive transport. The tube fluctuations in both space and time are driven by Brownian motion and suppressed by surface tension and the rigidity of the surrounding environment. The dynamical fluctuations modify the concentration profile boundary condition at the tube surface. They decrease the diffusive transport rate through the tube for two important cases: uniform tube fluctuations (wave vector, $q = 0$ mode) for finite tube lengths and fluctuations of any wave vector for infinitely long tubes.

3:42PM C29.00007 Probing The Dynamics Of Flow Within A 3D Porous Medium, From The Pore Scale Up , SUJIT DATTA, HARRY CHIANG, Department of Physics, Harvard University, T.S. RAMAKRISHNAN, Schlumberger-Doll Research, Cambridge MA, DAVID WEITZ, Department of Physics, Harvard University — Flows through micro and nano scale pores are ubiquitous; they arise in everyday situations, such as in forcing fluid out of a wet sponge, to important technological applications, including oil recovery, groundwater remediation, geological CO_2 storage, and even nutrient transport through mammalian tissues. Such flows are typically modeled using a simple continuum approach, which neglects local, pore scale variations in the flow. Here, we present an experimental technique to directly visualize flow within a 3D porous medium over a broad range of length scales, from the scale of individual pores to that of the entire medium. We quantify the dynamics of the flow, both without and with residual trapping of an additional, immiscible fluid within the medium. The pore space is highly complex and interconnected; nevertheless, we find excellent agreement between our measurements and a dramatically simplified mean-field picture of flow.

3:54PM C29.00008 Forced drainage and imbibition in microfluidic porous media , HOKCHHAY TANN, EMILIE DRESSAIRE, Trinity College, JINKEE LEE, Sungkyunkwan University , HOWARD STONE, Princeton University — We present an experimental study on the dynamics of two-phase flow in microfabricated porous media. In particular we focus on pressure-driven imbibition and drainage in two-dimensional networks of microchannels. We vary the geometrical features of the network, viscosity of the non-wetting fluid and surface chemistry of the microchannels. The rate of displacement and entrapment of the liquid are studied. A simple model that accounts for capillary and viscous effects is compared with the experimental results.

4:06PM C29.00009 Unusual Properties of Water Confined in Nanoporous Silica Glasses , CAMILLA KIRKEMO, University of Oslo, Physics of Geological Processes, ADARSH SHEKHAR, University of Southern California, Collaboratory for Advanced Computing and Simulations, ANDERS MALTHE-SORENSSEN, University of Oslo, Physics of Geological Processes, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California, Collaboratory for Advanced Computing and Simulations — The structure and dynamics of water confined in nanoporous silica are different from that of bulk water, and insight into the properties of confined water is important for our understanding of many geological and biological processes. We use reactive molecular dynamics simulations to study the structure and dynamics of nanoconfined water between 100 and 300K. The simulations are based on experimentally validated force fields for silica and water. These force fields allow dissociation of water molecules. We prepare nanoporous silica systems with pore sizes in the range 1-6 nm, and study the behavior of water in the nanopores. We observe a mixture of high-density and low-density water in the pores, and hysteresis in the energetics of water upon cooling and heating. We will present results for the structure and diffusion of water near surfaces and in the interior regions of nanopores as a function of temperature.

4:18PM C29.00010 Analysis of gas transport in polymer electrolyte fuel cells using porous structure constructed from X-ray nano CT[1] , IKUYA KINEFUCHI, The University of Tokyo, JUNPEI OYAMA, KOJI YOKOYAMA, NORIO KUBO, FC-Cubic, TAKASHI TOKUMASU, Tohoku University, YOICHIRO MATSUMOTO, The University of Tokyo — This paper describes the analysis of gas transport in micro porous layers of polymer electrolyte fuel cells based on the three-dimensional structure obtained from X-ray nano computed tomography (CT). The polygonal surface representation of the porous structure was constructed from the cross-sectional CT images using the marching tetrahedrons algorithm. The diffusion flux through the porous layer was evaluated by the direct simulation Monte Carlo method since the characteristic pore size is comparable to the mean free path of gas molecules. The numerical simulation well reproduces the experimentally observed pressure dependence of diffusion resistance originating from the transition between Knudsen and molecular diffusion regimes. The effect of porous media morphology on gas transport was examined by an analysis of the trajectories of transmitted molecules through the porous layer.

4:30PM C29.00011 Microfluidics of ordered fluids , ANUPAM SENGUPTA, Max Planck Institute for Dynamics and Self Organization — Flow of ordered fluids (e.g. liquid crystals) is inherently complex due to the coupling between the flow and the long-range orientational order. Experiments carried out with nematic liquid crystals at micro scales further reveal the influence of surface properties on the static and dynamic outcomes. Microfluidics provide a convenient platform to tune one or more of the above competing components, and explore the resulting equilibrium states. The delicate but intricate balance between the viscous, elastic and surface forces was consequently used to devise optofluidic and micro-scale-transport applications. On one hand the novel applications complement the conventional microfluidic capabilities, and on the other hand, broaden the reach of *isotropic* microfluidics by offering competitive advantages. Standard microfluidic techniques and a combination of polarizing optical microscopy, fluorescence confocal polarizing microscopy and particle tracking methods were employed for the investigations.

4:42PM C29.00012 The Casimir effect in microfluidics , ALEJANDRO RODRIGUEZ-WONG, ALEXANDER WOOLF, LULU LIU, DAVID WOOLF, Harvard School of Engineering and Applied Sciences, STEVEN JOHNSON, MIT Department of Mathematics, FEDERICO CAPASSO, Harvard School of Engineering and Applied Sciences, HARVARD SEAS COLLABORATION, MIT DEPARTMENT OF MATHEMATICS COLLABORATION — We describe predictions of unusual Casimir and light-induced interactions between bodies immersed in fluids, including tunable and highly temperature-dependent stable suspensions of compact microspheres. We exploit recently developed, sophisticated computational techniques for modeling Casimir interactions in arbitrary geometries to study fluid deformations in corrugated surfaces with features on the scale of the fluid-layer thickness, and quantify the contributions of non-additive electromagnetic effects in those geometries. Unlike previous calculations of wetting and dewetting effects based on the Lifshitz formula, our approach is fully general and allows studies of complex microfluidic environments with no uncontrolled approximations. Time permitting, we present preliminary experimental results.

4:54PM C29.00013 Molecular dynamics simulation for vapor-liquid coexistence of water in nanocylinder , TOSHIKI MIMA, IKUYA KINEFUCHI, YUTA YOSHIMOTO, NOBUYA MIYOSHI, Department of mechanical engineering, University of Tokyo, Bunkyo-ku, Japan, AKINORI FUKUSHIMA, TAKASHI TOKUMASU, Institute of fluid science, Tohoku University, Sendai-shi, Miyagi, Japan, SHU TAKAGI, YOICHIRO MATSUMOTO, Department of mechanical engineering, University of Tokyo, Bunkyo-ku, Japan — Molecular dynamics simulation was conducted in order to investigate the vapor-liquid coexistence of the water molecules in nanopore. In this research, the Lennard-Jones energy parameter between a water molecule and an atom of nanopore was optimized so as to model the contact angle between a water droplet and the carbon material in the fuel cell. The TIP4P/2005 as the model of a water molecule was used; this model produces well the vapor-liquid coexistence line. All of the systems were equilibrated by Nosé-Hoover thermostat. The electrostatic interaction between water molecules was calculated through smooth particle mesh Ewald method. First, we equilibrated a water plug in the single-wall atomistic nanocylinder as a model of nanopore in the fuel cell with radius 1.3nm. Water molecules burst from an interface of the water plug in equilibration. Then, the equilibrium densities both in dense and dilute region ware sampled over 1 ns. The vapor-liquid coexistence line, density profile, free energy profile will be presented in the session.

5:06PM C29.00014 On-demand generation of aqueous two-phase microdroplets with reversible phase transitions , CHARLES COLLIER, Oak Ridge National Laboratory — Aqueous two-phase systems contained within microdroplets enable a bottom-up approach to mimicking the dynamic microcompartmentation of biomaterial that naturally occurs within the cytoplasm of cells. Here, we demonstrate the on-demand generation of femtolitre aqueous two-phase droplets within a microfluidic oil channel. Gated pressure pulses were used to generate individual, stationary two-phase microdroplets with a well-defined time zero for carrying out controlled and sequential phase transformations over time. Reversible phase transitions between single-phase, two-phase, and core-shell microbead states were obtained via evaporation-induced dehydration and on-demand water rehydration. In contrast to other microfluidic aqueous two-phase droplets, which require continuous flows and high-frequency droplet formation, our system enables the controlled isolation and reversible transformation of a single microdroplet and is expected to be useful for future studies in dynamic microcompartmentation and affinity partitioning.

5:18PM C29.00015 H2O and CO2 confined in cement based materials: an ab initio molecular dynamics study with van der Waals interactions , JAMES MORAES DE ALMEIDA, CAETANO RODRIGUES MIRANDA, Universidade Federal do ABC, ADALBERTO FAZZIO, Universidade de São Paulo — Although the cement has been widely used for a long time, very little is known regarding the atomistic mechanism behind its functionality. Particularly, the dynamics of molecular systems at confined nanoporous and water hydration is largely unknown. Here, we study the dynamical and structural properties of H_2O and CO_2 confined between Tobermorite 9Å(T9) surfaces with Car-Parrinello molecular dynamics with and without van der Waals (vdW) interactions, at room temperature. For H_2O confined, we have observed a broadening in the intra and intermolecular bond angle distribution. A shift from an ice-like to a liquid-like infrared spectrum with the inclusion of vdW interactions was observed. The bond distance for the confined CO_2 was increased, followed with the appearance of shorter (larger) intramolecular (intermolecular) angles. These structural modifications result in variations on the CO_2 symmetric stretching Raman active vibration modes. The diffusion coefficient obtained for both confined H_2O and CO_2 were found to be lower than their bulk counterparts. Interestingly, during the water dynamics, a proton exchange between H_2O and the T9 surface was observed. However, for confined CO_2, no chemical reactions or bond breaking were observed.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C30 DPOLY: Polymers and Organic Systems 338 - John Cressman, George Mason University

2:30PM C30.00001 Immobilization of polymer microgels containing metal nanocatalysts onto inorganic surfaces[1] , L. PAPOUTSAKIS, M.A. FRYSALI, M. KALIVA, M. VAMVAKAKI, S.H. ANASTASIADIS, Foundation for Research and Technology-Hellas and Univ. of Crete, Greece — This study is concerned with the attachment of electrostatically and sterically stabilized polymer microgel particles containing either amino (poly(2-(diethylamino)ethyl methacrylate), PDEA) or carboxylic acid (poly(acrylic acid), PAA; poly(methacrylic acid), PMMA) functional groups onto inorganic surfaces. The microgels are prepared by emulsion radical polymerization and are utilized as nanoreactors for the synthesis of metal nanoparticles to be used as nanocatalysts; Pd and Ru nanoparticles have been synthesized. The attachment of the microgel particles onto the various surfaces, which can potentially be used as the walls of microfluidic reactors, is studied; glass, silicon and alumina were used as substrates. We investigated the effects of parameters such as concentration of the suspension, substrate orientation whereas we utilized various recipes for "trapping" the microgel particles within interfaces to achieve their deposition onto the inorganic surfaces. The durability of the microgel particles attached onto the surfaces against hydration and shear forces was tested utilizing repeated immersion of the surfaces into water undergoing mechanically-generated hydrodynamic flow.

2:42PM C30.00002 Predicting Universal Pattern Formation on Spheres with Application to Self-Assembly of Patchy Colloids , ERIK EDLUND, OSKAR LINDGREN, MARTIN NILSSON JACOBI, Chalmers University of Technology — Patchy colloids, colloidal particles with attractive or repulsive patches, serve as a central example of building blocks for self-assembly [1]. The patches can be created using e.g. glancing angle deposition, but recently interest has turned towards using self-assembly for creating the patterns themselves [2]. We present theory for predicting pattern formation of isotropically interacting particles on spheres, based on a relaxation of a Potts-like model who's interactions can be diagonalized (a generalization of the approach in [3]). We give a simplified model of immiscible surfactants on gold nanoparticles[4,5] which we use to demonstrate the theory. We use the theory to design patchy particles for self-assembly of specific geometric structures.

2:54PM C30.00003 Temperature dependent depletion interaction from PEO and other polymers , BEZIA LADERMAN, LANG FENG, STEFANO SACANA, PAUL CHAIKIN, New York University — We have found and tested a depletion mechanism, in which the inter-colloidal attractive interaction can be tuned in an easily accessible temperature range. Usually depletion is considered as a concentration dependent, temperature independent interaction, except when a thermo-sensitive depletent, like Poly-NIPA is used. Our system consists of water, NaCl, micron-size colloids and a polymer depletent. With such solutions colloidal crystals form at room temperature, but as the temperature is increased above a critical point (T_c), we observe the crystals melt and the colloids disperse. The process is thermo-reversible since crystals reform in a few minutes after the temperature is tuned below T_c. We studied the dependence of the critical temperature T_c on factors such as the ionic strength, component/surface chemistry of the particle, type of depletent and additional non-ionic surfactants. Since the gyration radius of the depletent used in this study does not vary significantly with temperature, we argue that a temperature dependent adsorption of polymer depletent on the colloidal surface is responsible for the observed phase transition. Given the generality of the components used, our finding is useful for directed or self-assembly on the colloidal scale.

3:06PM C30.00004 Modeling two-dimensional materials self-assembly: from Honeycomb to Kagome lattices , SIMISO K. MKHONTA, Wayne State University, KEN R. ELDER, Oakland University, ZHI-FENG HUANG, Wayne State University — Novel two-dimensional materials of graphene-type and beyond have been of great interest in both fundamental research and a wide range of applications. In this work we study the self assembly properties of these 2D structures via the development of a phase-field-crystal model. The free energy functional in the model is designed to favor self assembly in crystals commensurate with a triangular symmetry, leading to a range of complex phases including honeycomb, kagome, and oblique, in addition to the simple triangular phase. We also examine the elastic properties of these novel crystalline structures, and the nonequilibrium evolution processes of these systems which are governed by diffusive time-scale dynamics.

3:18PM C30.00005 Stochastic self-assembly of incommensurate clusters[1] , MARIA D'ORSOGNA, CalState-Northridge, GREG LAKATOS, Zymeworks, Inc., TOM CHOU, UCLA — We examine the classic problem of homogeneous nucleation and self-assembly by deriving and analyzing a fully discrete stochastic master equation. We enumerate the highest probability steady-states, and derive exact analytical formulae for quenched and equilibrium mean cluster size distributions. Upon comparison with results obtained from the associated the mass-action Becker-Döring (BD) equations, we find striking differences between the two corresponding equilibrium mean cluster concentrations. These differences depend primarily on the divisibility of the total available mass by the maximum allowed cluster size, and the remainder. When such mass "incommensurability" arises, a single remainder particle can "emulsify" the system by significantly broadening the equilibrium mean cluster size distribution. This discreteness-induced broadening effect is periodic in the total mass of the system but arises even when the system size is asymptotically large, provided the ratio of the total mass to the maximum cluster size is finite. Our findings define a new scaling regime in which results from classic mass-action theories are qualitatively inaccurate, even in the limit of large total system size.

3:30PM C30.00006 Ultra-soft 100 nm thick zero Poisson's ratio film with 60% reversible compressibility , CHIEU NGUYEN, STEVE SZALEWSKI, RAVI SARAF, None — Squeezing films of most solids, liquids and granular materials causes dilation in the lateral dimension which is characterized by a positive Poisson's ratio. Auxetic materials, such as, special foams, crumpled graphite, zeolites, spectrin/actin membrane, and carbon nanotube laminates shrink, i.e., their Poisson's ratio is negative. As a result of Poisson's effect, the force to squeeze an amorphous material, such as a viscous thin film coating adhered to rigid surface increases by over million fold as the thickness decreases from 10 μm to 100 nm due to constrain on lateral deformations and off-plane relaxation. We demonstrate, ultra-soft, 100 nm films of polymer/nanoparticle composite adhered to 1.25 cm diameter glass that can be reversibly squeezed over 60% strain between rigid plates requiring (very) low stresses below 100 KPa. Unlike non-zero Poisson's ratio materials, stiffness decreases with thickness, and the stress distribution is uniform over the film as mapped electro-optically. The high deformability at very low stresses is explained by considering reentrant cellular structure found in cork and the wings of beetles that have Poisson's ratio near zero.

3:42PM C30.00007 Inferring elastic properties of an fcc crystal from displacement correlations: sub-space projection and statistical artifacts , ASAD HASAN, CRAIG MALONEY, Carnegie Mellon University — We compute the effective dispersion and density of states (DOS) of two-dimensional sub-regions of three dimensional face centered cubic (FCC) crystals with both a direct projection-inversion technique and a Monte Carlo simulation based on a common Hamiltonian. We study sub-regions of both (111) and (100) planes. For any direction of wavevector, we show an anomalous $\omega^2 \sim q$ scaling regime at low q where ω^2 is the energy associated with a mode of wavenumber q. This scaling should give rise to an anomalous DOS, D_ω, at low ω: $D_\omega \sim \omega^3$ rather than the conventional Debye result: $D_\omega \sim \omega^2$. The DOS for the (100) sub-region looks to be consistent with $D_\omega \sim \omega^3$, while the (111) shows something closer to the Debye result at the smallest frequencies. Our Monte Carlo simulation shows that *finite sampling* artifacts act as an effective disorder and bias the D_ω in the same way as the *finite size* artifacts, giving a behavior closer to $D_\omega \sim \omega^2$ than $D_\omega \sim \omega^3$. These results should have an important impact on interpretation of recent studies of colloidal solids where two-point displacement correlations can be obtained in real-space via microscopy.

3:54PM C30.00008 Measuring colloidal osmotic compressibility of a polymer-crowded colloidal suspension by optical trapping , JINXIN FU, VURAL KARA, H. DANIEL OU-YANG, Lehigh University — Particle interactions determine the stability of nanoparticle suspensions and the phase separation of particle-polymer mixtures. However, due to the small sizes of the dispersed nanoparticles, it is not easy to directly measure interaction forces between particles in a colloidal suspension. In this paper, we propose an "Optical Bottle" approach to quantify these particle interactions in a suspension by measuring the colloidal osmotic compressibility of the nanoparticles. Virial expansion of the colloidal osmotic compressibility yields virial coefficients of different orders. The second order virial coefficient of aqueous suspensions of colloidal polystyrene nanospheres in the presence of high-salt (KCl) and polyethylene glycol (PEG) is found to decrease with increasing PEG concentration, suggesting an attractive depletion interaction between the PEG-crowed polystyrene particles.

4:06PM C30.00009 The impact of surface properties on particle-interface interactions , ANNA WANG, Harvard University, School of Engineering and Applied Sciences, DAVID KAZ, University of California, Berkeley, RYAN MCGORTY, University of California, San Francisco, VINOTHAN N. MANOHARAN, Harvard University, School of Engineering and Applied Sciences and Department of Physics — The propensity for particles to bind to oil-water interfaces was first noted by Ramsden and Pickering over a century ago, and has been attributed to the huge reduction in surface energy when a particle breaches an oil-water interface and straddles it at its equilibrium height. Since then materials on a variety of length scales have been fabricated using particles at interfaces, from Pickering emulsions to Janus particles. In these applications, it is simply assumed that the particle sits at its hugely energetically favourable equilibrium position. However, it was recently shown that the relaxation of particles towards their equilibrium position is logarithmic in time and could take months, much longer than typical experiments. Here we investigate how surface charge and particle 'hairiness' impact the interaction between micron-sized particles and oil-water interfaces, and explore a molecular kinetic theory model to help understand these results. We use digital holographic microscopy to track micron-sized particles as they approach an oil-water interface with a resolution of 2 nm in all three dimensions at up to thousands of frames per second.

4:18PM C30.00010 Wavefront Kinetics of Plamsa Oxidation of Polydimethylsiloxane: Implications for Micropatterning Size Limits by Wrinkling[1] , ANGUS BAYLEY, JOAO CABRAL, JOANNE LINGLING LIAO, Imperial College London, ARNAUD CHICHE, DSM Material Science Centre, PAUL STAVRINOU, Imperial College London — We investigate spontaneous wrinkling of bilayers under compressive strain as a means of producing highly ordered micropatterns that span macroscopic areas. Our focus is a fast track wrinkling method, involving plasma oxidation of pre-stretched elastomeric polydimethylsiloxane (PDMS), which when subsequently relaxed forms one-dimensionally aligned sinusoidal surface undulations. For the first time, we evaluate this micropatterning method in terms of the range of geometries of 1D wrinkles it can produce. Our investigation reveals the presence of an apparent minimum wrinkling wavelength for a given value of prestrain (approximately 600nm for a prestrain of 10%), offering clues regarding the kinetics of glassy film formation on the surface of PDMS during plasma oxidation, which is subsequently investigated. X-ray reflectometry and analysis of wrinkling behavior for a selection of PDMS samples exposed to a range of plasma doses yields evidence that this transient film growth process is not dissimilar to the process of frontal photopolymerization. With the benefit of this finding, a route to further minimization of wrinkle periodicity - increasing processing pre-strain - is identified and subsequently implemented, allowing us to access periodicities as low as 140nm.

[1]We acknowledge the EPSRC for their funding of this work.

4:30PM C30.00011 Novel low temperature phase transitions in short grafted chains as a model for monolayers of amphiphile molecules with ionic heads[1] , CARLOS GONZALEZ-CASTRO, GUILLERMO RAMIREZ-SANTIAGO, Instituto de Fisica, Universidad Nacional Autonoma de Mexico — We have carried out extensive Monte Carlo simulations in the NPT ensemble of a model for Langmuir monolayers of amphiphile molecules with ionic heads deposited on an interface. We considered a previously proposed coarse–grained model [1] in which the molecules are represented as short chains made up of beads with one slightly larger head confined at the interface. By analyzing the behavior of several order parameters as a function of temperature and pressure we obtained a liquid expanded phase and various ordered condensed phases with different molecular tilts. More importantly, we found a novel "untilted" to "collective tilted" to "small correlated tilted" phase transition at low temperatures, and different pressure values, as suggested by the behavior of two order parameters. One that measures the average molecular inclination and the other that measures the average projection on the x–y plane of the vector that joins the head center with the last monomer center of each molecule. The latter yields information about the correlation of the molecular tilt.

4:42PM C30.00012 Optical conveyors: Active tractor beams for colloids, emulsions and aerosols , DAVID RUFFNER, DAVID GRIER, New York University — A tractor beam is a travelling wave that transports material back to its source. We experimentally demonstrate such a beam by coherently superposing coaxial Bessel beams. These optical conveyors have periodic intensity variations along their axes that act as highly effective optical traps for micrometer-scale objects. Varying the Bessel beams' relative phase shifts the traps axially and thereby selectively transports trapped objects either downstream or upstream along the length of the beam. The same methods used to project a single optical conveyor can project arrays of independent optical conveyors, allowing bidirectional motion. This opens up new possibilities for three dimensional transport of colloids, emulsion droplets and aerosol particles with sub-micrometer resolution over ranges extending to 50 micrometers and potentially beyond.

4:54PM C30.00013 Robust thermosensitive colloidal photonic crystals , JIN-GYU PARK, WILLIAM ROGERS, SOFIA MAGKIRIADOU, YOUNG-SEOK KIM, VINOTHAN MANOHARAN, Harvard University, HARVARD UNIVERSITY TEAM, KOREA ELECTRONICS TECHNOLOGY INSTITUTE COLLABORATION — Photonic structures made of colloidal nanoparticles that show dynamic switching have tremendous potential applications including tunable lasers, biological/chemical sensors, and optical devices. As a building block, hydrogel nanoparticles made of poly(N-isopropylacrylamide)(pNiPAm) are particularly interesting due to their tunability in size with response to temperature. Uses of pNiPAm as a 3-dimensional building block in colloidal arrays, however, are strictly limited because the structures are easily destroyed by increased thermal fluctuations around their volume phase transition temperature. Here we demonstrate a simple and robust way to assemble photonic crystals made of soft pNiPAm colloidal particles. Our particles consist of a polystyrene core and transparent p(NiPAm-co-Acrylic acid) shell. The scattering is therefore dominated by the polystyrene core, yet the inter-scatterer distance is tunable with temperature change. We use depletion attraction to assemble the colloidal particles into 3D photonic crystals. The resulting structures show dynamic modulations of stop-bands from 24C to 70C without losing the structural features.

5:06PM C30.00014 ABSTRACT WITHDRAWN –

5:18PM C30.00015 On Ulam's packing conjecture: is the ball the worst shape for packing? , YOAV KALLUS, Princeton University — The question of which convex shapes leave the most empty space in their densest packing is the subject of Reinhardt's conjecture in two dimensions and Ulam's conjecture in three dimensions. In two dimensions, a regular octagon whose corners have been smoothed to arcs of hyperbolas is known to be a local minimum of the optimal packing fraction and the circle is known to not be a local minimum. In three dimensions, we show that the ball is a local minimum: it is the worst packing shape among shapes of sufficiently low asphericity. We also discuss related results in higher dimensions and for the worst shape for other optimal arrangement problems.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C31 DPOLY: Polymeric Elastomers and Gels 339 - Jens Glaser, University of Minnesota

2:30PM C31.00001 How water content determines small-molecule mobility in hydrogels , SUNG CHUL BAE, AH-YOUNG JEE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Surprisingly little is known from quantitative physical study about dynamics within hydrogels, in spite of the fundamental importance of solvent concentration in the theory and application of nonpolar polymer gels. We have prepared model hydrogels of different kinds and studied the diffusion within them of fluorescently-labeled solutes. Comparison of translational and rotational diffusion shows remarkable dependence, on water content, of translation-rotation correlations.

2:42PM C31.00002 Unexpected water screening in gel-encapsulated terbium systems , TETYANA IGNATOVA, Lehigh University, JUAN G. DUQUE, STEPHEN K. DOORN, Los Alamos National Laboratory, SLAVA V. ROTKIN, Lehigh University — Terbium (Tb) salts and their compounds are used as bio-labels and dyes due to their unique photoluminescence (PL) properties. Our study focuses on PL of Tb ions in crowded surroundings, mimic to living cells. Silica gel with SWNT dispersed with sodium deoxycholate (DOC), silica gel only, and DOC water solution were chosen as prototypes for bio-environment. Time resolved and steady state spectroscopy was used to monitor the behavior of terbium in different enclosing. We observed significant increase of PL lifetime in the gel in comparison with aqua solution, which indicates the reduction of OH groups in the co-ordination shell of the Tb ion. PL spectra of Tb in water and in DOC micelles and gels confirmed structural changes during encapsulation process.

2:54PM C31.00003 Molecular origins of reinforcement in responsively nanostructured, shear thinning double network hydrogels , MATTHEW GLASSMAN, Massachusetts Institute of Technology, JACQUELINE CHAN, California Institute of Technology, BRADLEY OLSEN, Massachusetts Institute of Technology — Triblock copolymers containing associative protein midblocks and thermoresponsive endblocks have recently been shown to form reinforceable, nanostructured hydrogels. Triggered self-assembly of orthogonal physical crosslinks causes a reversible transition from a shear thinning material at low temperatures to a toughened state at high temperatures with resistance to creep, erosion, and failure in uniaxial compression. In this study, properties of the individual networks were varied to investigate the relationships among association density in the protein network, nanostructure formation, and ultimate mechanical reinforcement that could be realized in this double network architecture. Through a broad survey of materials, large changes in static and dynamic mechanical properties were identified, some leading to a 14-fold increase in plateau modulus and a decrease in creep compliance by more than two orders of magnitude over the range from 5-50^{o}C. Detailed investigation of the structure and relaxation behavior of the underlying network of micelles with associative coronae reveals important parameter constraints for achieving high performance in these double network gels.

3:06PM C31.00004 ABSTRACT WITHDRAWN –

3:18PM C31.00005 Large-amplitude oscillatory shear of methylcellulose solutions through the sol-gel transition , JOHN W. MCALLISTER, JOSEPH R. LOTT, FRANK S. BATES, TIM P. LODGE, University of Minnesota — Methylcellulose (MC) is a chemically modified polysaccharide that is partially substituted by methoxy groups. Aqueous MC solutions undergo gelation and phase separation (LCST) upon heating, which is attributed to the assembly of molecules into fibrillar structures noted by cryo TEM images and small angle neutron scattering. The transition from a strain-softening solution to a strain hardening gel upon heating has been probed using large-amplitude oscillatory shear (LAOS). In addition to strain hardening, MC solutions exhibit positive normal stresses (pressing the plates of the rheometer apart) while MC gels exhibit negative normal stresses (contracting the plates together) at stresses larger than 10 Pa. Nonlinear rheological responses are a useful probe to monitor structure-property relationships as MC transitions from a solution to a gel.

3:30PM C31.00006 Analysis of the biaxial stretching of Tetra-PEG gel , TAKUYA KATASHIMA, UNG-IL CHUNG, TAKAMASA SAKAI, School of Engineering, The University of Tokyo, KENJI URAYAMA, Department of Materials Chemistry, Kyoto University — Non-linear stress-strain relationships that elastomers exhibit are governed by the strain energy density function (W). Although many types of W models were examined, full understanding of W still remains incomplete due to the two problems; the limitation in deformation range and the inhomogeneities in polymer networks. In this study, we perform various types of biaxial stretching for Tetra-PEG gels, which is a near-ideal network. We found that (1) the Neo Hookean (NH) model, which has been considered as a model for ideal networks, fails to describe the biaxial date; (2) the stress ratio σ_{y} / σ_{x} (where x and y are the stretching and constrained directions, respectively) in pure shear is larger than the expectation of the models with no strain-coupling term, and σ_{y} / σ_{x} increases with an increase in polymer fraction. These results indicate that the two effects, i.e., finite extensibility and strain-coupling should be introduced in W. We extend the Gent model, which considers the finite extensibility on the basis of the NH model, by adding a linear I_2 term. This model successfully describes the whole data with all fractions.

3:42PM C31.00007 Low Modulus Silicone Elastomer Networks with Desirable Viscoelastic Properties for Cell Mobility Studies , JULIE N. L. ALBERT, JAN GENZER, North Carolina State University, Chemical and Biomolecular Engineering — Biocompatible silicone elastomer networks provide a versatile platform for studying the effect of compliance on cell movement. In conventional network formation schemes, poly(dimethylsiloxane) (PDMS) is cross-linked via reactive end groups, and the modulus of the material is controlled by the ratio of polymer to cross-linker. However, low modulus networks fabricated in this manner are imperfect and insufficiently cross-linked with high soluble fractions and reduced elasticity, especially as the network modulus approaches that of soft tissues (on the order of 10 kPa). In order to overcome these limitations, we synthesized PDMS chains in which vinylmethylsiloxane units were incorporated every ≈15-20 kDa along the polymer backbone. We then cross-linked the polymer through the vinyl groups using hydrosilylation chemistry. The resultant networks exhibited lower soluble fractions and lower viscous dissipation/greater elasticity as compared to equivalent-modulus networks fabricated by the conventional end-group cross-linking scheme. We attribute the mechanical properties of our networks to the presence of network-bound free chain ends that effectively plasticize the network to lower the modulus without compromising network elasticity.

3:54PM C31.00008 Coarse grain modeling of imperfect networks and gels , YELENA SLIOZBERG, TANYA CHANTAWANSRI, TIMOTHY SIRK, JAN ANDZELM, RANDY MROZEK, JOSEPH LENHART, U.S. Army Research Laboratory — There is a strong interest in chemically and physically cross-linked entangled polymer networks and gels due to their tailorability in respect to both mechanical and structural properties. Even so, these properties are sensitive to imperfections in the polymer networks, such as dangling ends and loops. Computational modeling is a viable tool to understand the effects of these imperfections on properties in a controlled environment, in which specific defects can be systematically created and varied. In this study, we have employed generic bead-spring models of flexible chains to study a chemically and physically cross-linked network. Our results will show the importance defects, such as dangling ends and loops, on the mechanical and structural properties of these networks. We will also discuss the effects of these defects on the time-dependent elastic modulus. The simulation results qualitatively agree with experimental results and the other theoretical predictions.

4:06PM C31.00009 The Interesting Influence of Nanosprings on the Viscoelasticity of Elastomeric Polymer Materials: Simulation and Experiment , JUN LIU, LIQUN ZHANG, DAPENG CAO, Beijing University of Chemical Technology, Beijing, China — Among all carbon nano-structured materials, helical nanosprings or nanocoils have attracted particular interest. Here, carbon nanosprings are directed to adjust the viscoelasticity and reduce the resulting hysteresis loss (HL) of elastomeric polymer materials. Two kinds of nanosprings filled elastomer composites are constructed: system I is obtained by directly blending polymer chains with nanosprings, while system II is composed of the self-assembly of the tri-block structure (chain-nanospring-chain). Through coarse-grained molecular dynamics simulation, we find that the incorporation of nanosprings prominently improve the mechanical strength of the elastomer matrix, and importantly, decrease considerably the hysteresis loss. Furthermore, the spring constant of nanosprings and the interfacial chemical coupling between chains and nanosprings both play a crucial role. It is inferred that elastomer/carbon nano-structured materials with good flexibility and reversible mechanical response (nanosprings, nanocoils, nanorings and thin graphene sheet) may possess both excellent mechanical and low HL properties, which could open a new avenue to fabricate high performance automobile tires, and facilitate the large-scale industrial application of these materials.

4:18PM C31.00010 High-Strain Rate Mechanical Response of Cured Epoxy Networks , TIMOTHY SIRK, Army Research Laboratory, KETAN KHARE, MIR KARIM, Texas Tech University, JOSEPH LENHART, Army Research Laboratory, RAJESH KHARE, Texas Tech University, JAN ANDZELM, Army Research Laboratory — Chemically cross-linked polymer networks are increasingly common in high performance composites, adhesives and other applications involving high-impact loading conditions or ballistic collisions. The mechanical behavior of epoxy and other polymer networks exhibit a strong dependence on strain rate near the glass transition temperature (Tg); however, the elastic modulus at strain rates greater than 10^5 1/s is difficult to capture with experimental techniques. We present computational results of Di-Glycidyl Ether of Bisphenol A (DGEBA) and Jeffamine diamines (D230) from molecular dynamics simulation, which is intrinsically well-suited to model material deformation at high strain rates. Our results show that the experimental Tg can be reproduced from molecular dynamics, and the Williams-Landel-Ferry equation is useful in rationalizing the shift of Tg due to fast annealing and high strain rates. Temperature sweeps of elastic modulus show the glass-rubber transition to occur over a significantly wider temperature range compared with experimental measurements at low strain rates.

4:30PM C31.00011 Mechanical and Thermal Properties of Cross-Linked Phenolic Resins Using Molecular Dynamics , JOHN LAWSON, JOSHUA MONK, JUSTIN HASKINS, CHARLES BAUSCHLICHER, NASA Ames Research Center — To gain insight into the design of materials, it is valuable to understand how the chemical make-up at the nano-scale can influence the thermal and mechanical bulk properties. An atomistic computational study allows us to manipulate the structural make-up of individual phenolic chains as well as generate various cross-linked (or cured) systems. In this study, molecular dynamics simulations of bulk phenolic systems were performed with the software LAMMPS. An all-atom force field was chosen to investigate how the strength and thermal conductivity of the phenolic material varies as a function of the degree of cross-linking and chemical make-up of the phenolic chains. Small-scale mechanical tests were performed to compute various moduli for the phenolic systems above and below the glass transition at varied degrees of cross-linking. The thermal conductivity was obtained using the Green-Kubo approach for the virgin phenolic system as well as the strained systems.

4:42PM C31.00012 Investigation of the Melting Point Depression of 12-Hydroxystearic Acid Organogels Using the Flory Diluent Model , KEVIN CAVICCHI, BRIAN LIPOWSKI, University of Akron — This talk will focus on the gelation behavior of 12-hydroxystearic acid (12-HSA) in organic solvents. Thermo-reversible gelation occurs by crystallization of 12-HSA in organic solvent to form 3-D fibrillar networks. The melting point vs. composition for 12-HSA in a range of solvents has been measured. The liquidus lines could be fit with the Flory-diluent model that takes into account the non-ideal free energy of mixing and the disparity in the size of the solvent and 12-HSA molecules. The fits indicated that the effective molar volume of 12-HSA increased as the hydrogen bonding Hansen solubility parameter δ_{h} of the solvent decreased. This is attributed to the hydrogen-bonding driven aggregation of the 12-HSA in the liquid state based on previous observations that 12-HSA forms aggregated structures in non-polar solvents (e.g. dimers and tetrameters). These results indicate that the stabilization of the solid phase in 12-HSA solutions has contributions from both variations in the entropy of mixing as well the enthalpy of mixing. The importance of both these factors for designing small molecule gelators will be discussed.

4:54PM C31.00013 Structural analysis and mechanical properties of syndiotactic polypropylene (sPP) gels formed at different cooling temperatures , KEITA TAKAESU, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The effects of the cooling temperature on the mechanical properties and the microstructure of the syndiotactic polypropylene (sPP) gel were investigated. sPP/decahydronaphthalene gels were prepared at different cooling temperatures followed by the compression testing to evaluate the mechanical properties. To analyze the microstructure of the gels, optical microscopy observation, differential scanning calorimetry (DSC) analysis, Fourier transform infrared spectroscopy (FTIR) analysis, and small angle X-ray scattering (SAXS) analysis were carried out. It was found that the sPP gel prepared at the lowest cooling temperature using liquid nitrogen (named Gel LN) showed highest mechanical properties. The sPP gels cooled at relatively high temperatures of 38^{o}C (Gel 38), 25^{o}C (Gel 25), and 0^{o}C (Gel 0) became more brittle. DSC analysis and FTIR analysis revealed that the crystal amount, which acted as the crosslinking points of sPP gels, of Gel LN was largest among other sPP gels. In addition, SAXS analysis suggested that the size of each crystalline domain in Gel LN was about 15 nm. It was concluded from these results, that Gel LN exhibited the highest mechanical properties due to its homogeneous and dense crystalline network structures.

5:06PM C31.00014 Mechanical Measurement of Gels: Pre-stress and Failure , SAMI FAKHOURI, SHELBY HUTCHENS, ALFRED CROSBY, University of Massachusetts Polymer Science and Engineering — A recently developed technique, Cavitation Rheology (CR), provides a means of measuring the mechanical properties of soft materials on length scales from ~ 0.1 μm to mm at a specific location. CR involves inflation of a small bubble at the tip of a syringe needle which has been inserted into a material. After insertion, the pressure in the syringe is raised until a critical point where the material fails, resulting in rapid inflation of a cavity at the syringe tip. The critical pressure for failure can provide information about the materials properties of the system such as the elastic modulus, E, the critical strain energy release rate, G_c, and the surface energy, γ. Modulus measurements by CR have been made in many synthetic gels and biological tissues with similar accuracy to shear rheology. However, as CR requires insertion of a needle into the subject material, measurements are inherently made in a pre-stressed state. In this work, we have examined the pre-stress associated with needle insertion and the influence of this stress on failure in a synthetic gel of PMMA-PnBA-PMMA triblock copolymer in 2-ethylhexanol.

5:18PM C31.00015 First and second order volume-phase transitions in photo-cross-linked poly(cyclopropylacrylamide) and poly(N-vinylisobutyramide) coatings , RYAN TOOMEY, LEENA PATRA, University of South Florida — The temperature-dependent swelling of thin (100 nm) coatings of photo-cross-linked poly(cyclopropylacrylamide), or poly(CPAAm), and poly(vinylisobutyramide), or poly(NVIBAm) was characterized. Both polymers contained 3 mole% of methacroylaminobenzophenone (MnBP) as the photo cross-linking unit. Poly(CPAAm-co-MnBP) showed a continuous, 2nd order deswelling transition between 10 and 70 °C with no hysteresis. Poly(NVIBAm-co-MnBP), on the other hand showed a discontinuous, 1st order deswelling transition at 45 °C with hysteresis. The differences in the swelling transitions can be interpreted within the context of the cloud-point measurements of the uncross-linked polymers. Whereas poly(NVIBAm-co-MnBP) has a significant off-zero critical point ($>$ 10 wt% polymer) at 36 °C, poly(CPAAm-co-MnBP) has a critical point at zero concentration and 23 °C. Concurrent measurements of the infrared vibrations of the amide groups in both polymers further revealed that the amide group in poly(CPAAm-co-MnBP) maintains a constant hydrogen-bonding environment throughout the volume-phase transition. Poly(NVIBAm-co-MnBP), on the other hand, has a concentration-dependent hydrogen bonding environment around the carbonyl group, which is consistent with an off-zero concentration in the cloud point curve.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C32 DPOLY: Polymer Nanocomposites I 340 - Venkat Ganesan, University of Texas at Austin

2:30PM C32.00001 Mechanical Properties of Cross-linked Epoxy - Carbon Nanotube Nanocomposites: Effect of Interfacial Interactions and Nanoconfinement , KETAN KHARE, RAJESH KHARE, Department of Chemical Engineering, Texas Tech University — The effect of fillers on polymer nanocomposites is conceptually analogous to the effect of nanoconfinement of polymers by solid substrates. This assertion is tested in our work by studying the volumetric, structural, dynamic, and mechanical properties of nanocomposites of cross-linked epoxy and carbon nanotubes (CNTs) using molecular simulations. We use atomistically detailed models in our simulations, which allow us to explicitly account for the specific chemical interactions between the filler and the matrix. Our results show that the poor interfacial interactions between the filler and the matrix lead to a tendency for depression in the glass transition temperature (T_g) of the nanocomposite compared to the neat cross-linked epoxy. Functionalization of CNTs is expected to strengthen interfacial interactions between the filler and the polymer matrix, and thus can have a strong impact on the properties of the nanocomposite. The relationship between the T_g, molecular dynamics, and the mechanical properties of the nanocomposites can be non-intuitive. Results will be presented for the relationship between mechanical properties, molecular dynamics, and the T_g of nanocomposites of cross-linked epoxy containing both, pristine and functionalized CNTs.

2:42PM C32.00002 Effect of Grafting Density and Curvature of Nanoparticle on Mechanical Properties of Polymer Nanocomposite , HUIKUAN CHAO, ROBERT RIGGLEMAN, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — Polymer nanocomposites (PNCs) are materials obtained by dispersing nanoparticles in a polymer matrix. Due to the large surface-to-volume ratio between the nanoparticles and the polymer, substantial enhancement in dynamic and mechanical properties can be observed for relatively low concentrations of particles. One common approach for ensuring dispersion of the nanoparticles is to end-graft polymers that are miscible in the host polymer matrix to the surface of the nanoparticles in the PNC. In many applications, understanding the role that the nanoparticles with grafted chains have on the resulting mechanical properties of the PNC will be of central importance in the final applications as well as the processing of the original sample. In this talk, I will first introduce the coarse grain model we used to study various mechanical properties of polymer and PNC. By designing a model system where the nanoparticles with different radii are remain dispersed whether they are grafted with polymer chains or not, we are able to isolate the role that chain grafting has on various aspects of the mechanical response of the PNC. We provide a detailed picture of how the elastic constants, yield stress, and the strain hardening behaviors depend on the grafting density and the size of nanoparticles

2:54PM C32.00003 Mechanical properties of homogeneous nanofiber composites fabricated by electrospinning , KENTARO WATANABE, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — A new composite that possesses uniformly dispersed polymeric nanofibers in different polymeric matrix was introduced by using electrospinning. Recently, nanofibers have been actively investigated for fillers for polymeric nano-composites to enhance the mechanical properties of the composites or to get highly functionalize polymer materials. Polyvinyl alcohol (PVA) nanofibers were selected as polymeric fillers and polydimethylsiloxane (PDMS) was used for polymeric matrix. Internally well-dispersed composites were fabricated by this new method, whereas rather anisotropic composites were also made by the traditional sandwich method. The morphology of the composites was analyzed by field emission scanning electron microscopy (FE-SEM). It was found that, in the new internally well-dispersed composites, PVA nanofibers existed from the both surfaces of the polymer matrix, uniformly dispersed in the composite. Isotropic mechanical properties were observed for internally well-dispersed composites, whereas relatively anisotropic characteristics could be observed for the traditionally-made composites.

3:06PM C32.00004 Nanoparticle synergies in modifying thermal conductivity for heat exchanger in condensing boilers[1] , KAI YANG, SHAN HE, Stony Brook University, THOMAS BUTCHER, REBECCA TROJANOWSKI, Brookhaven National Laboratory, NING SUN, DILIP GERSAPPE, MIRIAM RAFAILOVICH, Stony Brook University — The heat exchanger we are using for condensing boilers is mainly made from aluminum alloys and stainless steel. However, the metal is relatively expensive and corrosion together with maintenance is also a big problem. Therefore, we have developed a new design and material which contain carbon black, carbon nanotube, aluminum oxide and graphene as additives in polypropylene. When multiple types of particles can be melt blended simultaneously and synergies can be achieved, imparting particles to the nanocomposite, achieved much higher thermal conductivity rather than single additive. Here we show the flame retardant nanocomposite which can pass the UL-94-V0 vertical burning test, perform nice in Cone Calorimetry Test and has relatively good mechanical properties. SEM images of the blend show that the Carbon nanobute and other additives well dispersed within the polymer matrix which match our computational calculation for getting the percolation to achieve thermal conductivity around 1.5W/m·K rather than 0.23W/m·K as pure polypropylene.

3:18PM C32.00005 Molecular Dynamics Simulations on the Mechanical Properties of Blend of Polymer and Polymer Grafted Nanoparticles , DONG MENG, SANAT KUMAR, Columbia University, GARY GREST, Sandia National Laboratories, TING GE, MARK ROBBINS, The Johns Hopkins University — Grafting polymers onto the surface of NPs has become one of the most effective approaches to integrate NPs into polymer melts. It then becomes crucial to be able to understand the mechanical properties of the resulting composites. Using molecular dynamics simulations we investigated how the presence of grafted NPs changes mechanical responses of an entangled polymer matrix below its glass transition temperature under uniaxial tensile deformation. It is found that comparing to neat polymer melts adding fillers slightly increases the elastic modulus as well as the yielding stress of the composites. But changes in the fracture work (total work needed to pull samples to failure) are every dependent on the loading fraction and dispersion state of NPs in polymer matrix. At small loadings fracture work is found to be significantly reduced due to polymer crazing around NPs, which is induced by local triaxial stresses, while at higher loadings a big degree of enhancement is observed because of network forming among grafted NPs.

3:30PM C32.00006 Revealed nano-architecture and dynamics of bound polymer layers on nanofillers[1] , TADANORI KOGA, NAISHENG JIANG, MAYA ENDOH, Stony Brook University, TOMOMI MASUI, HIROYUKI KISHIMOTO, Sumitomo Rubber Industries, TAKASHI TANIGUCHI, Kyoto University, HIROSHI WATANABE, Institute for Chemical Research, Kyoto University, MICHIHIRO NAGAO, Center for Neutron Research, NIST — It is known that the physical properties of adsorbed polymers on solids are often different from those of bulks. However, the mechanism associated with the structure and dynamics at the polymer/solid interfaces still remains unsolved, primarily due to the lack of suitable experimental tools. Recently, we used small-angle neutron scattering and neutron spin-echo spectroscopy which allow us to highlight adsorbed polymers on nanofillers with deuterated labeling. The system used was polybutadiene (PB) adsorbed on carbon black (CB) fillers in toluene. The CB (80 nm in diameter) was compounded into PB by using a Banbury mixer. The CB/PB compound was then dissolved in toluene, until the weight of the compound remained unchanged. To label the resultant un-dissolved PB layer on CB (i.e., about 3 nm in thickness based on TEM analysis) for the neutron scattering experiments, deuterated toluene, which has the nearly same scattering length density as that of CB, was used. We will highlight the unique structure and dynamics of the bound PB layer by comparing with a PB brush grafted on CB and further discuss geometric effects of solids (curvature or flat) on the nano-architectures at the polymer/solid interfaces.

3:42PM C32.00007 Studying the effect of the curvature of a polymer-grafted nanoparticle surface on equilibrium brush dimensions via small-angle neutron scattering (SANS) and polymer field theory , MICHAEL J. A. HORE, BOUALEM HAMMOUDA, National Institute of Standards and Technology — For polymer-grafted nanoparticles with a size that is on the order of the radius of gyration of the polymer chains, the curvature of the nanoparticle surface has a role in determining the equilibrium brush structure. The curvature can cause an increase in the conformational entropy of the brush chains relative to that of a flat surface, and hence has large implications for dispersion of nanoparticles within a polymer matrix. Here, small-angle neutron scattering (SANS) is performed to measure the radius of gyration of a poly(ethylene glycol) (PEG) brush that is grafted to the surface of gold nanorods (diameter x length: 10 x 30 nm) and nanospheres (diameter: 10 nm) in both solution and a within a polymer melt. To help interpret the SANS measurements, field theoretic simulations are employed to calculate density profiles for the brush polymer in solution and a polymer melt as a function of nanoparticle shape, radius, and brush grafting density .

3:54PM C32.00008 An interface controlled dynamic stiffening in polymer nanocomposites , ERKAN SENSES, PINAR AKCORA, Stevens Institute of Technology — Tunable interfaces between inorganic and organic phases determine the mechanical behavior of responsive and adaptive composites. We present that bonding/debonding of chains on nanoparticles can be modulated with extensive periodic strains. Mechanical response of an attractive model polymer composite, poly(methyl methacrylate) filled with silica nanoparticles of sizes 13 nm and 56 nm, is monitored in series of deformation-resting experiments allowing us to tune the interfacial strength of polymer. We show that this deformation process exhibit unusual stiffening of composites as the matrix polymer is bound to the surface stronger on removal of strain. Mechanical response during the recovery together with SANS and FTIR analysis of the composites at different states of deformation reveal that this behavior arises from enhancement in the entanglement of chains at interfaces. We studied the effects of strain amplitude, confinement parameter (ID/2Rg) and resting time and found that the stiffening is manifest only after large strains. This behavior offers an 'on demand' reinforcement properties to polymer nanocomposites, implying that the composites with attractive interfaces can self-stiffen as needed.

4:06PM C32.00009 Thermoplastic Elastomers via polyolefin/Layered Silicate Nanocomposites , SRI HARSHA KALLURU, ERIC W. COCHRAN, Iowa State University, Ames, IA — Here we report the synthesis of fully exfoliated polyolefin nanocomposites via Surface-Initiated Ring Opening Metathesis Polymerization (SI-ROMP). Montmorillonite (MMT) clay platelets were rendered hydrophobic through ion exchange with alkyl-ammonium surfactants terminated with norbornene. We were then able to form block copolymer brushes of (substituted) norbornenes and cyclopentene via SI-ROMP. Subsequent hydrogenation yielded highly crystalline polyethylene and rubbery saturated polynorbornenes, thus giving a thermoplastic elastomer. Nanocomposites were prepared with different nanofiller percentages and were characterized for morphological (XRD, TEM), thermal (TGA, DSC), and mechanical (DMA, Rheology) properties. Complete exfoliation of nanocomposites was confirmed by XRD and TEM. A fraction of the polymer brushes were subsequently removed from their substrate by reverse ion exchange and characterized in parallel with their corresponding nanocomposite analogs. In this way we were able to directly assess the role of the filler particle in the thermal properties, melt rheology, morphology, and tensile properties.

4:18PM C32.00010 Bound layer in polymer nanocomposites: nanoparticle size dependence and solvent effect , NICOLAS JOUAULT, JOSEPH MOLL, DAN ZHAO, SANAT KUMAR, Chemical Engineering, Columbia University — An interfacial polymer layer, or bound layer, has long been of interest in polymer nanocomposites (PNCs) since the divergent properties of the bound layer as compared to the bulk can have very important effects on PNCs properties. We study a system comprised of silica nanoparticles (NPs) in poly-2-vinylpyridine (P2VP) prepared by the solvent casting method. First, we determine by TGA the bound layer thickness δ in PNCs and show that *i)* δ decreases as NP radius decreases due to a decrease of polymer adsorbed amount and *ii)* δscales as $N^{1/2}$, where N is the chain length, independent of NP size. This result qualitatively follows the theoretical prediction in term of loops distribution developed by Guiselin et al. for a flat surface. Here we note that the bound layer thickness is obtained by assuming that the polymer chains have a density corresponding to a dense melt – this is clearly not a well-founded argument, and hence we measure a more realistic extent of the bound layer by using Dynamic Light Scattering in solution. Then, we investigate the influence of the solvent used to prepare the PNCs (in our case methylethylketone (MEK) or pyridine) on the bound layer and the final silica dispersion in PNCs. We show that pyridine prevents the P2VP adsorption leading to poor silica dispersion in the final PNCs while in MEK the good dispersion is related to the formation of a bound layer.

4:30PM C32.00011 Non-isothermal melt crystallization behavior of Poly(ethylene terephthalate)/graphene nanocomposites , SHIGERU AOYAMA, YONG TAE PARK, TOSHIAKI OUGIZAWA, CHRISTOPHER MACOSKO, Dept. Chemical Engineering & Materials Science, University of Minnesota — Poly(ethylene terephthalate)(PET)/graphene nanocomposites were prepared by melt mixing with a goal of reduced gas permeability. With 2 wt% of few layered graphene, PET/graphene composite films show more than 70% decrease in N_2 gas permeation. Their non-isothermal crystallization were also investigated by differential scanning calorimetory (DSC). Crystallization temperature, Tc, of PET/graphene nanocomposites was more than 8 °C higher than neat PET and the increment increased along with the concentration of graphene. This suggests that the nucleation effect of graphene enhanced with the increase in concentration of graphene. On the other hand, PET/graphene nanocomposites show shorter half crystallization time, $t_{1/2}$, than neat PET at lower concentrations, but $t_{1/2}$ increased along with concentration of graphene. From Raman spectroscopy, it was shown that PET chains in nanocomposites are strongly confined in the presence of an excess of graphene. Restricted mobility of PET chains slowed crystallization.

4:42PM C32.00012 Annealing polymer nanocomposite fibers and films with photothermal heating: effects on overall crystallinity and resultant mechanical properties[1] , VIDYA VISWANATH, SOMSUBHRA MAITY, JASON BOCHINSKI, LAURA CLARKE, RUSSELL GORGA, North Carolina State University — Metal nanoparticles embedded within polymeric systems can be made to act as localized heat sources thereby aiding in-situ polymer processing. This is made possible by the surface plasmon resonance (SPR) mediated photothermal effect of gold nanoparticles, wherein incident light absorbed by the nanoparticle generates a non-equilibrium electron distribution which subsequently transfers this energy into the surrounding medium, resulting in a temperature increase in the immediate region around the particle. The current research demonstrates this effect in polymer nanocomposite systems, electrospun nanofiber mats and thin films, which have been annealed at temperatures above the glass transition and below melting. A non-contact temperature measurement technique utilizing embedded fluorophores has been used to monitor the average temperature within samples. The effect of annealing methods (conventional and plasmonic), annealing conditions (temperature and duration) and cooling mechanisms on the morphology, crystallinity, and mechanical properties of polymeric nanocomposite systems will be discussed. The specificity of plasmonic heating coupled with the inside-outside approach of annealing presents a unique tool to thermally process polymers.

[1]NSF grant MPM 1069108.

4:54PM C32.00013 DSC study of the isothermal crystallization of iPP-CNF nanocomposites[1] , DORINA M. CHIPARA, MIRCEA CHIPARA, The University of Texas Pan American — Nanocomposite materials have been obtained by dispersing vapor grown carbon nanofibers (VGCNFs) with diameters ranging between 60 and 100 nm and lengths between 30,000 and 100,000 nm supplied by Pyrograf Products, Inc (PR-24AG) within a polymer matrix - isotactic polypropylene (iPP) - type Marlex HLN-120-01 with density 0.906 g/cm^3 and melt flow rate at 230 ^{o}C of 12 g/10 min, supplied by Philips Sumika Polypropylene Company. VGCNFs have been purified and disentangled by reflux in dichloromethane and deionized water followed by vacuum filtering (for 24 h) and drying at 110 ^{o}C for 24h. The nanocomposites were obtained by melt mixing at 180 ^{o}C for 9 minutes with a speed of 65 rpm followed by an additional mixing at 90 rpm for 5 minutes, using a HAAKE Rheomix, Nanocomposites loaded with various amounts of VGCNFs (0%, 1%, 2.5%, 5%, 7.5%, 10%, 15%, and 20% wt.) have been prepared and investigated by TA DSC Q-500. Isothermal crystallization was investigated in detail and analyzed by using an expression derived from the Avrami equation. The effect of the filler on the isothermal crystallization of iPP is discussed in detail. The research is focused on the effect of VGCNF on the degree of crystallization of iPP, crystallization rate, and dimensionality of the crystallization process.

5:06PM C32.00014 The Impact of Fullerenes on the Ordering of Polyacrylonitrile in Nanocomposites[1] , ADAM IMEL, MARK DADMUN, Department of Chemistry University of Tennessee — The presence of nanoparticles can impact the crystallization and ordering of polymer chains in a nanocomposite. We have found that certain fabrication conditions of polyacrylonitrile (PAN) and fullerenes, as well as PAN and SWNTs, produce a SAXS peak. This SAXS peak is similar to a microphase separation peak and indicates a self-assembly of the nanocomposite on a length scale of $\sim$ 150 Å. In order to identify the origin of this peak, we have completed dynamic light scattering, viscosity, small angle x-ray scattering and wide-angle x-ray scattering experiments to characterize the dispersion of C60 in solution and in the final solid nanocomposite. These results support a completely miscible solution. The interpretation of the SAXS & WAXS results suggest that the addition of C60 directs the crystallization of PAN in the final nanocomposite by dramatically decreasing the amount of crystallinity while also affecting the packing structure and limiting the size of the PAN crystals.

5:18PM C32.00015 Polymer Lamellar Crystals Containing Precise Half-Folds Confined by Nano-Particles of Giant Molecular Shape Amphiphiles , XUEHUI DONG, None — Chain-folded polymer lamellar crystals with precise half-folds were first time experimentally observed in two specifically designed giant molecular shape amphiphiles. These molecules were synthesized via Click Chemistry to construct a nano-particle such as polyhedral oligomeric silsesquioxane (POSS) or [60]fullerene (C_{60}) tethered a poly(ethylene oxide) (PEO) chain as a tail. When these PEO tails crystallized, both integral folded crystals and crystals with the half-folds were identified experimentally. This is due to the fact that during the PEO tail crystallization, the nano-particles at ends of PEO chains build up double layered structures to impose the PEO chains to create specific number of stems in their crystals which must balance the cross-sections of the nano-particles and the stems.

2:30PM C33.00001 Interface Charge Transport in Organic Transistors as Investigated by Field-Induced Electron Spin Resonance , TATSUO HASEGAWA, AIST — Most of high-performance organic thin-film transistors (OTFTs) as recently developed is attainable with non-doped, single-component π-conjugated materials that exhibit high layer crystallinity both for small-molecules and polymers. The layer crystallinity is quite suitable to compose channel transport layers of the OTFTs, although the main origin to hinder the charge transport or the intrinsic carrier mobility is still controversial; intra- or intermolecular electron-phonon coupling, polarization effects by the gate-dielectrics, or thermal or extrinsic disorder effects. Here we discuss the interface charge transport in the OTFTs, as investigated by field-induced electron spin resonance (FESR) technique that probes 1/2 spin of carriers induced by gate voltage. It is shown that the FESR technique is extremely useful especially for OTFTs, because of the fairly small spin-orbit interactions in organic materials as well as of the high layer crystallinity and the anisotropy. The following important aspects of the interface charge transport are presented and discussed: (1) Carrier motion in OTFTs can be understood in terms of the multiple trap-and-release (MTR) transport. The analyses of the motional narrowing effects allow us to estimate the average trap residence time that reaches about 1 ns [1]. (2) Carriers are frozen at the respective trap sites at low temperature. The low-temperature spectral analyses allow us to obtain the distribution of trapped carriers over their degree of localization [2, 3]. (3) We also developed a unique technique to investigate the intra- and inter-domain transport in polycrystalline OTFTs by using anisotropic FESR measurements. The method allows us to evaluate the potential barrier height at the domain boundaries within the films [4].

3:06PM C33.00002 Gold contacts for rubrene SC–FETs: the older, the better , TINO ZIMMERLING, BERTRAM BATLOGG, ETH Zurich — Excellent charge injection, device stability, and high reproducibility in the device fabrication are key to investigate intrinsic properties of organic semiconductors in e.g. diodes and field-effect transistors (FETs). In this systematic study we show that these requirements can be met by properly conditioning the gold electrodes in a rubrene flip crystal FET — a setup which is frequently used to explore fundamental organic electronic physics. Gold electrodes have been evaporated under HV conditions on Cytop as gate insulator. The electrodes had been exposed to air for 15 min to 1000 min before rubrene crystals have been laminated. We evaluated the efficiency of charge injection by calculating the contact resistance at the gold–rubrene interface. We observe a systematic decrease of the contact resistance by factors of up to 10^3 and improved device stability in terms of contact resistance and mobility after long-term air exposure. From these findings we deduce a simple recipe to fabricate non-contact-limited FETs employing rubrene crystals and gold electrodes. These observations in a typical laboratory environment are in line with the view that charge injection is not simply determined by the ideal metal workfunctions and the HOMO/LUMO levels measured under UHV conditions.

3:18PM C33.00003 Indium Free Transparent Electrodes with a Tungsten Oxide Hole Blocking Layer for Organic Photovoltaic Devices , ROY MURRAY, University of Delaware, PATRICK REINECKE, Albert-Ludwigs University, Freiburg, Germany and Fraunhofer Insitute for Solar Energy, NOPPORN RUJISAMPHAN, University of Delaware, ULI WÜRFEL, Albert-Ludwigs University, Freiburg, Germany and Fraunhofer Insitute for Solar Energy, S. ISMAT SHAH, University of Delaware — Indium Tin Oxide (ITO), the standard transparent electrode used in organic photovoltaic (OPV) devices, is expensive and cannot be deposited well on flexible plastic substrates due to its high temperature post deposition annealing. As a replacement for ITO, we used a sputtered Al-ZnO/Ag/WOx film as the transparent electrode. The work function of this electrode was found using a Kelvin Probe to be between 5 and 5.4 eV, depending on thickness. We tested several OPV materials of varying LUMO and HOMO levels on the WOx layer and found that a difference of greater than 0.2 eV between the HOMO of the donor and the conduction band of the WOx resulted in poor device performance. We further investigated the alteration of the WOx work function through doping and altering the thickness. Device analysis and cross sectional transmission electron microscope (TEM) pictures using a focused ion beam were performed.

3:30PM C33.00004 Poly(3-hexylthiophene) Band Alignment With SiO2 Determined By Internal Photoemission , WEI LI, National Institute of Standards and Technology, Physical Measurement Laboratory, Gaithersburg, Maryland, USA, XUELEI LIANG, Key Laboratory for Physics and Chemistry of Nano Devices, Peking University, Beijing, China, JAMES BASHAM, KUN XU, QIN ZHANG, OLEG KIRILLOV, RUSEN YAN, CURT RICHTER, National Institute of Standards and Technology, Physical Measurement Laboratory, Gaithersburg, Maryland, USA, THOMAS JACKSON, Pennsylvania State University, University Park, PA 16801 USA, N.V. NGUYEN, DAVID GUNDLACH, National Institute of Standards and Technology, Physical Measurement Laboratory, Gaithersburg, Maryland, USA — We report band alignment for the widely studied organic semiconductor, Poly(3-hexylthiophene) (P3HT), by using internal photoemission (IPE). P3HT solution was spin coated onto 280 nm thick SiO_2 on heavily doped P-type silicon. A 10 nm thick aluminum (Al) electrode with adjoining 70 nm thick Al contact pad were deposited onto the P3HT film through aligned shadow masks. Photocurrent in the IPE measurement was generated using a monochromator with photon energy ranging from 1.5eV to 6.0eV (0.05 eV steps) and with a DC voltage which ranged from 20V to -20V (-2V steps) applied between the silicon backside and the thick Al contact. Both positive photocurrent and negative photocurrent were observed. For the IPE measurement, the yield (Y) is defined as the ratio of the carriers contributing to the photocurrent to the incident photon flux, and the threshold at each applied voltage is obtained by extrapolating $Y^{1/3}(h\nu)$ to zero. The barrier height is determined from Schottky plots extrapolated to zero field. By using this established method we extract a barrier height of 4.2 eV $\pm$ 0.1 eV for the Si:SiO2 interface and 4.0 eV $\pm$ 0.1 eV for the P3HT:SiO_2 interface, respectively.

3:42PM C33.00005 Electron Injection to Control Self-Assembly and Disassembly of Phenylacetylene on Gold[1] , ARTHUR P. BADDORF, QING LI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CHENGBO HAN, J. BERNHOLC, Department of Physics, North Carolina State University, HUMBERTO TERRONES, BOBBY SUMPTER, MIGUEL FUENTES-CABRERA, JIEYU YI, ZHENG GAI, PETER MAKSYMOVYCH, MINGHU PAN, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — The power of two-dimensional organic molecular systems for applications including electronics, functionalization and nanolithography is enabled by our ability to produce structures through self-assembly on a surface. Unfortunately, relying on thermal fluctuations to drive the surface attachment reactions has limited self-assembled molecules (SAMs) to little beyond alkanethiols on gold. We demonstrate a seminal example of non-thermal control over molecular self-assembly, where hot-electron injection rather than thermal fluctuations transform a disordered layer of weakly bonded hydrocarbon molecules into an ordered, dense monolayer. The process is reversible, in that injection of holes reverts to a disordered state. Since electron and hole injection is accomplished with a STM, unprecedented local control over ordered and disordered domains is achieved. STM imaging and correlated density functional calculations reveal that ordered domains consist of molecules vertically aligned and more strongly attached to the gold substrate through the acetylene tail, while disordered domains contain weakly bound molecules lying flat.

[1]Research was conducted at the CNMS, sponsored by the Division of Scientific User Facilities, U.S. Department of Energy.

3:54PM C33.00006 Scanning Tunneling Microscopy and Spectroscopy of Thin Films of the Organic Semiconductor Picene , SIMON KELLY, GEOFFREY ROJAS, PETRO MAKSYMOVYCH, Oak Ridge National Laboratory, CNMS COLLABORATION — Characterizing organic semiconductors at the single molecule scale has greatly enhanced our understanding of intermolecular interactions, revealing new approaches to controlling film structure, while probing the electronic properties of organic interfaces. Pentacene has long been a model system for such studies. Here we study monolayer and bilayer films of picene, a structural isomer of pentacene. We grow these films on Ag(111) by thermal evaporation in UHV and measure them in-situ using a low-temperature STM at $\sim$ 77 K. Topographic STM measurements were used to establish the film structure. Much like pentacene, picene bonds with its molecular plane parallel to the surface, but unlike pentacene, picene forms dimers. Moreover, the work-function shift amounts to almost 1 eV (up to 2x the value for pentacene), suggesting that the molecule-surface distance is closer in this case. At the same time, the splitting of the LUMO, LUMO+1, and LUMO+2 molecular orbitals is somewhat larger than even semiempirically calculated values for the gas-phase. These measurements will be compared to first principles calculations made with the HSE functional to understand changes to the electronic structure with adsorption and the role of van-der-Waals interactions between flat-lying picene molecules.

4:06PM C33.00007 ABSTRACT WITHDRAWN –

4:18PM C33.00008 Computational Study of Phenylacetylene Self-Assembly on Au(111) Surface[1] , CHENGBO HAN, WENCHANG LU, JERRY BERNHOLC, NCSU, QING LI, MIGUEL FUENTES-CABRERA, HUMBERTO TERRONES, BOBBY SUMPTER, JIEYU YI, ZHENG GAI, ARTHUR BADDORF, PETRO MAKSYMOVYCH, MINGHU PAN, CNMS, ORNL, CENTER OF NANOPHASE MATERIALS SCIENCES, ORNL TEAM, NC STATE UNIVERSITY TEAM — The direct control over Phenyl-Acetylene (PA) self-assembly/disassembly on gold, achieved by carrier injection through an STM tip, is unprecedented. We discuss theoretical interpretation of PA structures observed on Au(111) by direct STM imaging in the preceding talk. We have examined 20 different adsorption geometries through first-principles calculations, simulated their STM images and compared them to the experimentally observed patterns. While weakly adsorbed PA prefers flat orientation on Au(111), the self-assembly leads to significant rearrangement of its adsorption structure. We obtain excellent agreement with the experimental data for a densely packed, ordered monolayer of vertically aligned but tilted styrene-derivative adsorption geometry, in which the acetylene tail is directly bonded to the surface. All the major features of the experimental STM image are reproduced by calculations, leading to unambiguous determination of the self-assembled structure [1]. We will also discuss the changes in adsorption energetics and molecular level alignment induced by the self-assembly process.

4:30PM C33.00009 Electronic Structure of CoPc Adsorbed onto Ag(100): Evidence for Molecule-Substrate Interaction Mediated by Co-3d Orbitals , ERIC SALOMON, Aix-Marseille University, France, PATRICK AMSALEM, Humboldt University, Berlin, Germany, NOA MARÓM, The University of Texas at Austin, MARTIN VONDRACEK , Institute of Physics AS CR, Czech Republic, LEEOR KRONIK, Weizmann Institute of Science, Israel, NORBERT KOCH, Humboldt University, Berlin, Germany, THIERRY ANGOT, Aix-Marseille University, France — The electronic structure of cobalt-phthalocyanine (CoPc) molecules adsorbed on Ag(100) is investigated by photoemission spectroscopy. The results are compared to first principles electronic structure calculations, based on many-body perturbation theory in the GW approximation. The photoemission data, obtained from both multilayer and monolayer films of CoPc, showthat charge-transfer occurs between the first molecular layer and the metal surface. Varying the photon energy, to tune the photoionization cross sections, reveals that the charge-transfer related interface states mainly involve the Co-3d atomic orbitals of the Co central atom. GW calculations for the neutral CoPc molecule and its anion compare well with the experimental observations for a multilayer and a monolayer CoPc fillm, respectively. They confirm the major role played by the Co atom in the charge transfer process and elucidate the complex energy rearrangement of the molecular electronic levels upon adsorption on the metal.

4:42PM C33.00010 The role of micro-shorts and electrode-film interface in the electrical transport of ultra-thin metallophthalocyanine capacitive devices[1] , CARLOS MONTON, ILYA VALMIANSKI, IVAN K. SCHULLER, Department of Physics and Astronomy, University of California San Diego, 9500 Gilman Dr., San Diego, La Jolla, CA 92093, U.S.A — The transport properties of metallophthalocyanine thin films are of much basic interest and are important ingredients in many technological applications. Ohmic conductance Co-phthalocyanine (CoPc) of thin film (15 nm to 90 nm) capacitive devices has been investigated in the 40K to 300 K temperature range. For Pd and V electrodes, the electrode-film (E-F) interface and metallic micro-shorts contribute substantially to the conductance with decrease CoPc layer thickness. A quantitative model which describes the E-F interface, CoPc roughness, micro-shorts, and the exponential temperature and thickness dependence of conductance was developed. Parameters obtained from this model are in good, quantitative agreement with independent measurements. The model predicts a 15-20 nm lower limit for capacitive device thickness, below which the conduction is mainly controlled by shorts. In this regime, small changes in mean CoPc thickness result in drastic variation in device conductance.

4:54PM C33.00011 ABSTRACT WITHDRAWN –

5:06PM C33.00012 Phase separation-driven stratification in conventional and inverted P3HT:PCBM organic solar cells[1] , ELENI PAVLOPOULOU, GUILLAUME FLEURY, DARGIE DERIBEW, LCPO, University of Bordeaux, France, FABRICE COUSIN, Laboratoire Léon Brillouin, CEA-CNRS, France, MARK GEOGHEGAN, University of Sheffield, UK, GEORGES HADZIIOANNOU, LCPO, University of Bordeaux, France — We have used neutron reflectivity to investigate the stratification of poly(3-hexylthiophene) (P3HT) and phenyl-C_{61}-butyric acid methyl ester (PCBM) blend films. Films were spun-cast on poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) and titanium oxide (TiOx) layers to mimic the procedures followed for the fabrication of conventional and inverted organic photovoltaics respectively. A 60% and 75% PCBM enrichment of the active layer at the interface with PEDOT:PSS and TiOx respectively has been revealed, as well as a PCBM depletion at the free surface of the film which is driven by the lower surface energy of P3HT. PCBM segregation close to the substrate is further enhanced by annealing. In case of the films cast on PEDOT:PSS, this stratification could be detrimental for conventional solar cell performance, since the electron-acceptor material enriches the interface with the hole-collecting electrode. The agglomeration of PCBM at the TiOx interface could, however, be favorable for an enhanced charge collection, thus improving device performance.

5:18PM C33.00013 Atomic and Electronic Structure of the P3HT/PCBM Interface From First-Principle Calculations[1] , LONGHUA LI, OLEG KONTSEVOI, ARTHUR J. FREEMAN, Northwestern Universtiy — Fundamental research on donor/acceptor (D/A) interfaces of organic photovoltaics (OPV) have drawn immense interest because of their crucial roles in charge separation (CS), charge transfer (CT) and charge recombination (CR). The blend system consisting of regioregular poly(3-hexylthiophene) (rr-P3HT) and fullerene derivative [6,6]-phenyl C_{61} butyric acid methyl ester (PCBM) is a widely investigated binary system. Despite significant efforts that have been done to optimize the OPV, such as the D/A ratio, detailed information on their structure, interfaces, and morphology are far from complete. Additionally, fewer investigations have focused on the elementary charge transfer processes. In this work, such a hetero-interface was carried out by annealing simulation; and then interfacial electronic structure and charge transfer were studied by DFT calculations. The process of PCBM assembly on the P3HT surface were shown and the carrier mobilities could be tuned by PCBM orientations.Our calculations provide an important understanding on the assembly of PCBM and charge transfer at the binary interface.

Session C34 DPOLY: Thin Films of Block Copolymers and Hybrid Materials: Mechanics and Dynamics 342 - Alamgir Karim, University of Akron

2:30PM C34.00001 Structural response of a pre-aligned cylindrical block copolymer to uniaxial extensional flow , ERICA MCCREADY, WESLEY BURGHARDT, Northwestern University — In situ small angle x-ray scattering (SAXS) is used to probe structural changes in a cylindrically ordered triblock copolymer melt during uniaxial extensional flow. The sample is a styrene-ethylene butylene-styrene triblock copolymer melt. Sheets of macroscopically oriented polymer were produced using a lubricated planar squeezing flow die, from which sample strips were cut. Uniaxial extensional flow was imposed in the melt state using an SER extensional flow fixture housed in a custom built convection oven that allows x-ray access, to facilitate SAXS measurements of microdomain re-orientation and deformation during stretching and subsequent relaxation. Individual sample strips were cut from the molded sheet to facilitate measurements in which the stretching was imposed either parallel or perpendicular to the pre-alignment axis. Offline measurements of transient extensional rheology were also conducted using the SER fixture in a conventional rotational rheometer, using similar samples in order to explore connections between, and impact of initial orientation state one, both structural and mechanical responses.

2:42PM C34.00002 Imaging surface mechanical properties of complex polymer thin films using Intermodulation Atomic Force microscopy , DANIEL FORCHHEIMER, DANIEL PLATZ, DAVID B. HAVILAND, Royal Institute of Technology (KTH), Stockholm, Sweden, ERIK A. THOLÉN, Intermodulation Products AB, Solna, Sweden — The atomic force microscope (AFM) has been the method of choice to measure surface topography of thin films on the sub-micron scale. In addition to topography, dynamic AFM, where the cantilever is oscillated at its resonance frequency, gives a qualitative image of material heterogeneity by recording the phase lag of the oscillation. As new materials become increasingly more complex, containing multiple components and phases, there is an increased need for more sensitive and also more quantitative characterization polymer surfaces at the nanometer scale. We have developed Intermodulation AFM in which the cantilever is excited at two frequencies close to resonance. By measuring the intermodulation products, or mixing products, of the drive frequencies more information regarding the tip-surface interaction is revealed, providing better material contrast and allowing quantitative reconstruction of the tip-surface force curve. We have applied this method to the study of thin films of polymer blends and block copolymers in which it was possible to quantify material stiffness of the different phases of the material and relate those to quantitative measurements of the pure polymer components.

2:54PM C34.00003 Morphology and Surface Energy of a Si Containing Semifluorinated Diblock Copolymer Thin Films.[1] , UMESH SHRESTHA, Clemson University, STEPHEN CLARSON, University of Cincinnati, DVORA PERAHIA, Clemson University — The structure and composition of an interface influence stability, adhesiveness and response to external stimuli of thin polymeric films. Incorporation of fluorine affects interfacial energy as well as thermal and chemical stability of the layers. The incompatibility between the fluorinated and non-fluorinated blocks induces segregation that leads to long range correlations where the tendency of the fluorine to migrate to interfaces impacts the surface tension of the films. Concurrently Si in a polymeric backbone enhances the flexibility of polymeric chains. Our previous studies of poly trifluoro propyl methyl siloxane-polystyrene thin films with SiF fraction 0.03-0.5 as a function of temperature have shown that the SiF block drives layering parallel to the surface of the diblock. Here in we report the structure and interfacial energies of SiF-PS in the plane of the films, as a function of the volume fraction of the SiF block obtained from Atomic Force microscopy and contact angle measurement studies.

3:06PM C34.00004 Elastic Properties of Bilayer Membranes Self-Assembled from Diblock Copolymers , KYLE PASTOR, Department of Physics and Astronomy, McMaster University, Hamilton, Canada, JIANFENG LI, Department of Macromolecular Science, Fudan University, Shanghai 200433 China, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University, Hamilton, Canada — The elastic properties of bilayer membranes are studied using self-consistent field theory (SCFT). The membranes are formed in a blend of AB diblock copolymers and C-homopolymers which act as the solvent. The free energy of a membrane is determined from the SCFT solutions. Fitting the membrane free energy to a continuum elastic model allows the determination of the bending and Gaussian modulus of the bilayers. More importantly, a comparison of the SCFT free energy and the Helfrich model can be used to determine the limit of the linear elastic model. A threshold curvature, at which the linear elasticity theory breaks down, is used to determine the validity region of the Helfrich model in the parameter space of the system.

3:18PM C34.00005 Exploring the atom-resolution properties of peptoid nanosheets , RANJAN MANNIGE, RONALD ZUCKERMANN, STEPHEN WHITELAM, Molecular Foundry, Lawrence Berkeley National Laboratory, STEVE WHITELAM TEAM[1], RONALD ZUCKERMANN COLLABORATION[2] — Peptoids are artificial positional isomers of peptides, where the sidechains are attached to the backbone nitrogen in stead of the alpha carbon. Recently, an amphiphilic peptoid was found to form bilayers (nano-sheets) that expand in area to the mesoscopic level but which display uniform thickness of only between 2 to 3 nanometers. While progress in the chemical synthesis of these sheets have witnessed leaps, an atomistic understanding of peptoid nanosheets is lacking. We report recent developments in the atomistic simulation of assembled peptoid nanosheet candidates which resulted in a configurational energy landscape where only specific arrangements of peptoids are energetically feasible. Additionally, we find that while the charged sidechains situated on the exterior of the bilayer describe the general arrangement of the sheet, the exact positions of each peptoid appears to be dominated primarily by the hydrophobic residues that interact in the interior of the bilayer. These results provide a novel picture of the atomistic features of peptoid nanosheets, which serves as a useful platform for the further and rational development of novel peptoid nanosheets.

3:30PM C34.00006 3D TEM Tomography of Bilayer Diblock Copolymer Thin Films , KEVIN GOTRIK, MIT, THOMAS LAM, NIST, ADAM HANNON, MIT, J. ALEXANDER LIDDLE, NIST, CAROLINE ROSS, MIT — Being able to control the orientation and direction of block copolymer microdomains is of interest for lithographic applications due to the ability to form sub-10 nm feature sizes. Bilayer diblock copolymer films (42 nm as-cast film thickness) of cylinder forming poly(styrene-b-dimethylsiloxane) (PS-PDMS, 45 kg/mol, Flory-Huggins interaction parameter(χ) =0.224 at room temperature) can be precisely controlled by templating arrays of PS functionalized post barriers (15 nm diameter) that are periodically spaced on the order of 30-60 nm. The resulting morphologies are 3D in nature due the ability of the posts to decouple the orientation and direction of the two different layers of cylinders. Self-consistent field theory predicts a range of possible bilayer structures that are similar in energetics and that would appear similar when viewed from the top down as is commonly done with SEM after selectively etching the PS with an oxygen plasma (50W CF_4). This destructive method of imaging therefore limits the ability to compare between different bilayer morphologies that may be forming. Here we show how 3D TEM tomography can be used as a non-destructive way to image the cylindrical microdomains to determine the block copolymer morphology before etching.

3:42PM C34.00007 High Resolution Imaging of Polymers Using Stochastic Optical Reconstruction Microscopy (STORM) , M.W. GRAMLICH, J. BAE, R. HAYWARD, J.L. ROSS, University of Massachusettes - Amherst — Recent super-resolution fluorescence imaging techniques represent attractive new methods for structural characterization of polymeric systems. STORM is a technique developed over the last decade to image structure and dynamics in biological systems. The high spatial resolution approaches that of other well-established techniques, such as atomic force microscopy (AFM) or scanning electron microscopy, but with all the advantages of a far-field optical technique. We have adapted STORM imaging techniques to polymeric materials, specifically using thin film blends of polystyrene (PS) and poly(methyl methacrylate) (PMMA) as a model system. We labeled PMMA with Alexa-647 fluorescent dye, and combined 10wt% label to un-labeled PMMA, then prepared 50:50 by weight blends with PS. We find the lateral PMMA domain size increases with film thickness. Furthermore, we show that the structure and size of the domains is equivalent to results from AFM. Funding is acknowledged from NSF MRI grant#DBI-0923318 to Ross and Wadsworth, "Development of FPALM-STORM for Live Cell Single Molecule Microscopy"; NSF MRSEC grant #DMR-0820506 to UMass. We would like to acknowledge Rachel Letteri, Brent Hammer, Todd Emrick, Weiyin Gu, and Tom Russell for help with material preparation.

3:54PM C34.00008 Nano-spectroscopic vibrational chemical imaging of block-copolymer phase behavior , BENJAMIN POLLARD, MARKUS B. RASCHKE, University of Colorado Boulder — Block copolymers phase-separate to form a wide range of different types of structures on mesoscopic length scales, controlled by relative chain lengths, solvent, and substrate interactions. However, the investigation of their complex phase behavior has remained difficult using traditional scanning-probe techniques due to a lack of the desired nanoscale chemical specificity. Here, we demonstrate the combination of scattering Scanning Near-field Optical Microscopy (*s*-SNOM) with ultrahigh sensitive infrared vibrational spectroscopy to provide compositional mapping on the sub-domain level. Probing the carbonyl resonance in thin films of poly(methylmethacrylate)-b-polystyrene (PMMA:PS) diblock copolymers, we identify distinct local PMMA density distributions and surface terminations comparing micellar and lamellar structures. With this technique we demonstrate an infrared spectroscopic sensitivity as high as a few 100 monomers and 10 nm spatial resolution. We discuss the extension to related soft-matter systems, including self-assembled monolayers and biomaterials.

4:06PM C34.00009 Tuning the lateral mobility of thin block copolymer films[1] , HARRY BERMUDEZ, ANDREAS KOUROUKLIS, University of Massachusetts — Polymer mobility in confined environments is of both theoretical and practical interest. The controlled formation and characterization of systems where such effects can be studied remain active areas of investigation. In this work, we created ultrathin ($<$ 50 nm) supported films of amphiphilic polybutylene-poly(ethylene) oxide diblock copolymers, through Langmuir-Blodgett and Langmuir-Schaefer techniques. To adjust the lateral mobility of these ultrathin films, short polyisobutylene homopolymer was introduced during the film assembly process. Preliminary fluorescence recovery after photobleaching (FRAP) results show that the lateral mobility of the block copolymers is proportional to the logarithm of homopolymer concentration. The mobility can be varied by up to a factor of 8 with as little as 1 mol% of homopolymer. The role of the added homopolymer on the block copolymer lateral mobility is likely to be related with several features such as chain entanglements, interfacial constraints, and interlayer friction. By varying the concentration and the molecular weight of the homopolymer introduced into the films, we attempt to explain the underlying physical mechanisms that are responsible for changes in lateral mobility.

[1]National Science Foundation

4:18PM C34.00010 Autophobic dewetting of symmetric diblock copolymer films on ordered lamellae , MARK ILTON, Department of Physics and Astronomy, McMaster University, Hamilton, ON, Canada, PAWEL STASIAK, MARK W. MATSEN, School of Mathematical and Physical Sciences, University of Reading, Whiteknights, Reading, UK, KARI DALNOKI-VERESS, Department of Physics and Astronomy, McMaster University, Hamilton, ON, Canada — Autophobic dewetting is the process in which a material retracts from a substrate of the same material. This has been observed for homopolymer melts on brush layers as well as in diblock copolymer systems. In the case of diblock copolymer films, autophobic dewetting can arise above the bulk order-disorder transition temperature due to a gradient of segregation strength induced by the film interfaces. We have measured the contact angle of autophobically dewetting droplets of symmetric polystyrene-b-poly(2-vinyl pyridine) as a function of temperature and the number of ordered lamellae that form the substrate layer. The contact angle decreases monotonically with both temperature and the number ordered lamellae, which can be understood as a dependence on the degree of order at the substrate interface. We compare our experimental results to a self-consitent field theory calculation which includes the decaying order away from the interfaces.

4:30PM C34.00011 Experimental diffusion measurements of entangled rod-coil block copolymers , MUZHOU WANG, KSENIA TIMACHOVA, ALFREDO ALEXANDER-KATZ, BRADLEY OLSEN, Massachusetts Institute of Technology — A fundamental theory for the dynamics of rod-coil block copolymers is important for understanding diffusion, mechanics, and self-assembly kinetics in functional nanostructured materials for organic electronics and biomaterials. Recently our group has proposed a reptation theory for the diffusion of entangled rod-coil block copolymers, showing the slower dynamics of rod-coils is due to the mismatch between the curvature of the rod and coil blocks. Here we present experimental tracer diffusion measurements of model rod-coil diblock and coil-rod-coil triblock copolymers that support this theory. The model systems are composed of poly(ethylene oxide) coils and polyalanine α-helical rods synthesized by bacterial expression and bioconjugation, and tracer diffusion in entangled solutions is measured by forced Rayleigh scattering. The experiments support both the activated reptation and arm retraction mechanism for the small and large rod regimes that were previously presented in our theory. Comparison of both simulation and experiments between diblock and triblock copolymers suggests that the diffusion mechanisms are independent of the different symmetry and molecular architecture of the molecules.

4:42PM C34.00012 Dynamic Processes in Diblock Copolymer Micelles , MEGAN ROBERTSON, AVANTIKA SINGH, University of Houston — Diblock copolymers, which form micelle structures in selective solvents, offer advantages of robustness and tunability of micelle characteristics as compared to small molecule surfactants. Diblock copolymer micelles in water have been a subject of great interest in drug delivery applications based on their high loading capacity and targeted drug delivery. The aim of this work is to understand the dynamic processes which underlie the self-assembly of diblock copolymer micelle systems which have a semi-crystalline core. Due to the large size of the molecules, the self-assembly of block copolymer micelles occurs on significantly longer time scales than small molecule analogues. The present work focuses on amphiphilic diblock copolymers containing blocks of poly(ethylene oxide) (a hydrophilic polymer) and polycaprolactone (a hydrophobic, semi-crystalline polymer), which spontaneously self-assemble into spherical micelles in water. A variety of experimental techniques are used to probe the kinetic processes relevant to micelle self-assembly, including time-resolved neutron scattering, dynamic light scattering, pulsed field gradient nuclear magnetic resonance, and fluorescence resonance energy transfer experiments.

4:54PM C34.00013 Molecular exchange in block copolymer micelles: when corona chains overlap[1] , JIE LU, TIMOTHY LODGE, FRANK BATES, University of Minnesota, Twin Cities, SOOHYUNG CHOI, Hongik University, Seoul, South Korea — The chain exchange kinetics of poly(styrene-b-ethylenepropylene) (PS-PEP) diblock copolymer micelles in squalane ($C_{30}H_{62}$) was investigated using time-resolved small angle neutron scattering (TR-SANS). The solvent is a mixture of h-squalane and d-squalane that contrast-matches a mixed 50/50 h/d PS micelle core. As isotope labeled chains exchange, the core contrast decreases, leading to a reduction in scattering intensity. This strategy therefore allows direct probing of the chain exchange rate. Separate copolymer micellar solutions containing either deuterium labeled (dPS) or normal (hPS) poly(styrene) core blocks were prepared and mixed at room temperature, below the core glass transition temperature. The samples were heated to several temperatures (around 100 °C) and monitored by TR-SANS every 5 min. As polymer concentration was increased from 1% to 15% by volume, we observed a significant slowing down of chain exchange rate. Similar retarded kinetics was found when part of the solvent in the 1% solution was replaced by homopolymer PEP (comparable size as corona block). Furthermore, if all the solvent is replaced with PEP, no exchange was detected for up to 3hr at 200 °C. These results will be discussed in terms of a molecular model for chain exchange

5:06PM C34.00014 Direct solvent induced microphase separation, ordering and nano-particles infusion of block copolymer thin films[1] , ARVIND MODI, The University of Akron, ASHUTOSH SHARMA, Indian Institute of Technology Kanpur, ALAMGIR KARIM, The University of Akron — Kinetics of block copolymer (BCP) microphase separation by thermal annealing is often a challenge to low-cost and faster fabrication of devices because of the slow ordering. Towards the objective of rapid processing and accessing desired nanostructures, we are developing methods that enable a high degree of mobility of BCP phases while maintaining phase separation conditions via control of effective interaction parameter between the blocks in BCP thin films. We study the self-assembly of PS-P2VP thin films in various solvent mixtures. While non-solvent prevents dissolution of film into the bulk solution, the good solvent penetrates the film and makes polymer chains mobile. As a result of controlled swelling and mobility of BCP blocks, solvent annealing of pre-cast BCP thin films in liquid mixture of good solvent and non-solvent is a promising method for rapid patterning of nanostructures. Interestingly, we demonstrate simultaneous BCP microphase separation and infusion of gold nano-particles into selective phase offering a wide range of application from plasmonics to nanoelectronics.

5:18PM C34.00015 Synthesis of Well-Defined Miktoarm Star Copolymer composed of Poly(3-hexylthiophene) and Poly(methyl methacrylate) via combining anionic polymerization and click reaction , JICHEOL PARK, HONG CHUL MOON, JIN KON KIM, Pohang University of Science and Technology — We synthesized well-defined miktoarm star copolymer composed of regioregular poly(3-hexylthiophene) and poly(methyl methacrylate) ((P3HT)$_2$-*b*-PMMA) by combining anionic polymerization and click reaction. First, we synthesized PMMA terminated with 1,3,5-tris(bromomethy)lbenzene (PMMA-(br)$_2$) by anionic polymerization. Then, the bromide end groups transformed to azide group (PMMA-(N_3)$_2$). For the synthesis (P3HT)$_2$-*b*-PMMA, click reaction between ethynyl-capped P3HT and PMMA-(N_3)$_2$ was performed. The optical property and thin film morphology of (P3HT)$_2$-*b*-PMMA were investigated by using UV-Vis spectra and atomic force microscopy, respectively.

Session C35 DCMP: Superconductivity: Vortices I 343 - Timir Datta, University of South Carolina

2:30PM C35.00001 Strongly Enhanced Vortex Pinning by Conformal Crystal Arrays , DIPANJAN RAY, University of Notre Dame, CYNTHIA REICHHARDT, Los Alamos National Laboratory, BOLDIZSAR JANKO, University of Notre Dame, CHARLES REICHHARDT, Los Alamos National Laboratory — Conformal crystals are non-uniform structures created by a conformal transformation of regular two-dimensional lattices. We show that gradient-driven vortices interacting with a conformal pinning array exhibit substantially stronger pinning effects over a much larger range of field than found for random or periodic pinning arrangements. The pinning enhancement is partially due to matching of the critical flux gradient with the pinning gradient, but the preservation of the sixfold ordering in the conformally transformed hexagonal lattice plays a crucial role. Our results can be generalized to a wide class of gradient-driven interacting particle systems such as colloids on optical trap arrays.

2:42PM C35.00002 Vortex Pinning in Superconducting MoGe Films Containing Conformal Arrays of Nanoscale Holes and Magnetic Dots , Y.L. WANG, MSD, Argonne National Lab, IL, USA, M.L. LATIMER, Z.L. XIAO, MSD, Argonne National Lab and Department of Physics, Northern Illinois University, L.E. OCOLA, R. DIVAN, CNM, Argonne National Lab, IL, USA, U. WELP, G.W. CRABTREE, W.K. KWOK, MSD, Argonne National Lab, IL, USA — Recent numerical simulations by Ray et al. predict that a conformal pinning array can produce stronger vortex pinning effect than other pinning structures with an equivalent density of pinning sites [1]. Here we present experimental investigations on conformal pinning structures. Direct and conformal pinning arrays of triangular and square lattices were introduced into MoGe superconducting films using focused-ion-beam milling or electron-beam lithography. Transport measurements on critical currents and magnetoresistances were carried out on these samples to reveal the advantages of conformal pinnings. Effects of random pinnings with the same average density were also studied for comparison. Details on sample fabrications and effects of pinning types (holes versus magnetic dots) will be presented. 2:54PM C35.00003 Matching of the Flux Lattice to Geometrically Frustrated Pinning Arrays[1] , J. TRASTOY, R. BERNARD, J. BRIATICO, J.E. VILLEGAS, Unite Mixte de Physique CNRS/Thales, France, J. LESUEUR, LPEM, CNRS-ESPCI, France, C. ULYSSE, G. FAINI, CNRS, LPN, France — We use vortex dynamics on artificial nanoscale energy landscapes as a model to experimentally investigate a problem inspired by "spin ice" systems. In particular, we study the matching of the flux lattice to pinning arrays in which the geometrical frustration is expected to impede a unique stable vortex configuration and to promote metastability. This is done with YBCO films in which the nanoscale vortex energy landscape is fabricated via masked ion irradiation. Surprisingly, we found that minimal changes in the distance between pinning sites lead to the suppression of some of the magneto-resistance matching effects, that is, for certain well-defined vortex densities. This effect strongly depends on the temperature. We argue that this behavior can be explained considering the arrays' geometrical frustration and the thermally activated reconfiguration of the vortex lattice between isoenergetic states.

3:06PM C35.00004 Critical currents, magnetic relaxation and pinning in Nd$Ba_2Cu_3O_{7-\delta}$ films with BaZrO_3 generated columnar defects[1] , A.O. IJADUOLA, Department of Physics, North Georgia College and State University, S.H. WEE, A. GOYAL, P.M. MARTIN, J. LI, Oak Ridge National Laboratory, J.R. THOMPSON, Department of Physics, University of Tennessee, D.K. CHRISTEN, Oak Ridge National Laboratory — The critical current density J_c and the magnetic relaxation (creep) properties have been studied for a set of $NdBa_2Cu_3O_{7-\delta}$(NdBCO) films doped with $BaZrO_3$ (BZO) nanoparticles to form columnar defects. The dependence of J_c on the magnitude and orientation of the applied magnetic field H_{app} (0-6.5 T) and temperature T (5 K-T_c) was investigated. The normalized flux-creep rate $S = -dln(J)/dln(t)$ was determined as a function of T. The current dependence of the effective activation energy $U_{eff}(J)$ was derived using the formalism developed by Maley. The results are well described by an inverse power law type barrier of the form $U_{eff}(J) \sim U_0(J_0/J)^{\mu}$ with fitted values for the pinning energy scale U_0 and the glassy exponent μ. When comparing values for these parameters in the BZO-doped samples with those for their undoped control counterparts, the most striking difference is the larger scale of current density J_0 in the doped samples (a factor of 2.4 higher), while the other pinning parameters do not differ strongly. In the BZO-doped materials, the pinning energy scale U_0 increases with vortex density and J_0 decreases, with both following simple power law dependences on the field.

3:18PM C35.00005 Polaronic pinning of vortex in magnetic superconductors and magnetic-superconducting multilayers[1] , SHI-ZENG LIN, LEV BULAEVSKII, Los Alamos National Laboratory — We present a new type of vortex pinning by enhancing the viscosity of vortex in magnetic superconductors with long relaxation time of magnetization and large magnetic susceptibility. In the absence of current, vortices are dressed by nonuniform magnetic polarization and form vortex-polarons. Under a small current and consequently low Lorentz force, the magnetic polarization follows the vortex motion. However, at long magnetic relaxation time of magnetization, there is additional dragging force by the magnetization besides the Bardeen-Stephen one, thus the effective viscosity of vortex is significantly enhanced resulting in suppression of dissipation. For a large current, the magnetic polarization cannot follow the vortex motion and the vortex-polaron dissociates, i.e. the magnetization and vortex become decoupled. In the IV characteristic, the decoupling transition shows as a voltage jump and can be identified as a depinning transition. The polaronic pinning mechanism successfully explains the observed enhancement of critical current in the ErNiBC superconductor at low temperatures. The polaronic pinning can be optimized in magnetic-superconducting multilayers. We show also that vortex-polaron creep is suppressed at low temperatures.

3:42PM C35.00007 Role of twin boundaries on the vortex dynamics in CSD YBCO nanocomposites[1] , V. ROUCO, A. PALAU, M. COLL, R. GUZMAN, J. GAZQUEZ, S. YE, A. LLORDES, J. ARBIOL, S. RICART, X. OBRADORS, T. PUIG, Institut de Ciencia de Materials de Barcelona - CSIC — Vortex pinning landscape engineering is foreseen as the route to high performance YBCO coated conductors at high fields. Solution-derived nanocomposites with randomly oriented nanoparticles were shown to be an excellent low cost option with huge isotropic pinning forces associated to a highly dense defect structure. We find that the local strain ensuing from the partial dislocation associated to intergrowths breaks the vertical coherence of twin boundaries (TB) and reduce the TB spacing. The lack of TB coherence will affect their role as pinning centers or channels for easy vortex flow. Transport measurements at different temperatures and magnetic fields realized in tracks with different crystallographic orientations has enabled to determine the effect of TB in a quantitative manner and establish their contribution (pinning and/or channeling) in a H-T diagram. We show that the anisotropic pinning coming from TBs has a minor role compared with the huge enhancement of isotropic pinning in nanocomposites. On the contrary, we demonstrate that the reduction of the TB vertical coherence has a relevant effect on precluding vortex channelling at low temperatures avoiding a J_c suppression for field parallel to the c-axis.

3:54PM C35.00008 Vortex dynamics in YBCO films with engineered antidots and ferromagnetic Nanostructures , A. PALAU, V. ROUCO, J.C. GONZÁLEZ, C. MONTON, T. PUIG, X. OBRADORS, Institut de Ciència de Materials de Barcelona CSIC, Bellaterra, Spain, R. CÓRDOBA, J.M. DE TERESA, Instituto de Nanociencia de Aragón, Univ. Zaragoza, E-50009, Spain — Understanding vortex pinning mechanisms and the interaction between vortices and defects is still one of the major goals to enhance properties of nanostructured superconductors. We have used high resolution lithography techniques (FIB, EBL and C-AFM) to create artificial pinning sites in YBCO films. Model systems with antidots and blind antidots with different geometries, distribution and density have been generated. Moreover, with the aim to study interactions in hybrid superconductor-ferromagnetic systems we have filled the antidots with cobalt rods by focused electron beam induced deposition. In-field critical current measurements have been performed in a wide temperature (T) and magnetic field (H) range in order to study vortex dynamics in these novel systems. As far as YBCO films with blind antidots, collective guided vortex motion is observed when we generate spatial asymmetric (ratchet) pinning potentials. By tuning H and T, the vortices undertake the single vortex pinning to vortex-vortex interaction transition which determines the region where the ratchet effect is activated. As far as YBCO films with ferromagnetic rods, we demonstrate a clear interaction between the magnetic field generated by the cobalt nano-rods and the superconducting matrix.

4:06PM C35.00009 Non-equlibrium relaxation of vortex lines in disordered type-II superconductors[1] , ULRICH DOBRAMYSL, HIBA ASSI, MICHEL PLEIMLING, UWE C. TÄUBER, Department of Physics, Virginia Tech — Vortex matter in disordered type-II superconductors display a remarkable wealth of behavior, ranging from hexagonally arranged crystals and a vortex liquid to glassy phases. The type and strength of the disorder has a profound influence on the structural properties of the vortex matter: Randomly distributed weak point pinning sites lead to the destruction of long range order and a Bragg glass phase; correlated, columnar disorder can yield a Bose glass phase with infinite tilt modulus. We employ a three-dimensional elastic line model and apply a Langevin molecular dynamics algorithm to simulate the dynamics of vortex lines in a dissipative medium. We investigate the relaxation of a system of lines that were initially prepared in an out-of-equilibrium state and characterize the transient behavior via two-time quantities. We vary the disorder type and strength and compare our results for random and columnar disorder.

4:18PM C35.00010 Large Thermal Fluctuation effects on Vortex Matter in Iron Arsenide Superconductors $Ca_{10}(Pt_3As_8)(Fe_2As_2)_5$ and $Ca_{10}(Pt_4As_8)(Fe_2As_2)_5$, OSCAR AYALA-VALENZUELA, JEEHOON KIM, LAONARDO CIVALE, Los Alamos National Laboratory, MPA-CMMS TEAM — At finite temperatures, thermal fluctuations (TF) may allow vortices in a superconductor to jump from one pinning center to another in response to the driving force of the current, even if the current density is lower than the critical current density (J_c). This effect, known as flux creep, is orders of magnitude larger in cuprate HTS than in conventional low critical temperature (T_c) materials, mainly due to the much smaller coherence length and large anisotropy. TF in cuprates also produce melting of the vortex lattice and the appearance of vortex liquid phases (VLP), characterized by J_c =0, near T_c. In general iron-based superconductors (FeSC) also exhibit large vortex fluctuation effects, with creep rates as large as or even larger than cuprates, in spite of the lower T_c. VLP are observed in many of FeSC; their extension and characteristics are topics of extensive current research. We have explored vortex fluctuation effects in single-crystals of the novel FeSC $Ca_{10}(Pt_3As_8)(Fe_2As_2)_5$ and $Ca_{10}(Pt_4As_8)(Fe_2As_2)_5$ by measuring the magnetization and its time decay in a SQUID magnetometer. We found creep rates even higher than in YBCO. We also observed extensive VLP (characterized by a reversible magnetization) that cover most of the mixed state region in the H-T phase diagram, as well as superconducting fluctuations above T_c. These unusually strong fluctuations are a consequence of the very large penetration depth λ, which results in Ginzburg numbers (G_i) higher than in cuprates.
